SCOTTISH HOSPITALS AND MEDICAL SCHOOLS.

SCHOOL OF MEDICINE, EDINBURGH.—The lectures qualify for the University of Edinburgh and the other universities, the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin, and the other medical and public boards.

Fees.—For a first course of lectures, £3 5*s.*; for a second, £2 4*s.*; perpetual, £5 5*s.* To those who have already attended a first course in Edinburgh the perpetual fee is £2 4*s.* Practical Anatomy (six months' course), £3 3*s.*; course of demonstrations, £2 2*s.*; perpetual, £4 4*s.* Practical Anatomy, with course of demonstrations, £4 4*s.* Practical Chemistry, £3 3*s.* Analytical Chemistry, £2 a month, £5 for three months, or £10 for six months. Practical Materia Medica, including Practical Pharmacy and Diseases of the Ear, Diseases of Children, Diseases of the Skin, each £2 2*s.* Vaccination, £1 1*s.* For summer courses of Clinical Surgery and Clinical Medicine, each £2 4*s.*; Practical Anatomy, including Anatomical Demonstrations, Operative Surgery, and Practical Medicine, and Medical Diagnosis, each £2 2*s.*; Insanity, £1 1*s.* The minimum cost of the education in this School of Medicine for the double qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons, including the fees for the joint examination, is £95; whilst the minimum cost for the single qualification of either Physician or Surgeon, including fee for examination, is £85.

EDINBURGH SCHOOL OF MEDICINE AND PHARMACY, Marshall-street, Nicolson-square. — The classes of this school will be resumed for the winter session on Oct. 28th. Chemistry, Midwifery, Surgery, and Medicine. From the Dispensary attached to this institution, Pharmacy, Practical and Theoretical, Practical Midwifery. Out-door Practice, and Surgical Diagnosis. Attendance at this institution qualifies for the University of Edinburgh and all other Licensing Boards. Tutorial classes in all the branches of the medical curriculum. Preliminary Medical Classes, 11 A.M. to 4 P.M., and in the evening; Theoretical Chemistry, 10 A.M. to 11 A.M.; Theoretical Midwifery, Dr. C. Bell, 11 A.M. to 12 A.M.; Theoretical Pharmacy, R. Urquhart, 3 P.M to 4 P.M.; Class for Surgical Diagnosis, 3 P.M. to 4 P.M.; Practical Midwifery and Out-door Practice at the Dispensary, 2 P.M. to 4 P.M., under the supervision of Drs. Bell, Troup, Maciver, Baviston, and Stewart; Practical Pharmacy, 2 to 4 and 7 to 8 P.M.; Practical and Analytical Chemistry, 9 A.M. to 5 P.M.; Class for Practical Medicine, 2 P.M. to 3 P.M. The Pharmaceutical Section of this School will open on Oct. 1st. Particulars of R. Urquhart, Secretary.

ROYAL INFIRMARY, EDINBURGH.—Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, &c., and in the surgical department on Diseases of the Eye, the Ear, and Larynx. Separate wards are devoted to fever, venereal diseases, diseases of women, diseases of the eye, also to cases of incidental dilirium or insanity. Post-mortem examinations are conducted in the anatomical theatre by the pathologist, who also gives practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6*s.*; six months, £4 4*s.*; three months, £2 2*s.*; monthly, £1 1*s.*. Separate payments amounting to £12 12*s.* entitle the student to a perpetual ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows:—1. Resident physicians and surgeons are appointed, and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Special non-resident clerks are appointed for such periods and under such conditions as may be deemed expedient. 3. Each surgeon appoints his own dressers, the appointment being for six months. 4. Assistants in the Pathological Department are appointed by the pathologist.

ANDERSON'S COLLEGE, GLASGOW.—The following courses are given, which qualify for all the licensing boards: In winter, Anatomy, Chemistry, Physiology, Surgery, Medicine, Materia Medica, Mechanical Dentistry, &c. In summer, Midwifery, Medical Jurisprudence, Botany, Hygiene, Dental Anatomy, Surgery, &c. The Chemical Laboratory is open daily from 10 to 5. Students of the College are admitted to the practice of the Ophthalmic Institution on payment of a matriculation fee of 5*s.*

Fees.—Each course of lectures (except Anatomy), first session, £2 2*s.*; second session, £1 1*s.*; afterwards free. Anatomy (including Dissecting-room), first session, £4 4*s.*; second session, £4 4*s.*; third session and perpetual, £1 1*s.*; summer (including Practical Anatomy), £1 11*s.* 6*d.*; Practical Anatomy only, £1 1*s.*; Osteology, £1 1*s.*; Dental courses, each £2 2*s.*; Fee for two years' curriculum at Dental Hospital, £10 10*s.* Students who have attended classes at other schools will be admitted to such classes as they may have attended elsewhere at reduced fees. Fees for all the Lectures and Hospital Practice required of candidates for the diplomas of Physician and Surgeon, £48.

GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.—The winter session will open on October 30th. Courses of lectures are given on all the subjects required by the licensing bodies for qualification, and lectures and demonstrations are also given on Practical Physiology, Operative Surgery, Aural Surgery, Dental Surgery, and Diseases of the Eye. During summer, lectures on Insanity are given by Dr. A. Robertson, in the City Asylum under his charge.

Class Fees.—For each course, first session, £2 2*s.*; second session, and perpetual, £1 1*s.* Anatomy: First winter session, £4 4*s.*; summer session, £1 11*s.* 6*d.*; second winter session, £4 4*s.*; afterwards the fee for lectures and practical anatomy is £1 11*s.* 6*d.* per session. Lectures on Diseases of the Ear, £1 1*s.*; with clinique to those not students of the hospital, £2 2*s.* Dental Dispensary free to students of the hospital; to others, £5; first year, perpetual, £10. Lectures on the Eye, £1 1*s.*

GLASGOW ROYAL INFIRMARY.—Number of beds, 532. In addition to the ordinary medical and surgical wards, there are separate wards for the treatment of Venereal Diseases and the Diseases of Women, whilst Diseases of the Eye, Ear, Throat, and Teeth are specially treated at the Dispensary. Courses of clinical medicine and surgery are given by the physicians and surgeons; instruction in pathological anatomy and histology is given by the pathologist.

Appointments.—There are five physicians' and five surgeons' assistants. These appointments are free, and can be held for six months; they are open to students who have passed all their examinations except the last, or to gentlemen who have a qualification in medicine or surgery. Clinical assistants, dressers, dispensary clerks, and pathological assistants are selected from the students without additional fee.

Fees for Hospital Practice and Clinical Lectures.—First year, £10 10*s.*; second year, £10 10*s.*; afterwards free. For six months, £6 6*s.*; three months, £4 4*s.* Vaccination certicates, £1 1*s.*

GLASGOW HOSPITAL AND DISPENSARY FOR THE DISEASES OF THE EAR, 239 and 241, Buchanan-street.—Senior Consulting Physician: Dr. R. Scott Orr. Senior Consulting Surgeon: Dr. James Morton. Consulting Dental Surgeon: Dr. J. Cowan Woodburn. Pathologist: Dr. Joseph Coats. Physicians: Dr. A. K. Irvine, Dr. A. L. Kelly, Dr. J. Gardner. Aural Surgeon: Dr. Thomas Barr. Assistant Aural Surgeon: Dr. James Erskine. Number of cases treated annually, 3600.

The hospital, which contains twelve beds for in-door patients, is always open for urgent cases. Hours of surgeons' visits, 2 P.M. daily; clinical teaching daily. Out-door patients are seen on Mondays, Tuesdays, Thursdays, and Fridays, at 2 P.M., by Dr. Barr, and assistant; and operations and special demonstrations to students and practitioners on Thursdays, from 3 to 4 P.M. Adam Sutherland, 75, West Nile-street, Secretary.

GLASGOW WESTERN MEDICAL SCHOOL, University-avenue, Hillhead.—The winter session will open on October 30th. The school is situated close to the Western Infirmary, where students obtain their Hospital Practice and Clinical Lectures. The class-rooms have been newly arranged and enlarged. The attention of students is directed to the unusual facilities presented for the study of practical anatomy and operative surgery, the supply of subjects being practically unlimited. The dissecting-rooms are open for work from the beginning of October till the end of July.

The lectures qualify for the University of Glasgow in accordance with the regulations, the Faculty of Physicians and Surgeons, Glasgow, and the other corporations.

Class Fees.—For each course of lectures, first session,

Digitized by Google

£2 2s.; second session, £1 1s. Students who have attended a first course elsewhere pay £1 1s. Anatomy, including practical anatomy, £4 4s. Summer session, £1 11s. 6d.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 400. Special wards are set apart for Diseases of Women and for Cutaneous Affections. In the out-patient department there are special cliniques for Diseases of Women and for Diseases of the Throat, Ear, and Teeth. The Clinical Courses are given by the Physicians and Surgeons, each of whom conducts a separate class, and students may attend whichever they select at the beginning of the session. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department a systematic course is given in the winter and a practical course in the summer; these are likewise recognised by the University for graduation. Eight resident assistants are appointed annually, without fee, from those who have completed their course. The fee for the hospital practice, including the various courses of clinical instruction, is twenty guineas in one payment, or in two equal instalments for the first and second years; for six months, seven guineas; and for three months, four guineas.

GLASGOW HOSPITAL FOR SICK CHILDREN, situated at Garnet-hill, was opened last year, and is now available to Medical Students for Clinical instruction in the diseases peculiar to childhood. The hospital includes 57 beds for non-infectious cases only, and is visited by the following physicians and surgeons—viz.: Drs. Leishman, Finlayson, Cameron, and Macewen. It is expected that an out-patient department will be opened in the course of the year.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street.—40 beds. Clinical and systematic course of lectures for students during the winter and summer sessions. Acting Surgeon: Dr. Wolfe.

ABERDEEN ROYAL INFIRMARY.—Contains about 250 beds. Consulting Physician: Dr. A. Harvey. Physicians: Drs. J. W. F. Smith-Shand, R. Beveridge, and Angus Fraser. Surgeons: Messrs. A. Ogston, J. O. Will, R. J. Garden, and John Hall. Ophthalmic Surgeon: Dr. Alex. D. Davidson. Dental Surgeon: Dr. Williamson. Resident Superintendent and Apothecary: Dr. T. Collins. Treasurer and Secretary: Mr. W. Carnie.

THE ABERDEEN ROYAL LUNATIC ASYLUM contains about 540 beds. Physician: Dr. Robert Jamieson. Clinical instruction is given to students during three months in summer.

IRISH HOSPITALS AND MEDICAL SCHOOLS.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Belfast.—Eight Junior Scholarships have been founded in the Faculty of Medicine, of the annual value of £25 each. Two are tenable by Matriculated Students commencing the first, second, third, and fourth years of their course respectively. The Examinations for Junior Scholarships of the second and third years in the Faculty of Medicine take place at the commencement of the second and third years of their medical course. Matriculated Students in Medicine intending to compete for Medical Scholarships of the second year must be of not more than one year's standing as Students of Medicine, and must have attended in some of the Queen's Colleges, or in a University capable of granting degrees in Medicine, two at least of the following courses—viz.: Chemistry, Botany and Zoology, Anatomy and Physiology, Materia Medica and Pharmacy, Practical Chemistry, Practical Anatomy. Matriculated Students in Medicine intending to compete for Medical Scholarships of the third year must be of two years' standing, and not more, and must have attended in some of the Queen's Colleges or in a University capable of granting degrees in Medicine, four at least of the following courses—viz.: Chemistry, Botany and Zoology, Anatomy and Physiology, Materia Medica and Pharmacy, Practical Chemistry, Practical Anatomy. Matriculated Students in Medicine intending to compete for Medical Scholarships of the fourth year must be of three years' standing, and not more, and must, in addition to the qualifications prescribed above, have attended, in their third year, two at least of the following courses—viz.: Theory and Practice of Medicine, Theory and Practice of Surgery, Midwifery and Diseases of Women and Children.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Cork.—The building is provided with a very large, well-ventilated dissecting-room, with physiological and toxicological laboratories, materia medica, anatomical and pathological museums, as well as a room for surgical and obstetrical instruments and appliances. There are well-appointed physical and chemical laboratories, and a large natural history museum in the adjoining building; and part of the College ground is laid out as a botanical garden. The plant houses are now completed and well filled with plants, and are open to the students in the class of Botany.

Fees.—For Practical Anatomy, £3, for Practical Chemistry, £3, each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course. Eight scholarships (value about £30 each), as well as several exhibitions and class prizes, are awarded every year.

SIR PATRICK DUN'S HOSPITAL, Dublin (in connexion with the School of Physic).—Consulting Surgeon: Dr. William Colles. Physicians: Drs. John Mallet Purser, J. Magee Finny, and J. R. Kirkpatrick (Midwifery Physician). Surgeons: Drs. Charles Ball, Edward H. Bennett, and Thomas Evelyn Little.

The payment of £3 3s. to the hospital entitles any student to attend the clinic of the hospital for twelve months, and to attend the lectures delivered by Dr. R. G. Butcher, University Lecturer in Operative Surgery. Students who have taken out the degrees of Bachelor in Medicine and Master in Surgery in Trinity College are entitled to attend the hospital as perpetual free pupils.

Clinical Lectures are delivered in the hospital theatre at ten o'clock on Mondays and Tuesdays. In addition to the hospital fee, the payment of a fee of £9 9s. is required for the privilege of attending these lectures. Total fees for hospital and lectures for twelve months, £12 12s.

Sir Patrick Dun's Maternity.—Total fees for college students, £3 3s. Total fees for externs, £6 6s.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street, Dublin.—Fee for nine months' Hospital attendance, £12 12s.; six months', £8 8s. Summer, three months', £5 5s.

Three resident pupils are selected half-yearly. At the termination of the session, prizes in Clinical Medicine and Surgery, in Obstetric Medicine, and in Ophthalmic Surgery will be awarded.

Hudson Scholarship.—In addition to the junior prizes, the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in Clinical Medicine and Medical Pathology, Clinical Surgery and Surgical Pathology, Pathological Histology, Surgical Appliances, including instruments and bandaging, Ophthalmology, and Gynæcology.

The certificates of attendance are recognised by all the Universities and Licensing Bodies in the United Kingdom.

LEDWICH SCHOOL OF SURGERY AND MEDICINE, Peter-street, Dublin (formerly original School of Anatomy, Medicine, and Surgery).—There are endowments in favour of students, subject to conditions prescribed by the founder, in the following departments:—Two in Anatomy and Physiology; two in Minute Anatomy; two in Practical Anatomy; one in Surgery. Certificates of attendance on these lectures are received by the various examining boards; by the Apothecaries' Halls of Dublin and London; by the King and Queen's College of Physicians in Ireland; by the Royal Colleges of Physicians, London and Edinburgh; by the Royal University, the Universities of Dublin, London, and Glasgow; by the Glasgow Faculty of Physicians and Surgeons; and by the Queen's University in Ireland. The Senate of the Royal University having recognised the lectures of this school, arrangements have been made to educate students for its Medical and Surgical Degrees in accordance with its requirements. This school is in a central situation, and is replete with every convenience for study and successful instruction. By its teachers it is connected with nine hospitals, four of which are Medical and Surgical hospitals, one for Fever, one for Midwifery and Diseases of Women and Children, one for Diseases of the Eye and Ear, &c.

Returns for the session 1884-85 have not been received from this school.

Digitized by Google

CARMICHAEL COLLEGE, Aungier-street, Dublin.—The following scholarships, &c, are awarded to students entering for an *annus medicus* for the current year:—The Carmichael Scholarships, value £15 and £10; the Mayne Scholarship, value £15; Class Prizes, £10, £7, £5, £4, £3, and £2; also twelve Lecture Prizes, value £3 each.

DR. STEEVENS'S HOSPITAL.—This hospital, containing beds for 250 patients, is situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, occupying a position in the centre of one of the busiest manufacturing districts of the city, otherwise unprovided with medical institutions. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane. The hospital is easily accessible by two lines of tramways, and owing to its position affords exceptional advantages for clinical instruction. There is a ward entirely devoted to Syphilitic Disease, a detached building for Fever cases, and an extensive Out-patient Department, with separate Clinics for Diseases of the Skin, Throat, Teeth, and those peculiar to Women. The hospital is visited daily, at half past eight A.M., by the resident surgeon, and at nine A.M. by the physicians and surgeons. The Surgical wards are also visited each evening. Clinical Lectures are given by the physicians and surgeons during the session. There is accommodation in the hospital for two medical and six surgical resident clinical assistants, who, in addition to their rooms and furniture, are provided with coal and gas.

Fees.—Hospital Practice: Nine months, £12 12*s.*; six months, £8 8*s.*; three months, £5 5*s.* Dressership—Winter, six months, £21; summer, do., £15 15*s.*

MATER MISERICORDIÆ HOSPITAL, Dublin.—This hospital contains 230 beds, 50 beds being specially reserved for patients suffering from fever and other contagious diseases. Two Clinical Lectures will be delivered in each week, in addition to the daily bedside instruction. A special course of lectures on Fever will be given. A certificate of attendance upon this course, to meet the requirements of the King and Queen's College of Physicians, may be obtained. A ward has been assigned for the treatment of Ophthalmic Diseases. Opportunities are afforded for the study of Diseases of Women in the ward under the care of the Obstetric Physician, and at the dispensary held on Wednesdays and Fridays during the session. Lectures on Clinical Gynæcology will be delivered on Wednesdays. "Leonard Prizes" (Clinical): Prizes of the value of thirty pounds will be given at the end of the winter session, in accordance with the directions contained in the will of the late Mark Leonard, Esq. Certificates of attendance upon this hospital are recognised by the Royal University and all the Licensing Bodies in the United Kingdom. *Fees:* Nine months, £12 12*s.*; six winter months, £8 8*s.*; three summer months, £5 5*s.*

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, North Brunswick-street, Dublin.

These hospitals contain 312 beds—110 for Surgical cases, 82 for Medical cases, and 120 for Fever and other epidemic diseases.

There will be a distinct course of Lectures and Clinical Instruction in Fevers. Operations are performed on Monday and Wednesday mornings, except in cases of emergency. A course of Practical Instruction in Ophthalmic Surgery will be given. Fee for the Certificate, three guineas.

A Resident Surgeon is appointed every alternate year, receives a salary, and holds office for two years. Eight Resident Clinical Clerks are appointed each half-year, and provided with furnished apartments, fuel, &c., &c. These appointments are open not only to advanced students, as formerly, but also to those who are qualified in Medicine or Surgery. Dressers are selected from among the best qualified of the pupils, without the payment of additional fee.

COOMBE LYING-IN HOSPITAL, AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN.—The hospital contains 65 beds, and has also a large extern maternity attached. Nearly 3000 confinements are attended annually by the pupils of the hospital. A special dispensary for diseases peculiar to women is held daily, and clinical instruction given. The certificates of the hospital are recognised by all licensing bodies, and its diploma is accepted by the Local Government Board, &c. Further particulars can be learned from the registrar.

ROTUNDA HOSPITAL, Rutland-square, Dublin.—This institution consists of two distinct hospitals—namely, the Lying-in Hospital and the Auxiliary Hospital, the latter for the reception of patients suffering from uterine and ovarian diseases. There is also a large extern maternity in connexion with the hospital, and a dispensary for diseases peculiar to women, which is open daily. Clinical instruction is given daily (Saturdays excepted), in midwifery and the diseases peculiar to women, special attention being directed to the application of antiseptics in midwifery, and lectures on these subjects are delivered regularly throughout the session. Accommodation is provided for a limited number of intern pupils.

MEDICAL TEACHERS.

DR. ALTSCHUL has made Stuttering, Lisping, Falsetto, recent or of long standing, due to Nervousness, &c., irrespective of age or sex (without any mechanical appliances), his special, life-long study. The voice developed and strengthened.—9, Old Bond-street, W.; and at Brighton and Hastings.

Mr. J. BECKTON, C.M., prepares candidates for the London Matriculation, Medical and Law Preliminary, University, Local, and other Examinations. Boarders received.—41, Torrington-square, W.C.

Mr. L. BRYAN, M.A. Cantab., continues for the eleventh year his most successful preparation of resident and non-resident students for Matriculation and the Medical Preliminaries. Students entering at any of the hospitals are taken as boarders and receive careful supervision, every home comfort, and assistance in their professional studies.—140, Gower-street, W.C.

Mr. H. CAMPBELL, M.B., B.S. Lond., M.R.C.S., prepares candidates for the Colleges of Physicians and Surgeons, the Hall, and other Professional Examinations.—64, Guilford-street, Russell-square, W.C.

Mr. H. CRASWELLER, B.A., prepares candidates for Medical and Law Preliminaries and Matriculation.—89, Down's-park-road, Clapton.

Mr. A. H. DAWES, 1st B.A. Lond., gives lessons privately, in class or by post, in preparation for the London Matriculation and Medical Preliminary Examinations.—Adderstone, Vardens-road, New Wandsworth (close to Clapham Junction station).

Dr. EBERLE (Thirsk, Yorks), late Principal of the Easingwold Medical College, Author of "Students' Medicine," &c. &c.—Gentlemen prepared for the Preliminary Examination in Arts of the Universities, any of the Professions and Services, also for the Primary, Pass, and Competitive Examinations. Personal and special attention directed to the assistance of Practitioners, Assistants, and others, by letter.

Mr. S. ELLIOTT, B.A. Lond., prepares for Matriculation and Degree Examinations, Law, Medical, and other Preliminaries.—Emery Hill's Hospital, Rochester-row, S.W. (near Victoria Station).

Mr. J. GIBSON, M.A., prepares candidates for the London Matriculation, and Preliminary Medical and Legal Examinations.—24, Chancery-lane, E.C.

Dr. N. HEINEMANN, F.R.G.S., F.R.Hist.Soc., prepares for the Preliminary Examinations &c.—80, Upper Gloucester-place, Portman-square, London.

Dr. CRESSWELL HEWETT prepares candidates for the M.D. Brussels, the Services, and other Professional Examinations.—5A, London-street, Norfolk-square, W.

Mr. THOMAS LYLE, M.A., F.R.Hist.S., of the London and Dublin Universities, prepares gentlemen, resident and non-resident, for the various Preliminary Arts Examinations and Matriculation at the London University.—Grove House, Shacklewell-lane, London, N.E.

Mr. J. W. SAUNDERS, A.P.S., G.S.T., prepares gentlemen for Examination in Anatomy, Physiology, Botany, Chemistry, Materia Medica, Pharmacy, &c.—6, Rochester-square (late Camden-road), N.W.

Mr. H. SERGEANT, B.A. Lond., holds special classes for London University Matriculation, the Preliminary Medical Examinations, &c.—8, High-street, Camden-town, N.W.

Mr. BUTLER SMITH assists pupils in reading up for the London Matriculation, and Legal, Medical, and Pharmaceutical Examinations.—Polytechnic, Regent-street, W.

Mr. H. WAITE prepares pupils for Matriculation, Preliminary Scientific, and the Examinations for Medical Registration of all the licensing bodies.—135, Strand, W.C.

Mr. F. A. WHITE, B.A., prepares candidates for Matriculation and Medical and Legal Preliminary Examinations.—83, Hereford-road, Bayswater, W.

Mr. MAURICE WILLIAMS prepares candidates for Examination in Theoretical and Practical Chemistry, Materia Medica, &c.—5, King-street, Finsbury-square.

Mr. J. WOODLAND, F.L.S., F.C.S., holds classes and demonstrations in Practical and Theoretical Chemistry, Chemical Physics, Materia Medica, and Pharmacy; in the Botanical classes specimens are supplied to each student, and all apparatus is found for the Practical Chemistry course. These classes are held for candidates for the Primary L.R.C.P., L.S.A., and the M.B. degree of the different Universities, at the Central School of Chemistry, 173, Marylebone-road, N.W.

To Correspondents.

WE tender our best thanks to those gentlemen who have kindly supplied us with the returns and prospectuses upon which the information given in this Students' Number of THE LANCET relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom is based.

The present number being exclusively devoted to information especially interesting to students, we are necessarily compelled to defer the publication of communications on other important subjects.

ABSTRACT OF A

Clinical Lecture

ON A

CASE WHERE A SCIRRHOUS CARCINOMA OF THE PROSTATE WAS REMOVED.

Delivered at the Liverpool Royal Infirmary,

BY REGINALD HARRISON, F.R.C.S.,
SURGEON TO THE INFIRMARY.

GENTLEMEN,—About twelve months ago I brought under your notice two specimens of large adenomas of the prostate which had been successfully removed in the course of operations for lateral lithotomy. Both of the patients now remain perfectly well, and have shown no signs either of a recurrence of the prostatic growths or a re-formation of calculi. One of these cases was at the period referred to under my care in the infirmary, when you had the opportunity of watching what was done for the patient. I have since learnt from his medical attendant, Dr. Samuels of this city, that he has continued to enjoy good health. The other case occurred in the practice of Mr. Bickersteth, who kindly allowed me to show the tumour removed, which will be found in our museum. Four years after this operation Mr. Bickersteth knew that the patient was in the enjoyment of perfect health. The size of the tumours in these cases and the process of enucleation which was employed in their removal distinguished them, in my opinion, from the majority of instances where portions of hypertrophied prostate have been accidentally detached in the course of operations for stone, or have come away between the blades of the forceps. So important did I consider these cases, in conjunction with others that may be found scattered through surgical records, that I then ventured to draw the following conclusions:—

1. That in some cases of enlargement of the prostate attended with pressing symptoms of distress otherwise irremediable, it might be expedient to practise digital exploration of the gland, such as the operations as for lithotomy permitted. 2. That this proceeding might permit of the safe removal of the whole or a portion of the growths with such advantage to the patients as was illustrated in the cases that I brought forward. 3. That the operation of exploration, even if it did not permit of the removal of the growth, would relieve the patient's symptoms so far as micturition was concerned. Mr. Lund's important case of prostatotomy[1] furnished a good illustration of this.

In continuation of this subject I will proceed to narrate the particulars of the case I am bringing under your notice to-day; after which the patient will be introduced.

J. B——, aged sixty-four, came under my observation in August, 1882. His chief symptoms related to hæmaturia and frequency in micturition. The patient had up to nine months previously enjoyed good health. There was no history either of syphilis or tubercle. Two months ago he noticed that his left testicle became swollen. This was strapped, when the swelling passed to the right one, which was considerably enlarged on his admission to the infirmary. On exploration by the rectum the prostate was found somewhat enlarged, indurated, and nodulated. On examination with a sound some obstruction was revealed in the prostatic urethra, but neither stone nor roughness within the bladder could be detected. He passed urine every two hours or oftener both by day and night, and the urine was largely mixed with blood. Nothing like a villous structure could be detected after careful examination with the microscope of some shreds contained in the urine. The right testicle was somewhat enlarged but uniformly so. No glandular enlargement could be detected. All kinds of treatment were tried; but though matico diminished the quantity of blood in the urine, yet the extreme irritability continued, under which the patient's health was rapidly giving way. Under these circumstances I determined to explore the prostate and neck of the bladder with the finger. On October 25th I opened the membranous urethra as for the median operation for stone. On exploring the prostate I found a solid mass projecting into the urethra and occupying the neck of the bladder. This, with some little trouble and with the assistance of Mr. Rushton Parker, I succeeded in enucleating tolerably completely, though a hard cord-like band in the roof of the prostatic urethra was only imperfectly scraped away with the finger. The mass removed was about the size of the last phalanx of my thumb, and was evidently a new and rare growth. The exploration of the bladder was not as complete as I could have wished, notwithstanding the viscus was well pulled down towards my finger from above the pubes. The removal of the tumour was not attended with any serious hæmorrhage, it not being necessary to tie a vessel. The patient suffered very little from the operation. As the urine now passed entirely through the wound, the patient was able to enjoy what he had not had for many months—namely, uninterrupted sleep. On the third day after the operation the urine was clear from blood and remained so for ten days, when it again returned in a small quantity, and finally disappeared. On Dec. 1st the patient was able to leave the infirmary, the perineal wound having almost entirely healed; he had not complete control over his bladder.

On Dec. 15th he returned to the infirmary for relief, by reason of some preputial irritation which had been caused by the use of a rubber urinal. The dresser's report is as follows:—"The urine is free from blood, and all comes by the urethra.—Dec. 20th: A rubber catheter was tied in the bladder for a few hours daily.—Jan. 8th, 1883: The patient is in much the same condition, but he is able to retain his urine for about half an hour. He was measured by Mr. Reynolds, the surgical instrument maker, for a urinary truss, made after Mr. Harrison's directions, with the view of providing against the incontinence.—12th: The patient was fitted with the truss yesterday afternoon. It consists of an ordinary leather-covered truss-spring, terminating in an ivory ring, well padded, through which the penis is passed, the object being to exercise steady pressure on the urethra immediately below the arch of the pubes. It was found that this apparatus completely restrained the escape of urine and enabled the patient to get about his business with comfort. Before leaving the infirmary on Jan. 24th, it was noticed that so effectual was the truss in controlling the escape of urine, that a slight leakage through the perineal wound took place, which required some few applications of nitrate of silver. On the 19th Mr. Harrison introduced the patient at his clinical lecture for the purpose of demonstrating the use of the urinary truss and in illustration of his remarks relating to the case."

This patient lived comfortably for fourteen months after the operation. He had no recurrence of the hæmorrhage, and partially resumed his occupation as a stevedore; then the glands in his left groin began to enlarge extensively, and in two months more he died.

I am indebted to my dresser, Mr. Cooke, for the notes of this case, and to Mr. Paul for the following report of the tumour:—

"The piece of tumour hardened for microscopical examination was the size of a small filbert, and was rather less than one-half of the whole bulk of what was removed. It was softer and more fleshy in appearance than normal prostate, and was plainly to the naked eye a new growth. Microscopically, the portion examined consists of prostatic tissue, infiltrated with carcinoma, except along one margin, where the normal prostatic structure is unaltered. The growth is spreading both by direct extension along the gland tubes, and as a cellular infiltration of the stroma. The carcinoma is of the acinous variety, the general appearance resembling an ordinary scirrhus of the breast. The cells are from two to three times the size of a pus cell, and some contain more than one nucleus. Those next the basement membrane are in places elongated and more regularly arranged. The alveolar stroma is very rich in cells, and in many places shows a number of non-striated muscular fibres. The growth may be considered to have originated in the prostate, and not to have spread to it from the bladder, as it is very doubtful if an acinous variety of carcinoma ever originates in the latter."

Such, gentlemen, are the chief features, clinical and histological, of a case of more than usual interest and rarity. Though the operation which was performed may not have cured the patient, it has been the means of prolonging life, and rendering its continuation less distressing than it pre-

[1] Trans. International Medical Congress, London, 1881.

Digitized by Google

viously was. That the growth was of a rare kind must be evident to all who have any acquaintance with the enlargements and tumours to which the prostate is liable. That the proceeding adopted was the only means of affording relief I have not the least doubt, nor was the risk incurred a great one to run. On more than one occasion I have opened from the perineum the bladders of persons suffering from malignant disease with considerable benefit. No condition can be more distressing than that of malignancy associated with difficult micturition, hæmorrhage into the bladder, and the constant catheterism that these entail. If my incision in the case brought under your notice to-day had only temporarily relieved these symptoms, the continuance of which could only have brought about a speedy termination, without permitting the removal of the growth, even then something would have been gained by it. The means successfully employed for providing against the incontinence which resulted is also worthy of your attention, as the principle might be extended to other circumstances. I have often noticed how slight a pressure applied over the urethra at the root of the penis will effectually stop micturition. The application of this principle by a truss suggested itself to me as being a likely, if not an entirely novel, means of affording the remedy that was desired.

ON THE

RHEUMATIC ORIGIN AND THE TREATMENT OF CHOREA.

BY OCTAVIUS STURGES, M.D.,
PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE several enumerations with reference to the incidence of rheumatism in chorea which I have communicated to THE LANCET from time to time are now brought to a close, owing to the routine of promotion among the medical staff at the Hospital for Sick Children. I wish, therefore, to make a final communication upon the subject, and to indulge in a retrospect.

Since my last communication (Nov. 10th, 1883), there have been but seventeen cases to add to the 202 already recorded. These furnish four which, upon the principle which has hitherto been pursued, may be put to the rheumatic account—viz., one that had had rheumatic fever, two that had had joint pains presumably rheumatic, and one swelling of the feet and legs not further described, but which we also assume to have been rheumatic. In none of the four did the rheumatism appear to be the immediate cause of the chorea.

The total number of cases, the product of ten years' observation, is thus brought up to 219. Of these sixteen had had rheumatic fever, twenty-five to twenty-eight pains presumably rheumatic, and twelve were without information upon the point. Let us suppose that forty-two were really rheumatic subjects, we should then have the rheumatic proportion represented by very nearly 20 per cent.—hardly more than a third of these being cases of acute rheumatism—and a statement I ventured to make some years ago upon a review of a smaller number of patients that "chorea had nothing to do with rheumatism in three-fourths of the cases," would be still borne out.[1]

But if, without stickling for precise numbers, we assume that from 20 to 25 per cent. fairly represents the rheumatic proportion among choreic children, we have still to consider how that proportion compares with what I have called the *normal* incidence of rheumatism. For it is not (as was urged in my last paper), the percentage of rheumatism taken absolutely which represents the chorea proclivity; it is the excess of this percentage over the normal incidence among children of like age. It was roughly estimated that the normal percentage of rheumatism to be attributed to the community at large was for adults certainly over 12, and possibly over 20 per cent., while for children it was estimated at about 15 per cent. Since that was written my friend Dr. Coutts has taken up a similar inquiry at the East London Hospital for Children, and has been good enough to furnish me with the result in 194 cases, the number collected up to the present time. The method followed was this. The out-patients were taken consecutively and without selection (excepting only infants), the youngest three, the oldest fourteen. The question first asked in each instance was whether or not the child had had any pain in the joints at any time during its life. In case of a negative answer and in the absence of erythema or tonsillitis, the patient was dismissed as probably non-rheumatic. In case of an affirmative reply further questions were put as to the age when the pain first occurred, the joints chiefly affected, the duration of the pain, and whether or not swelling or redness accompanied it; finally, a careful examination was made of the cardiac sounds. By this method the children probably rheumatic got grouped into three classes, (1) those that had had joint pain only, (2) those that had pain with swelling of joints, (3) those that, besides these two, had moreover at the time of examination a cardiac bruit. An inquiry thus carefully devised, and which, instead of applying names, gives the reader the precise material he is in want of, is, as far as possible, secured against error. It has in this case the further advantage of being undertaken by one who has an open mind upon the point at issue.

The general result may be stated as follows. Of the first 100 patients, twelve had chorea, and are therefore excluded. There remain eighty-eight. Of these six had had joint pain and swelling; three had had joint pain with swelling, and had at the time of seeing a cardiac bruit; three had had joint pains without swelling, but had a cardiac bruit; three had had joint pains of an indeterminate kind. Thus, upon the plan of reckoning hitherto followed, fifteen out of the eighty-eight gave evidence of rheumatism; or if the three with joint pain merely be excluded, then twelve out of the eighty-eight. Of the second series of ninety-four; fourteen had chorea, and are accordingly excluded.[2] Of the remaining eighty, five had had joint pain with swelling, and had at the time a bruit; two had had joint pains and swelling; nine had had joint pains only; one had had bruit pains and one had a cardiac bruit. Excluding these two last we have sixteen of the eighty presumably rheumatic. It is true that the numbers with joint pains alone are a large proportion of the whole. Yet even if we assume that more than half of these (five out of the nine) were not truly rheumatic—a concession which is beyond the terms of the calculation—we have still twenty-six rheumatic out of 163 patients. This is more than 15, it is close upon 16 per cent. The figures go to prove that for children in general the allowance of 15 per cent. of rheumatism which was arrived at in my last paper was rather an under- than an over-estimate. It is only the broad conclusions, however, that need be insisted on. They are these—

If, on the one hand, without insisting upon less equivocal evidence of rheumatism, the mere occurrence of pains in the joints be accepted in that light, then such evidence is to be met with in full 15 per cent. of our London children taken as they come, and in about 20 per cent. of choreic children. The statement, therefore, that three-fourths of choreic children have *personally* (the word is needed to keep clear of the question of inheritance) nothing whatever to do with rheumatism has to be supplemented by this further statement. Rheumatism does not befall choreic children exclusively. It is a very wide possession, and here in London falls to the lot of three out of twenty. The special proclivity to chorea arising out of rheumatism is represented, therefore, not by 20 per cent., but by 5 per cent. If, on the other hand, more trustworthy evidence of rheumatism be required than joint pain of itself affords—swelling, redness, and tenderness of the joints (with or without cardiac bruit)[3]—

[1] From the admirable Abstracts of Medical and Surgical Cases, published annually by the Pendlebury Hospital for Sick Children (copies of which have been kindly sent me by Dr. Ashby, the senior physician, and Dr. Chaffey, lately medical officer at that institution), it appears that in the years 1881-83 there were 112 cases of chorea admitted; seventy-seven of these had no rheumatism, eight were doubtful, twelve had had pains doubtfully rheumatic, fifteen were beyond reasonable question rheumatic subjects, four of these having had acute rheumatism. Now, if the above supposition as to the three-fourths proportion be true, eighty-four of these 112 patients should have nothing to do with rheumatism, and seventy-seven are so given by positive statement. We want seven more; and, surely, as many might be allowed us of the twelve [illegible] doubtfully rheumatic and the eight doubtful [illegible] the largest estimate, we find twenty-seven [illegible] than one-fourth. The Collective Investi- [illegible] their Preliminary Report on this subject, have [illegible] less than one-fourth (Collective Investigation [illegible]

[2] As an independent observation, Dr. Coutts in his report remarks upon the very large proportion of chorea which these figures indicate; and expresses the opinion that the affection is unusually prevalent among the children of the poor in East London.

[3] Were the question to be settled upon the evidence of heart murmur, we might say without reserve that almost every choreic child is also rheumatic, for nearly every one at some time or other exhibits this symptom. It is mainly by the varying weight given to it that testimony is so various and conflicting.

Digitized by Google

that is to say, acute polyarthritis, then, whether we take children as they come or choreic children, the percentage of such cases is extremely small (I do not think we are in a position to state it even approximately), although it may, perhaps, be admitted that it is somewhat higher for the choreic than for the non-choreic.

If calculations such as these are anywhere near the truth (they do not profess to be an exact statement of it), it is impossible any longer to represent rheumatism as the grand fact and basis of chorea. Such a view of the affection would be untenable even had we to say that the rheumatic element was more often absent than present. We have to say much more than that. The etiology of chorea must find some broader basis than any that rheumatism affords. And when this is admitted, and rheumatism takes its proper place as one amongst many agencies, predisposing to chorea, if not directly producing it, then and then only can its pathology, and what is much more, its treatment, be rationally determined.

And here I should conclude; but this view of the practical importance of what may seem to some a barren inquiry lengthened beyond measure tempts me to add one word more. These 219 children that have formed the text of these papers were all under close observation for some time, observation which was not confined to the single question of rheumatism, and which spread over more than ten years. And the children had to be treated as well as observed, if possible to be cured. Many of them were stubborn and chronic cases. Many had been under special treatment, chiefly by arsenic, up to the time of their arrival, when such treatment was suspended in favour of that to be presently described. Some few relapsed, but no child had to be sent back to Ormond-street owing to its complaint returning in acute fashion. The majority made rapid improvement from the first. All ultimately recovered. We have thus ten years' unbroken experience, and it is all of one tenour. I do not say that nothing could be better, because there is the element of time to be considered. But does time matter much, or if it did, is it reasonable to expect that an affection of this kind can be cured in a hurry? Chorea is not painful or actively injurious unless you make it so. It is, indeed, in a measure preservative, a signal of distress giving timely warning of overstrain. The business concerns of these little children are not of great moment, and inasmuch as not rheumatism, but nervous shock, overwork, or alarm, or ill usage, is often the direct cause of their complaint, it is inevitable, as the experience of the whole world teaches, that time should be granted as one of the conditions of cure. But putting time out of the question, and taking the entire material dealt with over ten years, we have but one result to record—namely, recovery. That is almost as good as saying that under the treatment adopted chorea always recovers. I put aside that extreme form of the disorder which is so rare that it is impossible to speak precisely about it, but of which, as I have shown elsewhere, the treatment in question can give as good an account as any other; and I say, what other treatment than ours is needed, or, indeed, justifiable, for chorea in general, unless it can claim to reach as good a result in shorter time?

And what is the treatment? If, after saying so much, I were to go on to describe the particular medicinal agent that had been employed, I appeal to the reader's candour to say whether or not he would begin to respect that drug, and admit that a very good case had been made out in its favour. But when I go on to say, as I must, that the treatment adopted was rest, bodily and mental, good food, country air, patience and encouragement, treatment as yet in want of a name, I know very well that, far from putting such treatment upon any equality with drugging, many a reader will turn away as though some deceit or cajolery had been put upon him.

Wimpole-street.

FIRE AT A COUNTY LUNATIC ASYLUM.—On the 15th inst. a fire of an alarming and destructive character occurred in the grounds attached to the Surrey County Lunatic Asylum, Wandsworth Common. The discovery was made among some timber stores, and but little time elapsed before the flames began to make considerable ravages. The firemen had to contend with great difficulties, owing to the great distance of water, of which there was a bad supply from the asylum, and about three hours elapsed before the fire was virtually got under. The cause of the fire is not known.

ON THE

DISEASE OF THE SKIN NAMED "PITYRIASIS MACULATA ET CIRCINATA."

BY T. COLCOTT FOX, M.B. LOND., M.R.C.P.,

PHYSICIAN FOR DISEASES OF THE SKIN TO THE WESTMINSTER HOSPITAL, AND TO THE SKIN DEPARTMENT OF THE PADDINGTON-GREEN CHILDREN'S HOSPITAL.

THE affection under consideration has not hitherto, I believe, been described in England, and my own attention was redirected to it by a paper in the *American Journal of the Medical Sciences* of Oct. 1880, in which Dr. Duhring gives careful independent descriptions of six cases observed by him in adults, and refers to the few existent notices of the affection which he had met with in the course of his researches. I shall deal at present only with the affection as seen in children, because my experience of it in adults is, so far, limited to two cases. Dr. Duhring, in his easily accessible paper, has given exhaustive extracts from the writings of Bazin and Hardy, and of Horand of Lyons, who first described the "pityriasis circiné" in children, so that I shall not repeat these references at length; but whereas Dr. Duhring writes that, "to Bazin, I think, undoubtedly belongs the honour of having first described it," I will establish Gibert's claim by giving the latter's account of pityriasis rosea (referred to by Bazin) from p. 402 of the third edition of the "Traité Pratique des Maladies de la Peau," 1860. C. M. Gibert thus sums up the characters of the disease in adults and youth: "Little furfuraceous, very slightly coloured, itchy, irregular macules, scarcely exceeding a finger-nail in size, numerous and thickly set, although separated always by some interval of healthy skin, distributed upon the upper part of the body and in preference upon the neck, the upper part of the chest, and the upper arms, but possibly invading regions beyond, even to the thighs, in such a manner that the total duration of the eruption, which dies out gradually in the regions first attacked *pari passu* with its further extension, is prolonged ordinarily for six weeks or two months. This eruption, more common in the female than male, is noticed frequently during the warm season. It scarcely shows itself in youth or in persons with a white, thin, and delicate skin." Further on, p. 410, he adds that the little macules are rosy or approaching the colour of erythema if the inflammation be very active, very slightly raised, at first of little extent, but afterwards enlarging, approaching one another, and even coalescing. It is to be remarked that Gibert does not mention the ringed form. He carefully distinguishes the affection from erythema, in which the lesions are less extensive, more prominent and profound, and from psoriasis, in which the plaques are more prominent and injected, rounded and shining, and the scales larger. No fungus was ever found by him.

Bazin[1] writes that it is a trifling idiopathic affection terminating spontaneously by resolution, in acute cases after a duration of from ten to fifteen days, and in others after from six to eight weeks, but never becoming chronic. He mentions the existence of prodromata, and describes a second ringed phase of the eruption. Hardy[2] draws a word picture of the circinate variety. Both writers carefully distinguish the affection from "herpès circiné" (tinea circinata) and psoriasis. So far the eruption was noticed in adults and youth, but in the *Annales de Derm. et Syph.*, tome vii., 1875-76, Horand of Lyons recounts seven cases in children, and his description tallies so closely with the cases I have observed that it was impossible to doubt that I had to deal with the same affection. He, like the other writers, failed to find any fungus, and considers the name "pityriasis circiné" the most suitable. He identifies it with the "pityriasis circiné" of Hardy, but not with the pityriasis circinata of Bazin. Now, Dr. Duhring has brought forward a strong case for grouping all these phases under one heading. With such a limited experience I do not feel in a strong enough position to satisfactorily offer criticisms on this point; but I am quite positive the cases I have seen in children are similar to those Horand described. I will only mention the circumstance that Bazin was very hazy as to what Willan and his followers described

[1] Les Affections Génériques de la Peau, 1862.
[2] Leçons sur les Maladies Dartreuses. Third Ed. 1868.

Digitized by Google

and figured as roseola annulata.[3] Rayer thought it an erythema annulatum, and Bazin, after saying he had never seen it as Bateman describes it, adds, "Roseola annulata is no other, in the majority of cases, than the affection described by us under the name of pityriasis circinata amongst the arthritides pseudo-exanthémiques." Dr. Allan Jamieson of Edinburgh has also noticed the affection. Lastly, I must mention Vidal[4] as a writer who seems to be well acquainted with the affection. In his experience the eruption rarely lasts longer than from five to six weeks, and he observed that the desquamative plaques were preceded for a very short time by raised, congestive, erythematous plaques or papules, not yet exfoliating; and, moreover, that some spots carried quite thick epidermic scales, which separate *en masse*, leaving a little collaret adherent at the periphery, whilst sometimes slight moisture exudes or a little crust forms. In a later paper[5] Vidal further describes a special parasitic form of P. circinata et marginata met with in persons from six and a half to thirty-five years of age, distinct from Gibert's P. rosea. The fungus which he names "microsporon anomœon vel dispar" is very minute, having an average length of a thousandth of a millimetre. The rounded spores have an irregular outline, and lie in irregular masses and groups, very rarely in chains amongst the epithelial cells of the superficial and middle layers of the epidermis, whose cohesion they undermine. Mycelium is absent. Vidal distinguishes this fungus from the minute spores (? Torula vulgaris) so commonly found amongst the epithelial cells of the skin.

Of the five cases which I have recognised without hesitation in children, I will here give a fair example, as all have been marked by a close uniformity.

Blanche G——, aged seven years, came under my care at the Westminster Hospital on January 24th, 1884. Her mother declared she had not suffered from any infectious disease, and that all the other children were well, and continued so. The eruption had existed for three weeks, and was preceded by a fright three days previously, and also a slight cold and sore-throat, but no running from the eyes or nose. The eruption seems to have evolved mainly in the night. The mother stated that the eruption came out in successive crops, increasing for some days; that it appeared first over the back and shoulders, the axillæ and abdomen; that the face was affected later on, and the dorsum of the hands last of all. The scalp also was involved and tender. The spots were moderately itchy, rounded, rosy-red in colour, mostly the size of a split pea, with some smaller ones interspersed. The appetite and general health were excellent. The eruption paled on exposure to the air, but after a bath the colour revived. When I saw the child the face, with the exception of the forehead, the scalp, the neck, the trunk, the arms and hands, except the palms, and the legs down to the knees were covered with thickly disseminated, fading, roseolous, slight desquamating macules about the size of the little finger nail. The mouth was free. The eruption was usually discrete, but over the shoulders, trunk, and back of the neck the eruption was exceedingly closely set, and even coalescent here and there. In some places, chiefly on the limbs, slightly but distinctly raised, faint rosy, crimson or brick-red, freshly evolved macules were conspicuous, from a split pea to a finger nail in size, of rounded or oval but somewhat irregular outline. A minority of the lesions were obviously ringed, by reason partly of the fading colour and partly of the subsidence of congestion of the central parts. The majority, however, faded throughout, leaving slight desquamation or roughness, more conspicuous in certain incidences of the light, and some pigmentation, reminding one strongly of certain phases of tinea versicolor. The scaling was very constant and characteristic, for, though far more delicate than that of psoriasis, it instantly attracted notice. The eruption gradually died away in a month after I first saw it.

This case is a fair example of the rest, which I will not occupy space here in detailing. I have never been fortunate enough to observe the very earliest crops of eruption, but the histories I have obtained go to show that the macules may evolve primarily on the limbs or trunk, that it bursts out in profusion and pretty acutely, and is continued irregularly in a lessening degree for several weeks. I cannot say I have noticed with Gibert that it always commences on the chest and fades in the older parts *pari passu* with its extension elsewhere. The eruption has its chief centre of incidence on the upper part of the trunk and upper arms. Each macule commences as a rosy, very faintly raised, congested macule, the size of a pin's head or lentil, and extends to that of a finger nail, scanty fine adherent scales soon forming, and a considerable number of lesions becoming ringed. The bright colour fades and the macule gets to look like roughened discoloured spots which often bear, especially when confluent, a close resemblance to tinea versicolor. Each macule appears to last for several weeks and leaves behind on its disappearance some roughness and pigmentation. I have never observed any febrile excitement nor constitutional symptoms of moment, although the subjects were pallid.

In conclusion, I must add one word on the diagnosis. To the eye it is not such a bold eruption as psoriasis, nor are the scales so thick, prominent and silvery, nor is the distribution similar, though it is well to remark that we sometimes see an acute general evolution of psoriasis, in which the eruption is small, and far less prominent and scaly than in the usual run of cases. Then it is not a parasitic disease, at least no one has yet discovered a fungus. The affection to which it approaches closest is roseola annulata. It is certainly an eruption of the roseolous type, but quite distinct in aspect and course from the varieties of ephemeral roseola described and figured by Willan and his followers and well known to us. It is often strongly suggestive of the acquired roseolous syphilide, a point not referred to by authors, and a real difficulty might easily occur where corroborative signs of syphilis were not present, as I had the opportunity of observing in a case of either disease which simultaneously presented. The roseolous syphilide, it is well known, may be ringed, and I would refer to the coloured illustration in the *Clinique Photographique* (Hardy and Montméja) of the thighs and trunk of a patient covered with regularly circumscribed, rosy circles, with a yellowish tint, one to three centimetres in diameter. Such an eruption, the authors say, may last two, three, or four months, and relapse six, ten, or fifteen months after the initial lesion. Fournier's observations also on the very tardy circinate roseolar syphilide are very interesting.

SOME REMARKS ON THE

TREATMENT OF DEFORMITIES OF THE NOSE FOLLOWING INJURY.

BY W. J. WALSHAM, F.R.C.S.,

ASSISTANT SURGEON TO AND SURGEON IN CHARGE OF THE ORTHOPÆDIC DEPARTMENT AT ST. BARTHOLOMEW'S HOSPITAL.

DURING the last few years I have had a considerable number of cases of deformities of the nose due to injury under my care; and as the treatment of such deformities is but lightly touched upon in works on surgery, it may be interesting to some to learn the result of my experience. It is not my intention here to speak of recent injuries of the nose, as the deformities with which I have had more especially to deal have been the result of injuries received months or even years previously. For convenience of treatment they may be divided into those affecting, first, the lateral cartilages and, second, the nasal bones.

1. *The cartilages.*—These may be variously bent or twisted to one or other side, or they may be depressed at the spot where they join the nasal bones, giving the nose in this instance a sunken appearance. In the former case the septum nasi (the central column of support) will as far as I know be always found deflected in a direction opposite to that of the bent lateral cartilage, blocking up more or less completely the corresponding nostril. In the latter case—i.e., when the cartilages are depressed, the septum may not only be deflected, but also, as is unfortunately too often the case, fractured with lateral displacement of the fragments, or else dislocated from the maxillary crest. In addition to the deformity, therefore, there will exist the usual train of symptoms accompanying nasal stenosis from other causes—i.e., a sensation of stuffiness in one or both nostrils, a nasal tone of voice, &c. In neither class of cases will either operative or mechanical treatment alone suffice. The septum must be straightened, and the lateral cartilages at the same time be forced into position, and there retained by mechanical apparatus till the septum has had time to consolidate. For

Digitized by Google

retaining the septum in position, in my earlier cases I used Adams' retentive apparatus, modified so as not to injure the columnella. More recently I have had an instrument made of vulcanite, which, however, is open to the objection that the vulcanite is apt to become softened by the heat of the nose, and lose its shape and retaining powers. The advantages of the softer vulcanite may be obtained by having the blades of a steel instrument coated with this material. For solid ivory plugs I have now substituted hollow plugs of vulcanite, which can be worn with greater comfort, as they allow the patient to breathe through them. Many forms of retentive apparatus for holding the lateral cartilages in position were used before I found one which fulfilled all the indications. At first the ordinary nose-truss, which is fastened to the forehead by a band round the head, was tried. This, however, proved of little service, inasmuch as it is liable to shift, and thus give no fixed point to work from. The same objection holds to the spectacle method of fixing the truss. At length this difficulty was overcome by having a mask accurately moulded to the face. A plaster-of-Paris cast is first taken of the face, and in this the leather for the mask is moulded, apertures being left for the mouth, eyes, and nose itself. The mask when thoroughly dry is lined with soft chamois leather, and fits accurately to the irregularities of the face, so that no movement can take place. It is secured by suitably arranged straps around the head. Having thus obtained a fixed point to work from in the mask, it is easy to bring pressure to bear upon the nose in any direction required by means of suitable screws, springs, &c., attached to the mask. The accompanying woodcut is an illustration of a mask made

for me by Messrs. Arnold for a gentleman with very marked deformity of the nose resulting from a bicycle accident. The nose was forcibly straightened and then maintained in position by means of the screw-apparatus shown in the woodcut. It consists of two small, well-padded steel plates shaped to the contour of the nose, and attached by a universal joint to a screw through a small upright fixed at a proper angle to the mask just external to the aperture for the nose. A slight modification is of course required to suit each individual case. If the patient has the leisure, the mask had better be at first worn night and day. In slight cases it need only be worn at night, especially if a plug be kept in the nostril during the day on the side towards which the septum was bent. The plug, if properly applied, is hardly visible and causes a minimum of inconvenience. Messrs. Arnold are now making for me plugs of a flesh colour.

When one or both cartilages have been separated from the nasal bones and depressed, it is much more difficult to overcome the deformity. Indeed, whether it can be overcome or not will then depend upon the condition of the septum nasi. If it be merely bent, it will often be found that on straightening it the depressed cartilage will be raised along with it into position; but if it be fractured or dislocated, it will be difficult, if not impossible, to replace and retain in position the displaced fragments, and hence the necessity to provide a natural support for the depressed lateral cartilages. Even when the septum has been only bent, and not fractured or dislocated, it is not always easy to keep the reposited cartilages in place. They may be readily restored to their natural position by the use of suitable levers and forceps; but after a few days, when the swelling due to manipulation subsides, they will often again sink to their former faulty position. As long as the patient keeps his bed they may be retained in place by making extension on the nose by strips of strapping fixed stirrup-wise on either side of the nose, and then attached through a cord to a weight working over a pulley at the foot of the bed. The objections to this, however, are obvious, and similar ends can be obtained by an apparatus in which the extension is made from the forehead—or better, from the frontal part of the mask. Another method of maintaining the cartilages in position is by levers attached to the mask and introduced into the nostrils—a method, I confess, somewhat objectionable on the score of the pain and irritation which a foreign body gives rise to in this part of the nose, and which can only be overcome by patience and frequent introductions of the levers for short intervals at a time until the mucous membrane becomes accustomed to the irritation. Great care must also be taken that only the gentlest pressure is made, otherwise there is danger of ulceration.

In many of the cases of depression of the cartilages with fracture and displacement of the septum, do what we will but little improvement of the deformity can be obtained; but we should not forget that even here the removal of the displaced fragment and consequent freeing of the obstructed nostril, though it may not much improve the appearance, will give great comfort and relief.

2. *The nasal bones.* — These, like the cartilages, may be merely bent to one or other side; or they may be variously fractured and depressed, often presenting from the sinking in of the fragments and heaping up of callus much deformity. A full account of their treatment space does not permit me to give here. I would only remark on the comparative use with which, even after many years, laterally displaced bones may be forced into position. Unlike the cartilages when once rectified, retentive apparatus to keep them straight is not generally necessary. All that is then usually required being to keep the septum in position by one of the methods that have already been described.

Weymouth-street, W.

ON SOME POINTS IN THE ETIOLOGY OF PNEUMONIA AND BRONCHITIS.

By JOHN WARD, M.D.,
LATE MEDICAL OFFICER OF HEALTH IN WEST CUMBERLAND.

NIEMEYER says, the exciting causes of pneumonia are generally obscure, but that at times it becomes of frequent occurrence, together with other acute inflammatory disorders, attacking their victims without any obvious provocative, through the operation of unknown atmospheric and telluric influences. We particularly observe the epidemic occurrence of pneumonia in severe and protracted winters, during the prevalence of north-east winds, yet sometimes it arises under conditions the very reverse. The statistical statements as to the greater frequency of pneumonia in northerly and elevated localities have of late been regarded as untrustworthy. With regard to the influence of cold, it is difficult to decide in individual instances whether the attack has been preceded by an exposure to cold more severe than that to which the patient has repeatedly exposed himself with impunity. Opinions, therefore, are divided as to the effect of cold in producing pneumonia. Its secondary forms, he says, occur under the influence of an acute dyscrasia, just as catarrh, as we have learned, attacks the air-passages in measles, exanthematic typhus, &c.; and whilst full-blooded, vigorous subjects are not exempt, yet feeble and broken-down subjects, convalescents from grave diseases, and those who have repeatedly suffered, are, perhaps, more liable to be attacked; and that it often complicates diseases which have already effected an impoverishment of the blood with emaciation and constitutional exhaustion. The same author, when speaking of the etiology of *catarrhal* pneumonia, reminds us that in many cases it arises solely through extension of the morbid process from the bronchial mucous membrane into the air vesicles; that the disease is most commonly observed as a companion of measles and of whooping-cough, assigning as a reason of this that capillary bronchitis occurs much more frequently in the course of these complaints than in healthy children. Causes of catarrhal pneumonia other than those from which capillary bronchitis and collapse of the lung originate are unknown. Again, speaking of the causes of hyperæmia and

Digitized by Google

catarrh of the air passages and bronchial mucous membrane, he says that in very many cases the exciting causes of catarrh are unknown; hence we have recourse to hypothetical statements, such as "an increased susceptibility of the skin to change of temperature," "an augmented vulnerability of the mucous membrane," because we have no other explanation at hand. Whilst admitting the presence of certain predisposing conditions, such as the period of dentition in children, and noticing the frequency with which the symptoms are increased as age creeps on, he remarks, very appositely, that "this predisposition probably depends on the feebler capacity for withstanding noxious influences," and, more noticeably, that "the liability to this affection is less among those who inure themselves to exposure."

The opportunity afforded for the careful investigation of the physical surroundings of many fatal cases of pneumonia and bronchitis, during a limited period of office in the Public Health Service, has forcibly impressed me with the truthfulness of these statements of the learned Professor at Tübingen; and I have been accordingly led to trace a seeming correspondence with defective renewal of the air within, during the night especially, and the fatality from bronchitis. Nay, even as if, given the constitutional vigour of the patient and the amount of departure from the health standard of air-supply, results might almost permit of calculation, with some degree of accuracy, especially if other depressing influences could have been estimated. Not less worthy of note is the statement of the same author, amid the obscurity involving the etiology of pneumonia, which, I doubt not, he would admit as alike applicable to both diseases under consideration, touching those noxious influences which, from their enfeebling effect, diminish the resisting power of the system against the attacks of disease.

Calling to mind how frequently this malady occurs during the progress of certain zymotic affections, and remembering how often this class of diseases is associated with a filth-contaminated atmosphere, we might be led even to infer a somewhat similar association of assignable causes; and, indeed, the results of observation would seem to give substantiality to the deduction. My observations are herein confined to an urban and rural district, in the north-west of England, where, moreover, there is a heavy rainfall, and where the houses, generally, are of a more substantial character than the brick structures of the Midlands; and, also, where the dense nature of the building material permits of but little interchange of air through its pores. Many of the houses are old-fashioned in style, containing bedrooms, cul-de-sac fashion, with door and window at one end, and not infrequently having no fireplace and chimney flue which would serve for ventilation. The urban districts, possessing the advantages of general sewerage, are nevertheless exposed to the prejudicial arrangements of waterclosets, with their unventilated drain-sections communicating therewith, placed within or immediately contiguous to the cottages, the atmosphere of which, from their smaller size, was proportionately the more polluted thereby, especially where the house sections were subject to deposit, as is unfortunately the case so frequently; a defect, by-the-bye, which I think might be largely avoided by increasing the distance of the open channel, which should intervene between the end of the discharge-pipe and the sewer inlet, so as to favour the deposit of greasy sediment on the surface, where it might be easily removed; not to speak of the advantage ensured by keeping the sewer a greater distance from the house-foundation, and thereby obviating the danger of fouling the air within.

The following examples are selected from a large number of fatal cases of disease, of a varied character, which I had learned would be likely amply to repay the trouble of investigation, if but suggested improvements could be effected, occurring during the last year of my tenure of office, the year 1880, the winter months of which year were very severe, and the cold of which would have tended rather to intensify sanitary, structural defects by favouring a determination towards the warmer air within doors from adjacent sewers, &c., as well as to favour the generally accepted idea of the increase of such diseases with the occurrence of cold. They are taken from notes which I made on the spot at the time of inspection, the cause of death being put down as reported on the duplicate certificate furnished by the local registrars; and it may be supposed their enumeration and careful study will have a tendency to convince the most sceptical that insanitary influences have a much wider and further extended causative relation to disease than is generally acknowledged, and, consequently, it is hoped, tend to strengthen the admission of the necessity of taking into consideration the surroundings of the patient more frequently by the medical attendant, as alike widening the field of etiological inquiry, according to therapeutical agents, their truer value, and more particularly affecting prognosis, ever bearing in mind the oft-repeated injunctions of the above-mentioned erudite professor, to seek to "fulfil the causal indications," not unmindful of the aphorism *sublata causâ tollit effectus*; our aim being ever to secure, as far as possible, the physical prerequisites of health, not merely wholesome food and good water but a pure house-atmosphere to breathe. Chemists have been able to detect comparatively little chemical difference between the amount of oxygen in the atmosphere of our towns and in pure mountain air; but far otherwise is it when the foul air within our tenements is subjected to their severer tests; and can the physiologist be slow to recognise the effect on the delicate human organism of being continuously subject to its direful operation? The earnest prosecution of sanitary work, it is greatly to be regretted, does not meet with the encouragement on the part of the several sanitary authorities which its importance demands; and already there is the danger, but too apparent, as Dr. B. W. Richardson has observed,[1] "of a most enlightened and useful service degenerating into that of the office of mere clerks or chroniclers of disease; suggestors of placebos; gentlemen of education engaged by money for incomplete service."

When we have boards of health impressed with the greatness of their beneficent duty, advised and served by men alike imbued with its importance, who are not, as now, subject to the fickle caprice of their employers, and treated too often as abject menials, we may hope to attack the strongholds of disease, one after another, with method and success, and win for the Public Health Service the laurels which a timorous administration has tended to keep back. Out of a population of about 50,000, I have notes of some sixty fatal cases of pneumonia and bronchitis, for the year which is at my disposal, some of the cases being complicated with other diseases, in all of which I observed tangible sanitary defects, which I have attempted to detail as follows:—

R. D——, aged forty-three; carter; pneumonia; cottage, the bedroom of which forms a cul-de-sac and has no fire place, adjoins the fever wards of the workhouse, the sanitary arrangements of which are defective, the sewer sections and soil pipes of the waterclosets in connexion therewith being unventilated. J. D——, aged fifty-six; pneumonia; drain, into which eaves spouting enters, close to back door, out of repair, emitting foul odour; watercloset, the sewer section leading to which is unventilated, immediately adjoins outer kitchen. J. G. C——, aged nineteen; stoker; congestion of lungs; sewer section, under the property, connected with imperfectly flushed main; chimney flue of bedroom papered over. W. T——, aged thirty-two; carter; pneumonia; drain from yard gully and watercloset placed very near back door, repeatedly blocked. The wife of deseased said, "He complained only on the Saturday before he was laid up that the smell was awful; he had suffered from his stomach ever since coming to reside at the house"; odour upstairs very offensive, when the air is not in free motion. J. H——, aged forty-one years; blacksmith; alcoholic intemperance; pneumonia; cottage or dwelling over shoeing shed; defective ventilation of bedrooms. T. K——, aged twenty-six years; steelworker; pneumonia; house damp and imperfectly ventilated. J. C. M——, aged forty-two years; nurseryman; erysipelas; pneumonia; slopstone waste-pipe in direct contact with town sewer; bedrooms small, some without fireplaces. J. G——, aged twenty-nine years; black-lead pencil maker; pneumonia; house overcrowded and damp; six slept in one small bedroom, the chimney flue of which was stopped up. W. P——, aged eighteen years; black-lead pencil maker; empyema two years and a half, albuminuria one year, dropsy six months; deceased occupied a small tenement at the rear of a block, the diminutive bedroom of which was placed over an offensive watercloset, the drain section of which was unventilated—a sad place. J. W——, aged forty-five years; painter; pneumonia; slopstone waste-pipe communicates with sewer; watercloset, with unventilated drain section, adjoins the dwelling. M. N. P——, aged nine months; whooping-cough; pneumonia; house large and commodious, but built by the side of a large stable, where a number

[1] Journal of the Society of Arts, March 28th, 1884.

Digitized by Google

of houses are kept; the slopstone waste-pipe communicates directly with the sewer; watercloset with offensive "container" apparatus, and unventilated soil-fall-pipe in the centre of the house. The children, the offspring of healthy parents, had have suffered much in health, which greatly improved on their removal to a healthy house. S. D——, aged nine months; pneumonia; the drain passes under the house. Some time previously scarlet fever spread through the village from this house as a centre. J. B——, aged seventeen years; scarlet fever, pneumonia; the middenstead of a neighbouring farmer placed almost close to the dwelling. W. B——, aged three years; pneumonia; the village sewer courses under one corner of the cottage; bed placed in recess of small room. J. W. S——, aged three years; pneumonia; bed placed in corner of badly ventilated room; a cow-house adjoins the end of the row of cottages of which this forms a part. M. J. G——, aged thirty-six years, innkeeper; delirium tremens; drain passes under the premises, and filthy stable immediately adjacent to cottage, which intervenes; husband of deceased died some months previously from pneumonia. J. A. F——, aged fifteen months, son of a greengrocer; pneumonia; offensive drain adjacent to dwelling; bedroom without fireplace; quantity of decomposing onions in the house. A. B——, aged fifty-eight years, death not registered as to cause; on inquiry judged to be pneumonia; deceased, a farm servant, lived at the time of his death at a farmhouse which adjoined an offensive stable, close to the loft of which the bedroom in which he used to sleep was situated, the chimney flue of the same being stopped up. T. B——, aged sixty-five years; double pneumonia; watercloset with unventilated sewer section underneath living room. J. W——, aged eight years; scarlet fever, pneumonia; three slept in small cul-de-sac room, the air of which appeared stagnant and oppressive; pig kept within a few yards of the dwelling. R. B——, aged forty-three years, bookseller; heart disease, pneumonia; house with "container" watercloset apparatus, the soil-pipe being unventilated; the health of the deceased impaired by alcoholic excess. J. S——, aged two years; pneumonia; cottage has only one bedroom, which is destitute of fireplace or other means of permanent ventilation. H. H. Y——, aged one year; congestion of the lungs; house has "container" watercloset, with unventilated soil-fall-pipe. J. F. O——, aged one year and nine months; measles, pneumonia; old barn adjoins the house, in which a pig and fowls are kept; bedroom without fireplace or other suitable provision for permanent ventilation. M. M'O——, aged thirty-eight; labourer; pneumonia; three slept in a small bedroom which had no fireplace or other suitable provision for permanent ventilation. J. R——, aged one year and nine months; measles, pneumonia; six slept in a small bedroom without fireplace or other provision for continuous renewal of the air. W. E——, aged four; measles, pneumonia; slept with parents in cul-de-sac room, the chimney flue of which was stopped up. S. B——, aged fifty-three; broncho-pneumonia; house permeated with offensive odour from filthy stable, which immediately adjoins, and badly ventilated. J. T——, aged thirty-four; pneumonia; back-to-back house; cul-de-sac bedroom; chimney flue papered over. J. A. R——, aged nine months; congestion of lungs; no fireplace or permanent ventilation in bedroom. A. B——, aged thirty-nine; childbirth twelve days ago; broncho-pneumonia seven days; back-to-back house, built up against soil; cellar of same damp; bedrooms badly ventilated. M. J. L——, aged three years; pneumonia; back-to-back house; child slept between the parents, breathing the devitalised breath of both. E. J. H——, aged two years; morbilli, broncho-pneumonia; slept with parents in close corner of room. J. L——, aged sixty-one; broncho-pneumonia; slop-stone waste-pipe in direct contact with sewer; stench-trap at inlet out of repair. J. G. K——, aged two years and a half; pneumonia, phthisis; slept between parents; odour of small bedroom, the door of which was closed when occupied and chimney flue stopped up, offensive. E. T——, aged four years; pneumonia; bedroom insufficiently ventilated, forming cul-de-sac. H. J——, aged nine years; pneumonia and meningitis; house damp from soil at back and gable, and otherwise insanitary; an old pigstye adjoins, now used as a duck-coop. S. A. J——, aged twenty-two months; pneumonia, convulsions; no fireplace in bedroom. A. G——, aged fifty-nine years; pleuro-bronchitis; drain courses under property. R. A. D——, aged one year; broncho-pneumonia; watercloset, with unventilated sewer section, immediately adjacent to dwelling; unventilated drain passes up enclosed passage, contiguous. J. H——, aged three years; measles, broncho-pneumonia; watercloset, with unventilated sewer section, within the premises; drain at back, defective flush and obstructed. T. B. J——, aged eleven months; bronchitis; slept with parents in badly ventilated room, the chimney flue of which was stopped up. J. N——, aged one year; bronchitis; bedroom badly ventilated, chimney flue of same stopped up. F. L——, aged eight months; bronchitis; bedroom badly ventilated, forming cul-de-sac. T. B——, aged two months; capillary bronchitis; cottage adjoins house, at the further end of which is a stable; bed placed in close corner of room, the chimney flue of which is papered over. L. H——, aged eleven months; bronchitis; seven occupy one room; deceased slept with parents in bed placed in close corner. S. M. K——, aged eleven months; bronchitis; bedroom forms cul-de-sac, badly ventilated. J. S——, aged three months; bronchitis; house new, damp soil. M. A. R——, aged forty-seven years; bronchitis; watercloset, with "container" apparatus and D-trap, and unventilated soil-pipe, in centre of house; slopstone waste-pipe communicates direct with sewer; offensive odour at time of visit, the bell-trap being out of place on slopstone. J. M. C——, aged two years; bronchitis; slept with parents in cul-de-sac bedroom. A. G——, aged thirteen months; congestion of lungs, convulsions; bedroom close, chimney flue stopped up. J. B——, aged fifty-nine; pneumonia; watercloset, with unventilated sewer section, immediately adjacent to dwelling; bedrooms badly ventilated. E. S——, aged forty-six; bronchitis; bedroom, which has no fireplace, immediately over undrained stable and byre. B. J——, aged one year; bronchitis; drain courses up enclosed passage; watercloset, with unventilated sewer section, directly attached to dwelling. M. McM——, aged eight months; back-to-back house. L. B——, aged eighteen months; bronchitis; watercloset, with unventilated sewer section, adjoins back kitchen. H. J. F——, aged six months; bronchitis; overcrowding; five slept in one small room, the chimney flue of which was stopped up.

From this crude and yet momentous summary, which might have been indefinitely increased by bringing the experience of other years before the reader, will, I think, be apparent the immense importance of securing for all an in-door atmosphere uncontaminated with animal filth emanations; and, in fact, that there is greater danger in a deficiency of ventilation than in a moderate excess. It would be easy to show the relation of such a polluted atmosphere to the etiology of other acute diseases, such as peritonitis, &c., as I have endeavoured to trace with respect to inflammation of the brain (see THE LANCET of Jan. 19th, 1884); whilst more chronic so-called scrofulous and other diseases of denser structures might be shown to appear to have a more than fancied association with such causes. But there are always risks connected with hasty generalisations which the cautious would not expose themselves to the odium of, and which I should have felt backward to undertake were it not that all experience, technical and common-sense, alike points to the dangers which it has thus been my purpose to bring into more prominent relief.

Fully conscious of the frequency with which deposit of an offensive nature is apt to occur in the house sections of sewers, and of the evils which appear to be directly traceable to the placing of waterclosets, with their usually unventilated sewer connexions, in immediate contact with the dwelling-house—thereby favouring the direct determination towards the warmer air within, especially in cold weather, when the surface of the ground is sealed with frost—I have, when in office, urged my boards to enforce the placing of these structures when on the ground floor, and consequently presenting difficulties connected with the efficient ventilation of the sewer section in communication therewith, as in cottage houses, in a position *detached from the dwelling*, or from any outer structure immediately attached thereto.

BEQUESTS.—By the will of the late Mr. Edwin Cox £500 is bequeathed to each of the following institutions: the Royal Free Hospital, Earlswood Idiot Asylum, the Deaf and Dumb Asylum, Old Kent-road, the City of London Truss Society, the National Benovolent Institution, the Hospital for Consumption and Diseases of the Chest at Brompton, the Cancer Hospital, Middlesex Hospital, Westminster Hospital, Charing-cross Hospital, and St. Mary's Hospital.

A NEW PLAN OF OPERATING UPON MENINGOCELE.

BY NOBLE SMITH, F.R.C.S. EDIN.,
SURGEON TO THE ALL SAINTS CHILDREN'S HOSPITAL, AND SURGEON TO THE ORTHOPÆDIC DEPARTMENT OF THE FARRINGDON DISPENSARY.

CONGENITAL hernia of the membranes of the brain has hitherto been a very unsatisfactory deformity to deal with. Almost every child so affected has died early, whether subjected to operative treatment or not. Injection of iodine into the sac has been the least unsuccessful operation tried, and Dr. Morton's iodo-glycerine fluid is doubtless the best form in which it can be used. The risk, however—one may almost say the certainty,—of any fluid thus used passing into the cavity of the skull is a serious objection to this means of treatment; and were it not for the fatal nature of the affection when left to itself, surgeons would probably seldom venture to operate upon the subjects of it at all. I have devised a plan by which the risk of the injected fluid passing beyond the sac is reduced to a minimum, and I will now describe the only case upon which I have yet operated in this manner.

C. H.——, aged fourteen days, was sent to me by Dr. Fancourt Barnes from the British Lying-in Hospital in January of the present year. Fig. 1 shows the size of the tumour. The sac was formed of healthy skin, and could be emptied by pressing its fluid contents into the cavity of the skull, a proceeding which caused the infant to cry. I exhibited the child at a meeting of the Medical Society on February 11th. With regard to the treatment, I tried in the first place the effect of pressure. I made a cast of the tumour, upon which was moulded a piece of gutta-percha. From February 1st the pressure was gradually increased until March 31st, when, finding no improvement had taken place, I resorted to the following operation. The sac was emptied by pressure and its two sides held together between my finger and thumb. My intention was not to inject into the cavity of the sac, from which the fluid would have free access into the ventricles of the brain, but if possible to inject into the wall of the sac close to the lining membrane. I used a hypodermic injection syringe and pierced the sac as it was held between my finger and thumb, directing the point *just to one side of the median line*. The latter line would, of course, represent the cavity of the sac which for the time being was obliterated. I must have penetrated very near to this cavity, but did not pierce it, for upon injecting the fluid there was considerable resistance to its entry, although I had ceased to hold the sac and the latter had refilled. If the needle had penetrated the sac, the resistance would have been certainly slight, and the after-effects might have been severe. I could only inject a few minims of iodo-glycerine (about eight); the child cried, and continued to evince symptoms of discomfort for the next two hours, when he fell asleep, and subsequently awoke seeming to be quite comfortable, and remaining so. Upon April 15th I injected the tumour again in the same way. On April 23rd the child's general health was good, the tumour felt firm, as if it was consolidating; I therefore ventured to pierce it to the centre with the needle and injected more iodo-glycerine. Upon May 1st I found that no bad symptoms had followed the last operation, the tumour was feeling firmer. I repeated the injection on May 14th, and again on June 15th; upon the last occasion I left at least twenty minims in the centre of the tumour, which was a larger quantity than I had hitherto used. On July 14th the child was quite well, the tumour was contracted to a flattened corrugated mass of skin, as shown in Fig. 2, and the case cured.

FIG. 1.

Before operation. The fluid contents of the sac could be pressed into the cavity of the skull. (Exhibited at a meeting of the Medical Society, Feb. 11th, 1884).

FIG. 2.

Five months after first operation (July, 1884). The remains of the tumour being hard cicatricial substance completely closing the opening into the skull.

By injecting into the walls of the sac we not only prevent the iodine from entering the cavity of the skull, but we also attack more directly the part which we wish to influence—namely, the sac, which we wish to contract.

Queen Anne-street, W.

BICYCLE RIDING AND PERINEAL PRESSURE, THEIR EFFECT ON THE YOUNG.

BY S. A. K. STRAHAN, M.D.,
ASSISTANT MEDICAL SUPERINTENDENT, COUNTY ASYLUM, NORTHAMPTON.

CYCLING is doubtless a very healthy and pleasant mode of exercise when used in moderation, but now that tens of thousands of our boys ride bicycles daily, and "get up records" of thousands of miles in the year, it may not be out of place to point out some alarming evils which are likely to arise from this abuse of an otherwise healthy pastime. Some time ago it was pointed out that obscure nervous complaints would probably be developed by the continual jarring—the succession of shocks conveyed to the spinal column in bicycle riding; and this, I believe, has proved correct in many instances, notwithstanding "Arab springs," and "rubber cushioned" machines. But it is to something much more serious than this that I would now call attention: it is to the amount of pressure brought to bear upon the perineum in growing boys, affecting directly the prostate, the muscles of the bulb, &c., and indirectly the whole generative system.

The bicycle saddle is now reduced to the smallest possible limit. It is just wide enough at its posterior part to cover the ischial tuberosities, and it tapers off quickly to a long, narrow horn in front, upon which the perineum rests. Let us consider the position of the body and limbs when the rider is mounted, and we can then appreciate the amount of body weight which must be thrown upon the perineum. In bicycle riding the legs are, when extended, vertical, and the pelvis is flexed upon the thighs or rolled forward. This rolling forward of the pelvis is slight in easy riding, and very marked in fast riding and hill climbing. Now, when the body and pelvis are bent forward, the ischial tuberosities are raised from the saddle, and the whole weight of the body, save what is transmitted to the pedal by the then extending leg, is thrown upon the perineum. It is not much of the body's weight that is conveyed to the pedals. In easy riding on the level the weight of the limb from the hip down is sufficient to move the machine, and in hard riding the extra pressure is gained not so much by throwing the body's weight upon the pedals as by pulling upward on the handle-bar, and so further increasing the pressure of the body upon the saddle. But even admitting that the pressure upon the perineum be only a few pounds, I hold that it must be injurious in the extreme, for were the pressure *nil* when riding upon a perfectly plane surface, it must at times be considerable when the machine is ridden over an unequal surface such as is afforded by our best country roads. Let those who talk of "the beautiful gliding motion of the bicycle" try to play a game of billiards after a ride of twenty miles, and then explain where all their "shakiness" comes from if their motion has been that of the skater. Now, this pressure on the perineum, whether it be continuous and increased at every jolt, or whether it be made up of jolts alone and be *nil* in the almost imperceptible and irregular intervals must be injurious, more especially to growing boys. It must cause irritation and congestion of the prostate and surrounding parts, tend to exhaust and atrophy the delicate muscles of the perineum, and also call attention to the organs of generation, and so lead to a great increase in masturbation in the timid, to early sexual indulgence in the more venturous, and ultimately to early impotence in both.

We all know that among the Tartars horse-riding causes complete impotence in many of their strongest and most daring men, with wasting of the testes, dropping of the beard,

Digitized by Google

and change in the pitch of the voice; and we also know that the introduction of the horse into the western world had quite as much or more to do with the extermination of the red man than had the almost simultaneous introduction of the European. In a southern tribe of Indians—that is, a horse-riding tribe—it is a marvel to find a squaw with more than two or three children, though they—both men and women—marry young. Impotence is said to be common amongst them at thirty. The "disease of the Scythians" and its causes are sufficiently notorious.

If, then, these sad results are the outcome of immoderate equitation where there are an extensive seat and a stable foot rest, and where the adductor muscles of the thighs are used, what are we to look for, where our boys of ten and upwards spend the greater part of their own time riding bicycles, and get over thousands of miles in the year, perched upon a saddle no bigger than the hand which conveys every jolt of the machine to the body; where the jolts are ten times more numerous than those experienced by the equestrian and, occurring without any approach to rhythm, are conveyed unexpectedly to the person?

Some time ago Dr. B. W. Richardson when advocating cycling as a healthy exercise said, if I remember rightly, "that what made cycling so healthful an exercise was that in it you enjoyed all the muscular motion experienced in walking with this advantage, that the bodily weight was taken off the feet and legs." This, of course, would be an advantage if the bodily weight were better bestowed than it naturally is upon the feet; but as it is on the bicycle the transference of weight from the feet to the perineum cannot but be for the worse.

It must be understood that what is said in this article applies particularly to growing boys, who generally straddle the largest machine their length of leg permits, and so greatly increase the liability to perineal pressure. What cycling—for the saddle with the long, up-turned horn, is now almost universally used for the tricycle too—will do towards the advance of those prostatic affections which so often render the closing years of life miserable, time alone will tell.

Barry Wood, near Northampton.

TREATMENT OF

THE HABIT OF INJECTING MORPHIA BY SUDDENLY DISCONTINUING THE DRUG.

BY J. ST. THOMAS CLARKE, M.B. LOND., F.R.C.S. ENG.

THE following case is one of several similarly treated at Mrs. Theobald's Institution, Leicester.

A lady, aged twenty-nine, the wife of a medical man, was admitted to the above institution on March 25th, 1884. She was in the habit of injecting herself with morphia subcutaneously three or four times a day, always in the arms, and injecting three or four syringefuls at a time, each syringeful containing about twenty minims of a solution of acetate of morphia of the reported strength of twenty-five grains to the so-called ounce bottle of water. The bottle I found held nearly nine drachms and a half of fluid. The solution so made contained, therefore, quite two grains and a half in the drachm, which made up her usual dose, though at times this was exceeded; and probably in the day she would thus absorb from eight to ten grains of morphia—perhaps more. The first dose was usually in the morning, before or after breakfast, the second one later on in the morning or afternoon, and the last about 11 at night. The habit was of nine years' duration, and had not been associated, as is frequently the case, with a fondness for intoxicating drinks. The drug was first used hypodermically for gastrodynia and sickness during pregnancy, the quantity being increased gradually the last few years. The patient was a tall stout woman, five feet eight inches in height, weighing about thirteen stones, with a somewhat leaden complexion. The pupils were rather contracted but not unduly so. Her appetite was fairly good. She had had two children, the last in 1878. The catamenia were regular. She had had diarrhœa at times. Her arms were bulbous and pitted, with red indolent swellings here and there from irritation or suppuration following the injections, and altogether they presented an unseemly sight from shoulder to wrist, with blue and white indented scars, the results of former abscesses. She expressed herself anxious to get rid of her slavery, and voluntarily handed me her apparatus and solution on March 25th. She kept up bravely till the evening, when she began to feel the want of the morphia, and passed a restless night with gradual development of intense gastric pain. The treatment followed during the progress of the case included resting the stomach, the administration of bicarbonate of soda and bromide of potassium, effervescing medicines with prussic acid, chloroform, and opium liniment to the pit of the stomach, then bismuth, bicarbonate of soda, prussic acid with barley-water, arrowroot, gruel, &c., and skilled nursing. Ice was not given, as it was objected to. Her condition the second day was one of great restlessness, tossing about the bed, incessant vomiting of green bile, great gastric pain, no sleep, bowels free, with an evening temperature of 100·5°. On the 27th (the third day of treatment) the general symptoms and temperature were the same, though scarcely so marked, but the pupils were dilating. On the 28th they were much the same, with a temperature of 101°. The vomiting of green bile was still very obstinate, but the patient stated that she had had about three hours' sleep during the preceding night. She also looked better, and had become cheerful and much less restless. On the 29th she stated that she was sick only once during the preceding night, and was then having simply barley-water in small doses. On the 30th she was progressing favourably; the sickness had ceased, and the patient experienced a feeling of hunger. Chicken broth, milk and barley-water, and tapioca pudding were ordered. On the 31st she was still progressing; the slop diet had agreed with the patient; sleep was obtained, but only half an hour at a time. On April 1st the temperature was 100°, but she was doing remarkably well, and sat up for a while. On the 2nd the patient was sick once, but she sat up longer. On the 3rd she was allowed to go downstairs to dinner. On the 5th she was gaining strength rapidly. The further progress of the case was onwards to complete convalescence and restoration to health.

At the end of June her husband stated that the improvement had been progressive. He says she sleeps all night, has lost the fits of sneezing and slight diarrhœa with which she was troubled after leaving, and the dysmenorrhœa from which she suffered prior to the morphia habit is now much less than before. She is less stout, has never asked for or suggested a return to morphia, and has no special desire for any stimulants. Though advised by us to become a teetotaller, she takes about a pint of ale and half a pint of ginger beer a day, with no bad tendencies so far. She never asks for wines or spirits, and has no mental worry or depression. Her temperament is quite light-hearted, and she is about to make a long sea voyage.

Remarks.—The above case presents some peculiarities, among which the absence of any alcoholic craving and the restriction of the case to chronic morphia poisoning are to be noted. This quality, as observed by her husband, is probably the fact to which may be attributed the rapid and unique completeness of her cure, and is a point of considerable importance. Another point is the success of the abrupt discontinuance of the drug as a method of treatment. Dr. Benjamin Ward Richardson, in the *Asclepiad* of January, 1884, has a very able paper on "Morphia Habitués and their Treatment," and after weighing the evidence in support of three different modes of treatment—viz., (1) the substitution of some other drug, such as chloral, or some alcoholic drink; (2) the abrupt method; and (3) the tapering off plan—insists on the last method, carried out in a systematic form and gradual manner, as being the right and most trustworthy one. From experience of the tapering off plan in several severe cases I am forced to confess my disappointment in it, and a disbelief of its value. I contend that the method of sudden and absolute withdrawal has greater advantages in the end for patient, doctor, and nurse. It is only of late that this plan has become more recognised in the profession in the treatment of delirium tremens and dipsomania; but it is a fact that this plan has been carried out at Mrs. Theobald's Institution for many years with most signal success, and so far I have seen no bad results. In the morphia cases the patient is infinitely more manageable on the sudden withdrawal plan than on the others. I may note that in this case the catamenia had never been checked by the morphia; though I had a case some time ago where they were in abeyance for five years under morphia injections, and the habit being suddenly broken they became re-established, and pregnancy followed.

ETHER AS AN ANÆSTHETIC IN CASES WHERE THERE IS OBSTRUCTIVE DISEASE OF THE LEFT SIDE OF THE HEART.

BY ARTHUR JEFFERSON, M.R.C.S.,
HOUSE-SURGEON, YORK COUNTY HOSPITAL.

UNTIL the following case came under my observation I never thought it necessary to examine the heart before administering ether. In all cases, provided the patient was neither a young child nor an old person, I was in the habit of giving ether without making any further examination than glancing at the chest walls, to see that they were not too rigid, and asking the question, "Have you a cough?" Both these points being settled in the negative, the anæsthetic was given without further delay. Having given the anæsthetic in several cases of regurgitant valvular affection, and having noticed its great stimulating effect in this form of cardiac derangement—so great that in three cases the murmur has been found to disappear under the ether, reappearing gradually as the effects of the drug wore off,—and also in the almost pulseless heart of collapse; the conclusion was somewhat hastily arrived at that the state of the heart did not matter in ether giving. However, last year a male patient, aged fifty-two, was admitted to the hospital under the care of Mr. Jalland, who decided to perform an operation upon him. Accordingly, the man not being emphysematous and not having a cough, the administration of ether was commenced. The patient took the anæsthetic badly, and there was a good deal of struggling, some minutes elapsing before conjunctival insensibility was arrived at. Just at this stage the patient's breathing began to excite attention; it became somewhat hurried and very shallow. The pulse, however, continued regular and strong; in a very few seconds the face commenced to turn blue, and the respiration became so shallow as to be purely laryngeal, no movement of the abdomen or chest-wall being perceptible. The ether was at once discontinued, and artificial respiration commenced. After a few minutes the blueness of the face had disappeared, and the respiration had become fairly normal. As it was important that the operation should be at once performed, the patient was allowed to partially come round, and then, his heart having been stethoscoped and found to be apparently healthy, chloroform was administered. Up to this time, even when he appeared to be on the verge of death from the first anæsthetic, his pulse had remained good, but now, after a couple of minutes of chloroform inhalation, it rapidly failed, becoming irregular. By means of the cold water towel and brandy the patient was brought round and the operation postponed. In the evening of the same day the man's heart was again examined, this time more carefully; there was now found a slight thrill at the apex and a somewhat presystolic murmur in the same situation, which murmur could only be heard over about half a square inch of chest surface. These symptoms evidently indicated mitral stenosis. A week after the patient was again brought into the operating room and kept under the influence of unmixed chloroform for about forty-five minutes, without at any time showing any alarming symptom.

Remarks.—In this case what would appear to have happened is somewhat as follows. The heart, under the influence of the ether, commenced as usual to contract more vigorously, the consequence of this being that while its right side was urging on an increased quantity of blood into the lungs, this same surplus was prevented from escaping thence by reason of the contracted mitral orifice. Hence the lungs became more and more congested; this congestion, added to the peculiar respiratory effects of the ether itself, caused the patient to assume, little by little, the appearance of one about to die of asphyxia. No lung complication being suspected at that time, it was inferred that the patient's condition was caused by some susceptibility of his respiratory centre; it was not thought that chloroform could have any direct influence on this, and therefore the heart being seemingly healthy, this anæsthetic was given. It can easily be imagined that this drug, acting on a diseased heart struggling with still congested lungs, would cause the irregularity of the pulse which ensued. Finally, it was demonstrated in the following week that chloroform could be given, in the absence of the congestion of the lungs, with perfect safety. This case would seem to show that the heart should always be examined before ether is given; and that the giving of this anæsthetic is, at any rate, a very questionable practice in cases where there is obstructive valvular disease on the left side.

WEST LONDON HOSPITAL.

ACUTE TRAUMATIC (?) TETANUS; DEATH ON SEVENTH DAY OF ILLNESS; AUTOPSY; REMARKS.

FOR the following notes we are indebted to Mr. J. P. Glover, house-physician.

J. M——, aged twenty-six, was admitted on August 4th, 1884. He was in his usual health until about four days previously, when he began to suffer from pain in the lower part of the back and between the shoulders. On the following day the pains became worse, especially on movement, and they radiated from the spine round the lower part of the chest and the upper part of the abdomen. Stiffness of the lower jaw followed, and spasmodic contractions of the extensor muscles of the thighs.

On admission his face was pallid and wore an expression of suffering, the skin was hot and perspiring freely. The lower jaw was firmly closed and almost immovable; the speech, except for this, was not affected, and fluids were taken and swallowed without difficulty or resulting spasm. The chest muscles were not much affected, and the diaphragm moved freely. The arms were unaffected, both as regards motion and sensation. The extensor muscles of the thigh, the muscles of the back, and, to a less extent, those of the abdomen, were affected with tonic spasms of momentary duration, and but slight severity, occurring once or twice in a minute. Risus sardonicus was observable during each spasm, but the spine was not noticeably arched. The patient complained of pain in the back and in the affected muscles, especially the thighs, which was worse during the spasms. Turning in bed or movement of the legs was painful, and produced the painful contractions mentioned above. The back was reddened and slightly blistered by the fomentations and turpentine stupes which had been applied before his admission, but there did not appear to be any especially tender spot elicited either by pressure or the hot sponge. There was no priapism, nor loss of sensation or motor power. Urination was normal; bowels confined. The patient was quite sensible, and remained so to the moment of death. The temperature was 101°; pulse 90, quickened with each spasm; heart sounds normal.

No history of wound or injury was given on admission, but he had a small healed-up scratch on the hypothenar eminence of one hand, which was said to have been done by a rusty nail about a fortnight previously. He said he had got wet through a week or so before admission, and thought he might have taken cold.

Aug. 5th.—The patient's condition was substantially unchanged; the spasms, if anything, were less severe. At no time was there any noticeable retraction of the head or approach to opisthotonos. The breathing was more shallow and chiefly diaphragmatic, the chest walls moving but slightly. There was little pain, except during the spasms, which continued to be several to the minute and lasting two or three seconds. At 7 P.M. he was suddenly attacked with a very severe convulsive spasm, engaging all the muscles of the body and arching the body to one side, stopping respiration and apparently the heart's action. For a minute or so he lay motionless and apparently moribund. Breathing, however, returned in short gasps, drawn through the clenched

Digitized by Google

teeth, and respiration became gradually quiet and natural. A second, but not quite so severe, attack occurred an hour later, after which he had a pretty quiet night and some sleep. He could still swallow fluids without difficulty.

6th.—The general symptoms became rather more pronounced during the day. The spasms rather more severe and painful; swallowing became difficult, and excited spasms when attempted. The evening temperature was 102·8°; the pulse 152 (feeble); respiration shallow and diaphragmatic (68). Voluntary power was distinctly impaired, and the patient said he felt weaker all over. Urination was very frequent, but voluntary.

7th.—The patient was in less pain, but evidently weaker. The spasms but slight; temperature 104·8°; skin pallid and perspiring profusely. About noon, without any general spasm, he suddenly turned livid, respiration and the heart's action stopped together, and he was dead in a few seconds. He was quite sensible to the last, and spoke just before the final seizure. The case thus lasted just a week from the onset of definite symptoms, and about a fortnight from the receipt of the scratch on the hand.

The treatment consisted of ice to the head and spine, with an initiatory purge of calomel and jalap, chloral hydrate, and hypodermic injections of morphia.

At the necropsy, made twenty-four hours after death, the brain and spinal cord were carefully examined, but nothing abnormal could be found in either by naked-eye inspection.

Remarks.—This case is considered an interesting one from its departure in many particulars from the ordinary courses of tetanus; indeed, for some time it appeared doubtful whether it might not be one of spinal meningitis. The recurrence throughout the attack of spasms of but little, and scarcely at all increasing, intensity, the two isolated severe convulsive seizures, the free action of the diaphragm, the late appearance of any difficulty of swallowing, and the very slight opisthotonos, combined to render the case an anything but typical one.

CUMBERLAND INFIRMARY, CARLISLE.

PYO-SALPINX; LEAKAGE INTO THE UTERINE CAVITY; ABDOMINAL SECTION; DRAINAGE; RECOVERY.

(Under the care of Dr. LEDIARD.)

ISABELLA C——, aged twenty-seven years, residing at Flimby, came in on April 30th, 1884. She stated she had been married for six years, having a healthy child aged three years. Before and after marriage her periods were irregular and attended with more or less uneasiness; but fifteen months ago she first noticed a thick, yellowish, acrid vaginal discharge, which was offensive and excoriating; at the same time a dull heavy pain was felt in the right iliac region and above the pubes, for which she was treated as an out-patient at the Newcastle Infirmary.

The patient was thin and sallow, and her spirits were much depressed. Careful palpation over the painful area revealed a swelling the size of a small orange about the brim of the pelvis on the right side; there was considerable tenderness on pressure and a sense of elasticity conveyed to the finger. Per vaginam the uterus was rather fixed and pushed over to the left side of the pelvis, whilst high up to the right of the uterus was an elastic swelling which was continuous with the swelling felt through the abdominal wall. The discharge, as it issued from the vulva, was ascertained to be purulent, and when the patient was examined with a speculum a thick tenacious fluid was seen issuing from the os. (The notes unfortunately do not state if it was pus-like.)

On May 24th, the intestines being carefully pressed away from the tumour, Hensley's exploring aspirator was used just above Poupart's ligament, and some thick offensive pus was drawn off.

On the following day the patient was subjected to median abdominal section, with a view to draining or removing the disease. Upon pushing the bowels aside the tumour was with some trouble exposed, lying deeply, and found to occupy the right side and upper portion of the pelvis; adhesions to uterus, intestine, and pelvic brim entirely negatived the idea of removal, accordingly the tumour was incised, and found to possess walls of great thickness, as had been conjectured at the time of aspiration. Some two ounces of stinking pus were sponged away as it oozed out; the incision was then enlarged, and the finger searched the soft interior of the abscess. The abdominal wall was then depressed and stitched firmly to the margins of the sac; a drainage-tube and some wood-wool completed the dressing.

Two days after operation the offensive discharge disappeared from the vagina; the temperature, normal for the first four days, rose on account of some pus shut up by the stitches, and fell when these were cut. The cavity of the tumour was kept constantly drained until obliteration was completed; and the patient left the Infirmary in good health and capital spirits on July 16th, having had a painless "period" since operation.

Remarks by Dr. LEDIARD.—The interest of the case lies very much in the fact that we had to deal with a pyo-salpinx or collection of purulent fluid within the right Fallopian tube, which leaked from time to time into the uterus—a circumstance which has not hitherto been noted in connexion with this disease. Mr. Lawson Tait informs me that he has often expected to find a hydro- or pyo-salpinx communicating with the uterine cavity, but has never done so. I was much struck with the thickness of the walls of the tumour, which would be understated if put at half an inch; and it seems reasonable to suppose that the density of the walls prevented that increase of size in the tumour which might have occurred, thereby forcing open the uterine end of the Fallopian tube and establishing leakage rather than drainage. The question of draining the tumour from the uterine cavity we did not care to entertain, and were fortunate enough, by the recovery of the patient, to be unable to say how far such idea could have been realised. One other point which seems to confirm the diagnosis, and one which may be of diagnostic value in the future, is the statement of the patient that the yellow discharge was mixed with the menstrual fluid.

KASHMIR MISSION HOSPITAL.

DISEASE OF MASTOID CELLS; OPERATION BY INCISION AND GOUGING; RECOVERY; REMARKS.

(Under the care of Mr. ARTHUR NEVE.)

BULAND K——, a Pathan, was admitted for very extensive syphilitic ulceration of the palate. When about to be discharged after successful treatment, he complained of much pain in the ear. Examination showed the membrana tympani bulged forward by pus. A free incision was made in the tympanum, and pus escaped. A considerable quantity exuded daily, and for a time he had relief. The escape became, however, intermittent, and the pain very intense, affecting one side of the head. To pressure there was some tenderness over the mastoid process. After two or three weeks' treatment without material benefit an operation was resolved on.

Operation.—Under chloroform a crucial incision was made, freely exposing the bone, into which, by means of a narrow gouge, a hole was drilled. At a depth of half an inch pus was reached, and a cavity containing perhaps half a drachm exposed. This was syringed out, and powdered with iodoform.

Progress.—The progress was very satisfactory. There was complete relief of pain. The operation wound closed in the course of a few weeks, and shortly after the discharge from the ear ceased altogether. The patient was discharged cured, and when last seen, a year having elapsed since the operation, was in good health, and had suffered no relapse of the ear disease.

Remarks.—Many successful cases of this operation have been recorded. In this case the marked syphilitic taint, and the acute course of the symptoms, both indicated the necessity of active treatment, and afforded a healthy prognosis. If the symptoms had been far less marked, it is probable I should have resorted to operation. There is no reason why the principles of ordinary bone surgery should not be applied to the mastoid process; with proper care no harm can result. In the more dubious cases good will frequently result. The disease, if allowed to continue uncured, is of serious import, and an operation affording any reasonable hope, and with little attendant risk, might probably be resorted to with advantage far oftener than is at present the case. I examined the ear on July 18th, 1884. The patient's hearing was normally acute, and the tympanum appeared quite healthy.

Reviews and Notices of Books.

Report on the Scientific Results of the Voyage of H.M.S. "Challenger" during the years 1873 to 1876, under the command of Captains Nares and Thomson. Prepared under the superintendence of the late Sir C. WYVILLE THOMSON, Knt., F.R.S., and now of JOHN MURRAY, F.R.S.E., one of the Naturalists of the Expedition. Zoology, Vol. VII. Published by order of Her Majesty's Government. London: Longmans and Macmillan. Edinburgh: Adam Black and Douglas and Foulis. Dublin: A. Thom & Co. 1883.

THE contents of this volume are:—1. Report on the Anatomy of the Spheniscidæ collected by H.M.S. *Challenger*, by Morrison Watson, M.D. 2. Report on the Pelagic Hemiptera collected by H.M.S. *Challenger*, by F. Buchanan White, M.D. 3. Report on the Hydroida dredged by H.M.S. *Challenger*. First part, Plumularidæ, by G. J. Allmann, LL.D. 4. Report on the Specimens of the Genus Orbitolites collected by H.M.S. *Challenger*, by W. B. Carpenter, C.B., M.D.

The Report on the Spheniscidæ, or Penguins, by Dr. Watson, extends over 242 pages, and the letterpress is illustrated by no less than nineteen plates showing the anatomy of this remarkable group of birds. The plan Dr. Watson adopted has been to select a typical specimen—the Eudyptes chrysocome obtained from the island of Tristan d'Acunha,—and to make a thorough and complete dissection of it; the variations met with in dissecting other species are carefully noted and compared with the characters of the typical form. On the whole it proved that the variations were slight.

The penguins have received a considerable amount of attention at the hands of naturalists. Cuvier, Meckel, and Owen have each given good descriptions of their osteology; Reid, Coves and Gervais, and Alix have published monographs upon one or more species, but none of these compare in fulness to the present memoir. The vertebral column in the dorsal region is remarkable for the resemblance of the vertebræ to those of reptiles in being opisthocælous—that is in the anterior surface of the bodies being globular and rounded, whilst the posterior are deeply concave, so that the convexity of each vertebra is received into the concavity of the vertebra next preceding. Dr. Watson finds this peculiarity confined in birds to the auks and penguins. He finds that there are ten vertebral ribs, the last being very slender and buried in the abdominal parietes, so that it is apt to be overlooked. The sternal ribs are eight in number. The scapula is of relatively larger size than in any other group of birds. He notices that the characteristic feature of the wing of the penguin as a whole is to be found in the great amount of compression exhibited by all the bones of which it is composed—a flattening that is probably due to the alteration of its functions, for in these birds the power of flight is lost, but the wing is converted into a paddle, which serves the purpose of propelling the bird through the water.

"In accordance with this alteration of function, the bones of the wing are so modified in form that that organ may be carried forwards, while its sharp anterior margin offers the minimum resistance to the surrounding fluid. In the backward or effective stroke, on the other hand, a broad surface is presented to the water, and instead of the wing being carried backwards, the bird is propelled forwards in accordance with the requirements of the animal. Moreover, the movements permissible between the separate segments of the limbs are much more limited than in other birds; so much so that movements of pure flexion and extension in the joints beyond the shoulder can scarcely be said to be possible. These articulations, however, admit of a very considerable amount of rotation, and consequently, instead of the limb being converted into an absolutely rigid paddle or oar, the rotation in question converts the wing into a screw-like blade, the curvatures of which are constantly varying in accordance with the amount of rotation, which the forms of the different joints permit."

On observing the movements of the wing of an Aptenodytes which recently formed part of the collection of the Zoological Society, he found that the—

"wing of the penguin is never used in the manner of a rigid oar, which would imply the *simultaneous* movement of both wings in the same direction, in order to propel the bird. On the contrary, the wings are often and, indeed, usually, brought into use *alternately*, much in the same manner as the pectoral fins of a fish, and in every movement of the wing screw-like curvatures, which are due to the rotation of the different segments of the limb upon one another, are strongly developed. In fact, a constant screwing and unscrewing of the separate alar segments upon one another take place simultaneously with the forward or backward movement of the organ as a whole."

We purpose to notice the other sections in a future number.

Principes Techniques d'Assainissement des Villes et Habitations. By A. WAZAN, Civil Engineer. Paris: Baudry and Co.

AT this moment, when the prevalence of cholera renders the necessity of sanitary improvement most urgent, our neighbours are to be congratulated on the publication of a work on the technical principles of sanitation by M. A. Wazan. This eminent engineer is one of the few persons in France who has thoroughly studied the question of domestic and public drainage. It is singular how ignorant French engineers, architects, and medical men are of the practical details of drainage. They seem to have assisted at none of the long discussions held for so many years in England on the difficulties of resisting the ingress of sewer-gas into dwellings. The great majority do not even recognise the necessity of trapping a soil-pipe. M. Wazan opens the subject by dealing with the water-supply, taking as his model town Marseilles, which has a cubic metre of water per head per day, while Paris receives only 168 litres, and this to a great extent is wasted in the streets. By engineering works of no very difficult description the water-supply of Paris could be raised to a metre per day, and M. Wazan warmly advocates this increase. With regard to water-distribution, the author is in favour of constant supply, points out all the dangers of cisterns, and urges their employment solely for flushing drains and disconnecting the water-supply from the closets.

On the all-important question of house-drainage M. Wazan has thoroughly adopted English ideas. He believes in water drainage, and, quoting Dr. Carmichael's experiments, argues that the syphon-trap is an efficient protection against the introduction of germs, which he maintains are retained in the water. We have then set before us illustrations of all the well-known traps and syphons in use in England; but in every instance the author advocates the necessity of soil-pipe ventilation. The mere outlet on the roof of the house is not sufficient, and he maintains that there should always be an inlet below, and a ventilator on the soil-pipe side of every closet syphon. Imbued by such principles, it naturally follows that all French sanitary work is condemned. Those few houses in Paris where the drainage is direct to the sewer, and an attempt is made to imitate the English system, are loudly denounced for their sanitary imperfections. Under these circumstances, and considering that everything that has been done in France has been performed badly, it is somewhat surprising to find M. Wazan quite hopeful as to the practicability of carrying out in Paris our most advanced theories on water drainage. Certainly his work will contribute greatly to this result, but one book will not suffice to educate an entire people. In England we are far behind M. Wazan's ideal. His book, it is true, is a most complimentary epitome of the best work done in this country;

Digitized by Google

but the best work is the exception to the rule, and it is doubtful whether the French can be made to at once appreciate what is scarce, even in England. If they follow English example, it will be, we fear, much in the sense already denounced by M. Wazan himself. Our blunders will be repeated, and it will take a long experience before anything like perfection is attained. Nevertheless, if this pessimist view should unfortunately prove correct, it will not be M. Wazan's fault.

A Practical Treatise on Materia Medica and Therapeutics. By ROBERTS BARTHOLOW, M.A., M.D., LL.D., Professor of Materia Medica and General Therapeutics in the Jefferson Medical College of Philadelphia, &c. Fifth Edition, revised and enlarged. New York: D. Appleton and Co.

THE revision of the United States Pharmacopœia has necessitated the publication of a new edition of this work; in it we therefore find numerous alterations and additions in that part of the volume devoted to materia medica, but the author has at the same time spared no pains to bring it up to date in all respects. Besides other new matter, we note the addition of an article on the Convallaria Majalis. Dr. Bartholow states that "the signal advantage which it offers over digitalis" in heart disease "is the absence of danger from its administration and the freedom of the cerebro-spinal axis and the digestive organs from disturbance." He points out, however, that the reports on its use "are not uniformly favourable." The article on Electricity has been much extended and improved; a section having been added on Magneto-therapy, and that on Galvanism rewritten. In this edition, too, are plates which have not appeared in previous ones. In the article on Lead we read, "Paralysis of the common extensors of the fingers and supinators, while the power of the flexors and pronators is much less diminished, constitutes the very striking phenomena of lead poisoning or wrist-drop." This is scarcely correct, the supinator longus as a rule escapes the paralysis. We are surprised to find in the section on Phosphorus no reference to its use in leucocythæmia and Hodgkin's disease; cases in which it appears to have been of undoubted benefit have been recorded by Wilson Fox, Broadbent, and others. Possibly this is an accidental omission only, as we find a reference to leucocythæmia in the index under the head Phosphorus, though there is none in the text. Some words in this volume—e.g., "fiber" for fibre, "hypodermatic" for hypodermic, appear strange to the English eye. The large circulation and the rapid succession of new editions of Dr. Bartholow's work prove its appreciation by the profession; and the admirably complete and systematic arrangement of the contents, together with the scientific way in which the subject is treated, amply justify its reputation and reception.

OUR LIBRARY TABLE.

Lehrbuch der Physiologie. Dr. A. GRUENHAGEN. Leipzig: Leopold Voss.—We have received the first two parts of this text-book, which is the seventh edition of Wagner's well-known work, two or three editions of which were published by Otto Funke; and which has now been thoroughly worked up to the present date by the learned professor of physiology at Königsberg. The treatise has always held a high place amongst works on physiology from the clearness with which it is written, the absence of unnecessary details, and the full references it gives to the principal and most trustworthy sources of information. It is by no means a mere compilation of facts strung together to aid a student in passing his examination, but a thoughtful exposition of the principles on which modern physiology rests. The two parts now issued deal with the blood and circulation and with digestion, and the whole work will appear, it is stated, in three volumes. The only previous edition we have to hand with which to compare the present is the fourth, published in 1863. We notice that the type is larger, and that whilst some judicious pruning has been practised, much new matter has been introduced. Thus, under the head of the Microscopical Relations of the Blood, the section has been much enlarged by an account of the instruments devised by Malassez, Hayem, Gowers, Abbe and Thoma, and Zeiss, and the results obtained by their use; the red and white corpuscles are more fully described, and the action of reagents upon them is better given. The theory of the coagulation of the blood, with the experiments of Schmidt and Hammarsten is discussed at considerable length, and a full description is given of the gases of the blood, yet the whole section is only augmented by a page or two. The entire work seems to have undergone careful revision, and it may be recommended as one of the best treatises on physiology extant.

German-English Medical Dictionary. By JOSEPH R. WALLER, M.D. Vienna: Toeplitz and Deuticke. 1884.—Dr. Waller states in the preface that his dictionary is founded on Cutter's Dictionary, with the addition of many descriptive terms and the omission of obsolete and unused words. It contains about nine or ten thousand words; the rendering of the English equivalents are concise, correct, and appropriate. For example, *Brand* is given as scald, scalding, burn; gangrene, mortification; caries, necrosis; *Brand in den Zähnen*, caries; *neissen Brand*, gangrene; *feuchter Brand*, humid gangrene; *trockener Brand*, mummification; *erweichter Brand*, colliquation. This is very well done. There are, however, some terms that we miss. Why are *Wagrecht* and *Schwerpunnkt* omitted?

Students' Manual of Electro-Therapeutics. By R. W. AMIDON, M.D. London: G. P. Putnam's Sons, Henrietta-street, Covent-garden.—This little book, the author says, is presented to the medical public chiefly as a protest against the mysticism and charlatanry which have ever hung around the literature and practice of electro-therapeutics. The aim of the writer has been to present that amount of knowledge of electro-physics necessary to the comprehension of the construction and use of medical batteries, to point out the chief physiological effects of electricity, to sketch the methods of electro-diagnosis, and to show the general lines of treatment. In all these respects the author has faithfully kept his word. We can strongly recommend the book to students as a good introduction to a study of the subject.

Zeitschrift für Biologie. By KÜHNE and VOIT. Band 20, Heft 3. 1884.—This part contains the following articles:—1. On the Influence of the Extractions of Meat on the Development of Animal Heat, by Dr. Max Rubner. 2. Researches on the Relation of various Amides in the Animal Organism, by Dr. H. Weiske and B. Schulze. 3. On the Quantitative Estimation of Urea by means of Bromin Solution, by H. J. Hamburger. 4. The Chemical Composition of Cartilage, by Dr. W. Krukenberg. 5. On the Normal Fæces of Carnivorous Animals, by Dr. Friedrich Müller. 6. Estimation of the amount of Nitrogen found in the Fæces which does not proceed from the Food, by Hermann Rieder. 7. The Food of Labourers in Siebenbürgen.

Public Health Tracts.—Dr. Cornelius Fox, formerly medical officer of health for a combined district in Essex, has reissued in a stout pamphlet twelve of the health tracts which he prepared during his term of official work. They relate to many important points on which the views of a skilled officer of health are especially valuable; such as the question whether enteric fever is ever spontaneously generated, the supply of rainwater to cottages in rural districts, and the principles on which legislation respecting the pollution of rivers should be based. The work is pub

Digitized by Google

lished and illustrated by Messrs. Churchill, and it will prove useful to students and others who take an interest in public health work.

New Inventions.

POCKET URINE TEST-CASE.

MR. ERNST JAHNCKE, Canonbury Works, Dorset-street, London, N., has at the suggestion of several medical practitioners introduced a useful and convenient pocket urine-testing case to the notice of the profession. It consists of a nickel-plated box of very simple construction measuring four inches in length by three in breadth, and three-quarters of an inch in depth, lined with velvet and divided into suitable compartments. The length of the box at one side is occupied by two test-tubes one within the other. When not in use a small urinometer in a satin sheath rests inside the smaller. The outer and larger is flat-bottomed and is intended to hold the urine when the specific gravity is taken. The remaining area of the case is divided transversely by a hollow partition which is ingeniously contrived to hold two books of red and blue litmus paper, while at the same time it keeps in position the other articles in the case. These are three small glass-stoppered bottles and a spirit-lamp, arranged as shown in the figure. The bottles are intended

to contain the appropriate tests for chlorides, sugar, and albumen. For the last named picric acid or other solid test is preferable from its emitting no fumes. Two other plain tube-bottles designed for Dr. Pavy's test-pellets for sugar and albumen accompany the case. They are tastefully fitted with capped corks, and their size admits of their being used to replace two of the bottles contained in the case, or *vice versâ*, at the wish of the purchaser. The fact that this is eminently a pocket case, small, neat, and sufficient, with its ease of adaptation to different methods in testing, renders it a most useful article. Not the least of its recommendations is its very moderate price.

SEIZURE OF UNSOUND MEAT.—The whole of the cargo of frozen beef on s.s. *Duke of Westminster*, amounting to about 150 tons, has been seized and destroyed by the order of the Medical Officer of Health for the Port of London. The reason for its seizure was that the meat was unfit for food on account of its being in a state of incipient decomposition.

THE THIRTY-EIGHTH REPORT OF THE COMMISSIONERS IN LUNACY.

PUBLIC attention has been so strongly directed of late to the consideration of the Lunacy Laws, and professional interest in mental diseases is so rapidly developing, that this report should obtain more consideration than falls to the lot of most Blue Books. Throughout the report no allusion can be found to any case of wrongful admission or detention in private asylums, a fact which will probably surprise those who have studied the popular lunacy literature of recent years, and will be held to be satisfactory or the reverse according to the views entertained on these subjects. To the profession it will be of interest to learn that the total of persons recognised by the Commissioners as of unsound mind was 78,598 at the end of 1883, being an excess of 1763 during the year. Satisfaction must be felt that this is not really increase, but accumulation; the ratio of first admissions into asylums during the year having been 5·15 per 10,000, when allowance has been made for the transfer of a large number of chronic imbeciles from workhouses to asylums. It is still more satisfactory to observe from Table III. that this ratio of admissions (5·15 per 10,000) is about the average for the last five years, and is decidedly less than the ratio attained during the first years of the action of the Government grant to lunatics in 1874. Private lunatics have increased in number from 7023 in 1873 to 8958 in 1883, the ratio to population having slightly diminished. The recovery rate for the year has been 38·5 per cent. on the admissions, being below the average (39·53) of the last ten years. The most valuable table in the report is that (No. XIV.) which shows the professions or occupations of the patients admitted into asylums during the year. These are grouped in accordance with the census reports of 1871 and 1881. The professional and commercial groups yield by far the largest proportions, varying from 5 per 1000 in soldiers to 3·4 in civil engineers, and 2·4 in artists to 1·0 in the teaching and lecturing class. In the commercial group travellers stand high (1·3 per thousand). In the agricultural, farriers and veterinary surgeons head the list (1·3), while shepherds and gamekeepers are lowest (·5). Of manufacturers, paper-makers are lowest (·3), while of handicrafts, plumbers, painters, and glaziers are highest (1·0). The group of persons employed in the heavier kinds of manual labour yields a lower proportion than any other (·48), miners being the lowest of its constituent classes (·3). All these proportions require correction by the ages of the persons included in the various classes and groups, and by other considerations. General paralysis was present in 13·1 per cent. of the male admissions, and in 3·2 of the females, the corresponding figures for epilepsy being 11·1 and 7·8; the latter disease existed to a much greater extent among the paupers than in the private patients, the proportions being 10·4 to 3·9. The suicides were eighteen in number, including four who were absent from asylums on trial. It would be desirable that some record should be made of suicides by insane persons not under certificates. If such cases were reported by the coroners to the Commissioners, the latter, it may be predicted, would, by investigation, obtain some valuable information in regard to the action of the present law of certification in preventing insane persons being placed under proper care. The long list of additions to existing asylums testifies to the willingness throughout the country to provide the accommodation required, and regret must be expressed that this is so often in the form of annexes for chronic cases.

The year's retrospect cannot but be considered as satisfactory, and although it might be desirable that the functions of the Commission should be extended, yet from the amount of work recorded in the report this would not appear possible without an increase in the *personnel* of the present Commission.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 20, 1884.

THROUGH the courtesy of Director-General Dr. CRAWFORD we are enabled to reproduce a very important memorandum by Dr. TIMOTHY LEWIS on the comma-shaped bacillus, stated by Dr. ROBERT KOCH to be the essential cause of cholera. The memorandum gives evidence of having been the result of much labour, and has manifestly been prepared with great care as befitting the importance of the subject brought under review. We will not attempt to epitomise what is already limited to the briefest statement of facts, and we only point out the salient features of the memorandum for the purpose of directing our readers' attention to the document itself. As might have been expected, Dr. LEWIS has taken a deep interest in the recent investigations in which the German and French cholera commissions have been engaged, seeing that, in conjunction with Dr. D. CUNNINGHAM, he had been for several years occupied with like inquiries in India. Profiting by the present vacation at the Army Medical School, he devoted a portion of his holiday to proceeding to the south of France for the purpose, as he states, of renewing his acquaintance with the disease, and of studying afresh the microscopy of the alvine discharges. As a preliminary to his reference to the results of this visit, he submits the history of the German Commission to a brief review, and the results to such criticism as has not hitherto been attempted either in England or on the Continent; indeed, thus far the history of Dr. KOCH'S progress from Berlin to Egypt, a little more than a year ago, and from Egypt to India and back to Berlin, has been a series of apparent triumphs along the whole line. The time has come, however, to submit the results of his inquiries to the test, and the full details of them which have recently been placed before the world are practically an invitation to the profession to weigh them in the scales. This Dr. LEWIS has done, and we think that our readers will be as much surprised when they reach his paper as we ourselves were.

In the first place, it is pointed out that the specific organism which Dr. KOCH believed he had discovered in Egypt was a straight bacillus, like the so-called specific bacillus of glanders; that he had, in fact, already discovered them in specimens of intestine from four natives of India which had some time previously come into his hands; but that he had looked upon their presence in the mucous membrane as due to post-mortem changes, until he again found them in connexion with cholera in Egypt, when he felt that they were sufficiently characteristic to afford material assistance in pronouncing on the identity of the disease in both countries. In the course of a few months, however, it was announced that the specific organism of cholera was not straight, but curved or comma-shaped; so that, apparently, as Dr. LEWIS remarks, the microbe first fixed upon had to be abandoned. The culminating point of importance in the memorandum is the announcement that curved or comma-shaped bacilli, identical in size, form, and in their reaction to aniline dyes with those found in cholera, are ordinarily present, to a greater or less extent, in the secretions of the mouths of perfectly healthy persons.

Seeing that as yet the sole argument of any real value which Dr. KOCH has adduced as to such organisms being the cause of the disease, is his assertion of their entire absence from the alimentary canal in any condition save that of cholera, Dr. LEWIS' discovery is one of great moment, for so widespread has the doctrine that such "commas" are the cause of cholera become, that regulations are now said to be in process of formation which shall govern the mutual intercourse of nations during periods of cholera epidemics, based mainly on the results and inferences of the Berlin Cholera Commission in India. To the correctness of the statement that "commas" of this character may be found in the saliva in health we ourselves can testify, having had an opportunity of seeing the preparations to which Dr. LEWIS refers in the table which he gives of the comparative dimensions of the "commas" found in cholera and in the secretions of the mouth. So far as could be judged by passing one slide after another through the microscope (under a sixteenth of an inch oil-immersion objective), we could detect no difference between the curved bacilli in the several slides, and, indeed, in some instances, it appeared to us that it was even easier to demonstrate their existence in the saliva preparations than in those of choleraic alvine discharges. It must be borne in mind that ordinary preparations of the latter present a very different appearance as regards the number of "commas" in the field of the microscope from that presented by "pure cultivation" of them.

Dr. LEWIS does not enter into the question of the possible existence of choleraic, as contrasted with salivary "commas," but simply takes his stand on the common-sense ground that organisms found at the termination of the alimentary canal which are of the same form and size as others found at its commencement are probably one and the same kind. Consequently the *onus probandi* that they are different lies with those who may declare such to be the case.

MR. MUNDELLA'S instruction to Mr. FITCH, when that officially-minded gentleman was directed to append a memorandum to Dr. CRICHTON BROWNE'S report, must have been substantially, if not in so many words, "No case—abuse the plaintiff's attorney." In the very endorsement of the paper to be traversed a most damaging admission is made. The plea that Dr. CRICHTON BROWNE "fired off a letter" at the department over which Mr. MUNDELLA presides is not simply abandoned, but refuted, for "Dr. CRICHTON BROWNE'S *Report*" is thus designated. It was, of course, inevitable that this admission should be made, because the opening sentence of the communication which the Vice-President has so reluctantly given to Parliament and the public cites the terms of the invitation "to inspect a few public elementary schools, and *report* to you my impression as to the effects of their work on the health of the children attending them." Moreover, it transpires that this very Mr. FITCH, who is now commissioned to pour contempt on Dr. CRICHTON BROWNE and his report, was specially instructed or requested to accompany the doctor in his tour of inspection, and, curiously enough, the doctor pointedly

Digitized by Google

thanks Mr. FITCH for his "courtesy and helpfulness." In fact the whole story lies in a nutshell. Either mistaking his man—and a remarkable passage in Dr. CRICHTON BROWNE'S letter to *The Times* on Thursday lends countenance to this conjecture—or in a moment of overweening confidence in his Department, Mr. MUNDELLA requested Dr. CRICHTON BROWNE to inspect and report on the schools under the Vice-President's official protectorate, doubtless expecting that the report would be favourable, and help to support his policy of inordinate "forcing." When, instead of support, he encountered a crushing and ruinous opposition, Mr. MUNDELLA resorted to the not very dignified or ingenuous artifice of throwing over both the report and the reporter. Had no special pressure been brought to bear on the Department, nothing would have been heard of either; but as BALAAM cursed instead of blessing, and the *contretemps* could not be kept quiet, the Vice-President has called upon his official subordinate to controvert the arguments of his quondam colleague. The manner in which Mr. FITCH has discharged his obligation in this matter *may* be satisfactory to his chief. For the sake of that gentleman we trust it has proved to be so. So far as public opinion is concerned we do not think it is satisfactory, nor can we believe that Mr. FITCH himself so regards it.

The allegations by which Mr. FITCH endeavours to discredit the report of Dr. CRICHTON BROWNE are briefly these:—1. That when he commenced his itinerary "he had no personal knowledge of the working of an educational system; that he had not, as school manager or otherwise, being concerned with the administration of schools; that he had not even been engaged in the ordinary practice which enables a doctor to know something of the children of the poor, their pursuits, and their ailments; and that he had never visited an elementary school." These allegations are probably well founded to a certain extent, though Dr. CRICHTON BROWNE does not admit the whole impeachment. It is true that the critic was not committed to an approval of the educational system he was called upon to criticise, either as school manager or as medical officer retained by authority, and therefore he *was* open to that fatal objection of the official mind—namely, that he could not approach the system on which he was to report with any traditional *penchant* in its favour. Outside the circle of "authority" these very disabilities will, if we mistake not, be held to constitute special qualifications for the formation of an independent judgment; but to Mr. FITCH—more clear-sighted than the Vice-President, who, after all, is only the parliamentary chief—they were absolute bars to the fitness of the inspector. Mr. FITCH did not unfortunately know so much as he has since learned of Dr. CRICHTON BROWNE'S disqualifications when he commenced the itinerary, or he would have put him through a little preparatory training. No inconsiderable, but a very suggestive, part of Mr. FITCH'S memorandum is occupied with an elaborate statement of the precautions he would have taken to prepare the mind of Dr. CRICHTON BROWNE—or, in other words, to have secured a favourable report,—if he had only been better acquainted with the shortcomings of the critic confided to his pilotage. We can fancy how in the [illegible] Mr. FITCH [illegible] pointed out to [illegible] so dangerous [illegible] of the [illegible]

much trouble and difficulty the undisciplined zeal and thoughtlessness of a party chief may bring down on the authority of a Government bureau! The same sort of thing has happened in other Departments, but for the most part they are both controlled, and the closure and the gag are more readily administered. So much for the preliminary objection; let us pass on to the others. 2. The schools inspected by Dr. CRICHTON BROWNE were not fair—i.e., favourable—specimens. In the amplitude of his courtesy and ignorance of his *protégé* Mr. FITCH took Dr. CRICHTON BROWNE to the very schools to which he would *not* have introduced him if he had only known the facts. In short, he showed the nakedness of the land to the man he mistook for a friend, but has since discovered to have been a spy. In his letter to *The Times* the critic directly contradicts this statement. 3. Dr. CRICHTON BROWNE'S method of investigation is "neither prudent nor trustworthy." He stands before a class, say of sixty boys, asks all who ever have headache to hold up their hands." He even does worse than this in the opinion of Mr. FITCH, for "he proceeds to ask all who feel it at the back of their heads, at the top, on the forehead, all those who suffer from it in the morning, in the afternoon, in the evening, successively to hold up their hands." We do not like to hint at the bare possibility that there can be any subject of which Mr. FITCH is ignorant, or we might venture to suggest that perhaps this injudicious and untrustworthy proceeding on the part of Dr. CRICHTON BROWNE was really intended as a crucial test of the accuracy of the statement made by the boys. It may be—we merely say it may be—that a headache is a sort of thing that can only be investigated by asking questions of the sufferer, and that the best possible means of forming a judgment as to its nature and cause would be to ascertain the precise point to which it was referred, so that if a boy complaining of a headache said it was in the front when it ought to be in the back, or *vice versâ*, he would stand confessed as an impostor, or his pain would be shown to arise from some irrelevant cause. We offer this suggestion to Mr. FITCH with much deference, because obviously unless one has been a school doctor under the Educational Department, it is impossible to form any trustworthy opinion. At this point, however, there is one incident which we really must take leave to press on Mr. FITCH'S attention. Granted that he started—as he says he did—in ignorance of Dr. CRICHTON BROWNE'S want of judgment and untrustworthiness and of the badness of his method, how came it to pass that when these defects became apparent, as they must have been after Mr. FITCH had observed his procedure at two or three schools, he did not take him to some of those better establishments where the boys and girls have no headaches, or in official disgust throw up the business? By going on with the inquiry in spite of his discovery that the investigator was incompetent, Mr. FITCH has left it open to ill-natured people to say that he waited until the report was sent in to see the conclusion arrived at, and that if this had only been favourable, the badness of Dr. CRICHTON BROWNE'S method would not have been exposed. As it is, Mr. FITCH contents himself with denouncing the method, and seems to feel aggrieved that Dr. CRICHTON BROWNE did not adopt the plan which proved so successful at Do-the-Boys Hall, and introduce the subject of headaches with a flourish of the [illegible]

Digitized by Google

children who, as it happened, alleged headaches, might be induced to consider whether these maladies did really exist.

For the rest, Mr. FITCH simply contradicts Dr. CRICHTON BROWNE'S assertions, and pours contempt on his conclusions. This is how he disposes of them:—"I do not hesitate to say that every one of the judgments which purports to have been formed from Dr. BROWNE'S visits to schools appear to me to be hasty and inaccurate, and to have been arrived at by a loose and partial method of inquiry." This is a tolerably bold and strong statement of opinion, and we are not surprised to find its author moved to avow that he makes it "under a considerable sense of responsibility." Had Mr. FITCH considered the matter a little further, he would probably have found the sense of responsibility increase until it reached a degree of tension that caused him to refrain from making the statement at all. Dr. CRICHTON BROWNE in his letter alleges that in the haste of his rejoinder Mr. FITCH has fallen into many mistakes of fact. Notwithstanding the memorandum of Mr. FITCH, Dr. CRICHTON BROWNE'S report will be accepted by the medical profession and, we believe, by the community at large, as the expression of a carefully formed and clear judgment by an exceptionally competent and candid critic. The fact that the conclusion arrived at is not in consonance with the judgment which the Educational Department has formed of its own work, but directly opposed to and strongly condemnatory of the policy of indiscriminate brain-forcing, which has found favour with Mr. MUNDELLA and his subordinates, will not be considered a proof that the Department must be right and its critics wrong; nor unless we misjudge and under-estimate the power of public opinion, will it be allowed to bolster up the system of "grinding tyranny" which not only Dr. CRICHTON BROWNE, but the majority of competent observers, condemn.

THE principal interest as to the present cholera epidemic in Southern Europe centres in Naples, where the intensity of the disease exceeds anything that was experienced in either Toulon or Marseilles. Following upon occasional rumours as to suspected or well authenticted cases of the disease, two definite cholera deaths were admitted to have occurred in Naples on August 27th last. With the exception of one day on which no death took place, the daily deaths varied from one to three up to September 2nd, when a sudden increase occurred, and 67 fatal attacks were registered. A slight abatement then ensued, but within a few days the mortality rose first to 113 on September 7th, then to 275 the next day, and on September 9th the highest mortality of the epidemic was recorded, no less than 493 fatal attacks being returned by the authorities. This terrible severity was maintained for several days, but since the 12th inst. there has been a tendency to abatement. The daily number of deaths, however, still exceeds 250. Unfortunately for its future prospects, Naples is in a thoroughly bad sanitary state, and it is evident that cholera, once imported into the city, found amidst its filth a soil congenial to its further development and spread. The state of panic and confusion which have reigned there, and in other parts of Italy, is lamentable. At Naples the food-supplies ran short, the hospitals became overcrowded to an extent that is almost incredible, and which removed almost the only chance of recovery remaining to many of the patients, and the burial of the dead became partially suspended for lack of the needed materials and labour. The visit of the King of Italy and of Prince AMADEUS to the stricken city, the calm heroism which accompanied that visit, and the improvements which were effected in consequence of the KING'S orders and advice, tended materially to raise the hope of the population. But no such visit can clear away the results of generations of sanitary neglect, and the prospect is one which must still be regarded as of considerable gravity. Fortunately for Italy, which needs to be spared any further calamity, the period which has now elapsed since the KING left Naples enables us to speak with confidence as to his having escaped infection; and we are glad that in a city where he was necessarily exposed to conditions of excremental contamination of air of a peculiarly dangerous sort, the precautions adopted of securing all his food supplies and water from Rome have been successful.

From the public health point of view, the contrast so far exhibited between Rome and Naples is very striking. Cholera was imported into both cities. In Naples, it was met by the very conditions known to favour its diffusion, and a terrible epidemic has resulted; in Rome it found a city prepared with means for the immediate isolation of the earliest attacks, an improved system of sewerage and water-supply, and a state of substantial advance in matters affecting the health of the people; and though more than once imported, the disease has on each occasion been stamped out. In the interests of sanitary progress it is sincerely to be hoped that the improvements effected in the Eternal City may still stand its population in good stead.

At Spezzia and several other places a serious mortality is still maintained, but there are at last some indications of abatement. The news from France is to the effect that occasional deaths still occur in and about the previously infected cities, towns, and villages, and that in some of the smaller places fresh outbursts from time to time take place. On the whole, however, it may somewhat confidently be anticipated that no serious aggravation of the epidemic is now likely to recur. The news from Spain is both contradictory and very uncertain, but although the disease still remains prevalent in such places as Elche and Novelda in the province of Alicante, it does not appear to have made any material headway; and this gives hope for believing that serious extension may, after all, be avoided this year. The lessons of the epidemic have, even at this stage, not been altogether thrown away. Thus, both in France and Italy, the folly of putting any trust in land quarantine, a system which received nothing but condemnation at the Vienna Conference of 1874, appears now to be recognised, and it may be hoped that this false prop being removed, measures will be adopted for replacing it by something more trustworthy; that the abounding filth conditions of so many towns and villages in Southern Europe will be removed; and that means for proper isolation will be prepared, and so held in readiness as to be capable of immediate application whenever they are necessary. The present epidemic has shown the costliness of preventable disease in more ways than one. Tourists have avoided the infected countries, and already inquiry is being made as to how far it may be safe for invalids to visit the Riviera and the other

Digitized by Google

southern resorts to which so many English flock during the period which commences with our November fogs and continues till our cutting March winds have ceased. We regret to say that the history of former epidemics in Southern Europe supplies a by no means favourable answer. Thus, when cholera was epidemic in France, fresh invasions of districts and departments continued right up to the end of December; and again in 1873 cholera maintained itself in certain towns up to December 11th, and appearing in Paris on September 5th, it continued there three months, causing 855 deaths. So also as regards Italy; cholera breaking out in 1865 continued through the winter of 1865–66, and it had not ceased in the following spring. That cholera will necessarily be maintained or recur in the districts hitherto affected we do not wish to imply, but where the disease has prevailed in connexion with sanitary circumstances favourable to excremental contamination of air and water, the chances of a renewed or maintained diffusion, owing to retention of the poison, will probably not be inconsiderable; therefore we would advise intending visitors to warmer climates to seek those towns and watering-places which lie at some considerable distance from the infected localities, and to which the disease shall not have extended when the time for migration arrives. So far as we can judge at this date, the south-western coast of France and a very large portion of the coast of Spain, together with Algiers, will be far safer places of residence than many localities along the Riviera. The lapse of another month will, however, tend to clear up doubts that may now exist on this point.

IN the new Royal Warrant of June 10th for "the pay, promotion, and non-effective pay of the army," which has just been issued from the War Office, a clause of great importance has been inserted, regulating the tenure of the professorships in the Medical School at Netley. Hitherto there has been no rule laid down respecting these appointments, which, with the exception of the chair of Military Hygiene which became vacant in 1876 by the lamented death of Professor PARKES, have been filled by their present occupants for the last twenty-five years. While stringent rules have been made and enforced for the retirement of officers of all grades and departments in the army after certain periods of service, or on attaining a specified age, the appointments of the professors entrusted with the special instruction of all medical officers entering the Department have been left untouched, and superannuation has been a term unknown to them. The War Office authorities appear at last to have awakened to the necessity of adopting some measure to ensure the teaching power being kept up to the mark, and provision being made, by the renovation of its staff, to prevent the school becoming a Sleepy Hollow. ARNOLD was of opinion that fifteen years was a sufficient limit for the tenure of the head mastership of a school by any teacher, and the War Office seems to have recognised the practical value of such a rule as applied to the professors, masters, and instructors in the various educational establishments for officers of the Army. As regards the Medical School, the regulation adopted is as follows:—"The [illegible] office of the [illegible] Military Medical [illegible] India, [illegible] shall not be extended beyond fourteen years, or beyond the attainment by the officer of the age fixed for his retirement from his rank, whichever may happen first. In the case of a civilian being appointed a Professor of the Army Medical School, the term of office shall not continue after the age of sixty-five years."

Under this regulation two of the Professorships will at once become vacant, the chairs of Military Medicine and of Military Surgery. Dr. DE CHAUMONT, who occupies the chair of Military Hygiene, having entered upon his second septennial period, will doubtless be retained till he has completed fourteen years; while Dr. AITKEN, the Professor of Pathology, will continue to hold his appointment till he attains the age of sixty-five. We consider this move on the part of the War Office to be most judicious, and likely to promote the efficiency of the important medical school at Netley. However much we may regret the retirement of individual professors, we cannot doubt that their place may be efficiently filled up, and that the infusion of young blood into the establishment will promote its utility and, we trust, remove the charge against it that the splendid opportunities afforded by Netley Hospital have not been more fully utilised in the interests of the profession, and especially of the army medical officers. But while we thus approve of the step taken by the War Office, we cannot but regret that no similar provision has been made in the case of another very important body connected with the medical department—the Army Sanitary Committee. From the Army List it appears that Dr. SUTHERLAND has held an appointment on it for upwards of twenty-two years, and from his professional standing he must have considerably exceeded the age laid down as the limit of all army service. We are well aware that he has rendered very good service in that capacity, but the same reasons which have called for the regulation as regards civilian professors in the school apply to him. A period must arrive in every long life when the powers of mind and body become unequal to the amount of work demanded of them in performing important duties, and it is manifest that the question of when that period has arrived cannot be left to the individual most personally interested. Few, very few, men are willing to acknowledge that their day is gone for active work, and hence the necessity for an official limit to an official career. We believe the subject has only to be brought to Lord HARTINGTON'S notice to ensure in the interests of the Service some such regulation being extended to the Army Sanitary Commission.

IT was rightly stated by Lord RAYLEIGH in his Presidential address to the British Association that it is remarkable how many of the playthings of our childhood give rise to questions of the deepest scientific interest. "The truth, or may be understood," he continued, "but a complete comprehension of the kite and of the soapbubble would carry us far beyond our present stage of knowledge." Similar language to that used by the physicist might be held by the biologist, and we might well say if we possessed a thorough knowledge of the simplest mass of protoplasm that can present itself to our observation, we should occupy a more advanced standpoint than that on which we are at present compelled to rest. Great credit is [illegible] to

Digitized by Google

those who by the study of some elementary subject seek to obtain general principles which are of far-reaching importance. Such work was done by GRAHAM in his admirable researches on the phosphates, and on the process of osmosis, and such work has lately been done by ENGELMANN, who has contributed an excellent memoir on protoplasm movement to the "Handbuch der Physiologie," of HERMANN, which has just been translated by Mr. BOURNE, and published in the *Quarterly Journal of Microscopical Science*. In this memoir Professor ENGELMANN points out that protoplasm possesses not only contractility indicated by the movements it can effect, but irritability indicated by its response to external stimuli and automatism, or the power of initiating movement without any apparent excitation from without. The movements of protoplasm are to be distinguished from the movements which occur during the growth and reparation, and the segmentation and fertilisation of cells, principally by its greater rapidity and the absence of any relation to growth and reproduction, though the limits between the two cannot be sharply drawn. The characters of protoplasm are that it is homogeneous and transparent, almost always colourless, with a refraction index that is higher than water but lower than oil. It is, at least in some instances, doubly refracting in regard to light; it does not mix with water, but can imbibe it; is cohesive and extensile, with but little elasticity. As a rule there is no investing membrane, so that solid particles can be ingested by the outer layer of the body at any chosen spot. It generally presents granules and vacuoles. The granules may be albuminous or fatty, or consist of calcium carbonate, and often present Brownian movements. The vacuoles result from the separation of the fluid in the form of small droplets. In life the reaction of protoplasm is alkaline. ENGELMANN describes three kinds of movement, which he names respectively amœboid, streaming, and gliding. These movements only take place within certain limits of temperature below 0° C. and above 40° C. They are arrested at once and always above and below these limits, the protoplasmic mass usually assuming a rounded form and passing either into a state of cold or heat rigor. The withdrawal of water sends it into a state of dry rigor; but it is remarkable that saline solutions which prove fatal when added suddenly to protoplasm can be borne when the concentration is gradually effected, the organism appearing to be able gradually to accommodate itself to the unusual conditions. The presence of oxygen, though not necessary for the manifestation of movement, is necessary for its maintenance. Pressures of oxygen gas equal to from three to six atmospheres kill protoplasm. Stimuli of various kinds, mechanical, chemical, thermic, or electrical, all seem to impede the movement and to tend to cause retraction of processes and the gathering up of the mass into a compact ball. From the consideration of the various phenomena presented by the different kinds of protoplasm, ENGELMANN believes that we may regard it as an aggregate of most minute contractile excitable form elements, and that the movement as a whole is the result of changes of form of these very small elements. The nature, however, as well as the causes of the changes of form of these elements, remain for the present undetermined. Perhaps with improvements in the microscope, perhaps with the aid of colouring agents, some further insight into the actions and processes taking place in protoplasm may be ascertained.

No one can fail to be struck by the apparently increasing number of suicides. It may be that the total percentage of these distressing deaths upon the increment of the population has not increased, but it is beyond question that suicide, as a social calamity, has been thrust on our notice of late more than in remoter years. Until the statistical facts are made clear it would be idle to speculate as to the probable cause of this increase, if there be one. It is, however, not merely permissible, but politic, to bestow a passing glance on the subject as a whole. Suicides may be divided roughly into two great classes: those in which the self-slayers are intentionally conscious of what they are doing, and those in which they are either unconscious of their acts or perform them under distinct hallucinations or delusions of idea. This last class—which if not technically definitive will serve for our immediate purpose—is not, we think, a large one. Without hair-splitting, it may roughly be said that the great majority of those who kill, or try to kill, themselves in these modern times and in civilised communities are perfectly well aware of the nature of the act they are performing or attempting, and do the deed with a, so far, intelligent purpose of escaping from misery which seems unendurable, or because of some terror or shame that for the time overwhelms them. The law is mercifully interpreted for the sake of survivors; but, as a matter of fact, scarcely one in a hundred of the so-called cases of "temporary insanity" are correctly so described. It is heart-breaking or brain-tearing trouble that makes men and women long to die or impetuously seek refuge in death, either in the belief that in dying they will sleep or that consciousness will end in eternal oblivion. We do not say that there is a clearly defined process of reasoning in all these cases, though in the majority we believe there is; but in very few instances indeed is the real inner feeling one which differs greatly from the yearning to escape—anywhere, anywhere out of this misery. The rate at which men and women live nowadays has something to do with this feeling. Boys and girls are men and women in their acquaintance with, and experiences of, life and its so-called pleasures and sorrows, at an age when our grandparents were innocent children in the nursery. The young men of the day are *blasé* at two- or three-and-twenty, the young women *ennuyée*. Life is played out before its meridian is reached, or the burden of responsibility is thrust upon the consciousness at a period when the mind cannot in the nature of things be competent to cope with its weight and attendant difficulties. All this has been said before. There is not a new word or a new thought in it, and yet it is a very terrible and pressing subject. We cannot give it the go-by. "Forced" education commenced too early in life and pressed on too fast is helping to make existence increasingly difficult. We are running the two-year-olds, colts in a crippling race, and ruining the stock. If able and impartial observers would make it their business to ascertain the facts about suicide, they would be doing a good and useful work. We believe, not without some data upon which to base our speculations, that suicide *is* increasing, and that the active cause of the evil is mind-weakness the result of forced development and premature responsibility. Hasty

Digitized by Google

and too early marriages, too anxious struggles for success in life, too hazardous ventures in business enterprise, the rush of undisciplined and untrained minds into the arena of intellectual strife, and, above all, that swinging of the self-consciousness—pendulum-like—between excess in rigor of self-control and untempered licence, which constitutes the inner experience of too many, are proximate causes of the breakdown or agony of distress which ends in suicide. The underlying cause is impatience, social, domestic, and personal, of the period of preparation which nature has ordained to stand on the threshold of life, but which the haste of "progress" treats as delay. It is not delay, but development; albeit this is a lesson rash energy has yet to learn from sober science.

Annotations.

"Ne quid nimis."

JOHN NETTEN RADCLIFFE.—IN MEMORIAM.

THE death of John Netten Radcliffe not only leaves a widow and her children in mourning, but sensibly depresses a great many members of the medical profession, and would have depressed them much more had not his death been preceded by a long and sad illness that almost reconciled even his friends to parting with him. For nearly two years, under the strain of work of the very best sort, all that was most precious in our friend in mind and body had failed. We try to forget how completely. In another column the nature and bearings of his work are set forth. Here we only give ourselves up to mourn over all that we have lost. To this journal he was no casual contributor, but a guide whose judgment was invaluable in crises and panics when the judgment of most men is apt to be at fault. Under his view the march of epidemics seemed regulated, they were bereft of half their terror, and the true line of duty and safety became clear. In 1866 his prompt and clear investigations put sharp limits to the cholera, and have secured comparative immunity and serenity since. Nor was the value of his judgment confined to questions of public and preventive medicine. He was a wise and experienced practitioner, and choice and a classical in his general and medical reading. There was a wonderful mixture of gravity and humour in his mood. The humour generally prevailed, and though often deep and keen, was always good natured and kind. Only those who had the advantage of knowing him somewhat intimately can tell how kind Radcliffe was, or how deep and practical was his sympathy. It amounted to a strong human affection extremely precious in all the great circumstances of life, and always most reliable when it was most needed, no matter what the trouble, or even the cost, to himself. If there was one part of his nature not sufficiently controlled by his good judgment it was this part. We have not yet heard the last of John Netten Radcliffe. He will be long remembered as one of the men who, under Mr. Simon's masterful lead, has placed the sanitary condition and organisation of this country high in the respect of civilised nations, though still far from realising their ideal. Not the least noticeable feature in Radcliffe was his patience with vestry and board of guardians' human nature. There was so much human nature and common sense in himself, that he could be tolerant even with sanitary authorities and with those who were "out" of sanitary ways. Such is the friend we have lost, such the man lost to the public service all too soon and at a comparatively early age. The work of the public service is very exacting and the remuneration inadequate. The death of Radcliffe, and all its circumstances, may raise the question how best to reward such lives as his and such services as he rendered. Our object here is more limited—we had almost said personal.

DISINFECTING THE SPUTA OF PHTHISIS.

DR. J. SORMANI, Professor of Hygiene at the University of Pavia, gave some interesting details at the Hygienic Congress of the Hague concerning experiments made this year on 150 guinea-pigs with the sputa from phthisis. The object in each case was to ascertain what chemical or other methods would neutralise the bacillus, which it was previously ascertained existed in large numbers in the sputa. The results of these experiments were summarised in the following manner:—1. The bacilli of tuberculosis were generally very difficult to destroy; dryness, exposure to oxygen, putrefaction, and most disinfectants failed to produce any effect. 2. A temperature of 100° C. only killed the bacilli after at least five minutes of ebullition. 3. The artificial digestion of bacilli showed that they were the last of all living organisms to be destroyed by the gastric juices or chloridric acid. A very active digestion is necessary to kill this microbe. A healthy man may destroy the bacilli in his stomach, but an infant or an adult with his digestive faculties impaired would easily allow the germ to pass the stomach intact, and retain its virulence in the intestinal tube. This determined enteric ulcerations &c. 4. The bacillus of tuberculosis can be preserved intact for a whole year when mixed with water. It is probable, though not proved, that it has retained its virulence during that time. Thus drinking water may become the means of propagating tuberculosis. It is probable that contaminated linen retains its virulence for five or six months. 5. Alcohol does not destroy the germ, and hard drinkers often suffer from tuberculosis. 6. Cod-liver oil, ozone, oxygenated preparations, and other similar remedies, have no effect in killing the bacillus, nor are benzoate of soda, salicylate of soda, sulphate of zinc and carbolic acid, iodide of silver, bromide, camphor, &c., of much greater use. They injure perhaps, but do not absolutely destroy the bacillus, at least not in the doses that can be taken without danger. 7. A more decisive action may be attributed to creasote, eucalyptol, pure carbolic acid, the naphthols, and bichloride of mercury. 8. For disinfecting spittoons, carbolic acid solution at 5 per cent. is thought sufficient, and Dr. Sormani asserts that the breath never contains any bacillus. He also suggested that essences of turpentine or eucalyptol should be diffused in the houses as an agent for the destruction of this special germ.

THE FRANKLIN BAY EXPEDITION.

THE account of the medical history of the survivors of the Lady Franklin Bay expedition just given by Dr. Green in the *Medical Record* of New York is full of interest. The unfortunate men who composed the expedition having subsisted on starvation rations for nine months, having nothing but brackish water to drink, no artificial warmth, and living almost continuously in a hut which gave only seventy cubic feet of space per man, were reduced in number from twenty-five to seven, whilst the survivors when rescued were *in extremis*, and were only restored by the greatest care and attention. During the first four months each man received a daily allowance of 14·88 ounces, composed as follows: Meat and blubber, 4·33 ounces; bread biscuit, 6·5 ounces; canned vegetables and rice, 1·4 ounce; butter or lard, 0·75 ounce; soup or beef extract, 0·90 ounce; berries, pickles, raisins, and condensed milk 1 ounce; in addition, the following casual contribution to their larder was made—two seals, one bear, eight foxes, and sixty dovekies. Such was their diet from Nov. 1st to March 1st,

Digitized by Google

during the cruel winter months, considerably less than one-half the amount required for healthy nutrition, and a bad preparation for the further reduction that followed. During this period, however, only one death occurred, and that from scurvy, the only case that exhibited decided symptoms of that disease among the crew. On March 1st the ration was reduced to meat 6·8 ounces, dry biscuit 3·2 ounces, and an allowance ranging from 1 ounce to 3 ounces of a small crustacean, consisting of four-fifths shell and one-fifth meat; after May 12th, however, no regular ration was served out, and they subsisted entirely on the shrimp, reindeer moss, and the gelatin obtained by boiling the sealskin lining of their sleeping bags. With a view of approaching a state of hibernation, the men, except those told off to collect food, remained in their sleeping bags for sixteen or eighteen hours at a stretch. The men rapidly died, and on June 22nd only seven survived. Those who succumbed died with symptoms of hydrops pericardii. The survivors were found emaciated and anæmic to the highest degree, their bodies emitting a sickly odour of stale urine, and their face, hands, and scalp blackened with soot and dirt; they were excitable and irritable, almost irrational, and ravenously hungry; respiratory movement 12 per minute; pulse 52, soft and compressible; hæmic murmurs over base of heart; bowels obstinately constipated; urine almost suppressed. Temperature 97° F. under tongue. On giving food the urine discharged in the first twenty-four hours became more abundant, but was highly albuminous, and continued so for some time. The account of the sufferings of these men and the symptoms exhibited by the survivors correspond to those detailed by Dr. Richardson in the Franklin Expedition of 1821. Some surprise has been expressed with regard to the absence of scurvy, only one of the men exhibiting decided scorbutic symptoms; but the conditions which bring about this disease were fortunately absent. It is true they had no lime-juice; but during the earlier period the dietary was not of a scorbutic character, as they had berries, pickles, and blubber, which the experience of the Eira Expedition shows possess antiscorbutic properties. In the later stage they were able to collect a sufficient quantity of reindeer moss, which has been abundantly proved by the records of numerous Polar expeditions to be an effectual antiscorbutic. There is, therefore, no reason to think that the experience of Lieutenant Greely's Expedition will modify existing theories regarding the cause and prevention of scurvy. That disease, as has been abundantly demonstrated, is not produced by mere starvation, for so long as in the most scanty dietary there is present an antiscorbutic element, scurvy will not make its appearance.

IMMUNITY FROM CHOLERA AT HYERES.

IN the study of the present cholera epidemic, the position of Hyères is destined to attract a large share of public attention, for the experience acquired in this town offers a twofold interest. First, it is the most ancient, the nearest, and one of the most economical of all the winter stations on the Riviera. It is extensively patronised by the English, and possesses a great variety of climatic advantages which are not easily found even in this favoured region. Secondly, Hyères is within walking distance of Toulon. Eleven miles of orange, olive, and almond groves, of market gardens, strawberry fields, and vineyards, separate this little town, with its 12,000 inhabitants, from the original centre of the cholera epidemic. Naturally, a large number of fugitives, estimated, we are informed, at about fifteen hundred in all, took refuge at Hyères. Of course, out of so large a number there were some who had already contracted the disease at Toulon, and fell ill on reaching Hyères. Dr. E. Vidal, however, whose eminent services were recently rewarded with the Legion of Honour, writes to assure us that none of these cases determined a local outbreak. Hyères, like all the other towns of the Riviera, is still in an insanitary condition—that is to say, most houses have cesspools, pipes remain untrapped, and such sewers as exist are for the greater part defective. But the same may be said of every other town on the Riviera, indeed of every town in France, including Paris. On the other hand, the Municipality of Hyères deserve the warmest praise for their energetic efforts to minimise the evil effects of this state of things. Every watercourse, gutter, and sewer has been carefully and frequently disinfected, and the streets washed three times a day. After each case imported from Toulon the room of the patient was disinfected by the burning of sulphur. This procedure will, we trust, be continued long after the cholera epidemic has ceased, and be applied in all cases of eruptive fever. But something more than this is requisite to account for the remarkable immunity of Hyères. Nearly all the vegetables consumed at Toulon are supplied by the market gardeners of the former town; in fact, the relations between the two towns are those of a suburb to a metropolis. Refugees from Toulon have determined the outbreak of cholera in a number of villages and towns; yet, though Hyères was the nearest town and harboured the largest proportion of refugees, no harm has accrued to its inhabitants. The probable explanation of this phenomenon lies in the granitic nature of the soil. The town, in fact, is built on a rock, an offshoot of the Maure mountains. It has also an excellent water-supply, pumped up from a considerable distance, and not likely to be contaminated. The non-porous nature of the soil, the pure water-supply, and the exceptional cleanliness and rigorous disinfection have so far saved Hyères; but for these fortunate circumstances, it seemed inevitably condemned to share with its neighbour all the horrors of the Toulon epidemic.

COHNHEIM'S LIFE-WORK.

THE subjoined is a list of the literary labours of the late Professor Cohnheim. It is appended to a lengthy and appreciative memoir of his late friend by Dr. Weigert of Leipsic (*Berl. Klin. Wochenschr.*, Sept. 1st), which we should have been glad to reproduce did space permit. This catalogue, however, serves to show how actively and laboriously, and with what profit, Cohnheim worked within the comparatively brief space of twenty years. Were all the writings done by his pupils in the laboratory under his direction added, the list would be far more extended. Weigert gives many of these, but admits that his list of them is incomplete:—Dissertatio de Pyogenesi in Tunicis Serosis, Berlin, 1861; on Inflammation of Serous Membranes, Virchow's *Archiv*, Bd. 22; on Sugar-forming Ferments, ibid., Bd. 23; a Case of Abscesses in Amyloid Organs, ibid., Bd. 33; Two Cases of Mycosis of the Lungs, ibid., Bd. 33; Fatal Trichinosis with Parenchymatous Degeneration of Liver, Heart, and Kidneys, ibid., Bd. 33; on the Terminations of Muscular Nerves, ibid., Bd. 34, and *Centralblatt für Med. Wissensch.*, 1863; on the Minute Structure of Striated Muscle Fibre, Virchow's *Archiv*, Bd. 35; the Pathological Anatomy of Trichinosis, ibid., Bd. 36; Results of an Anatomical Examination of a case of so-called Muscular Hypertrophy (with Eulenberg), Transactions of the Berlin Medical Society, Bd. 1, 1866; Death from Rupture of Varices of the Spleen, Virchow's *Archiv*, Bd. 37; a case of Ileus due to a Gallstone, ibid., Bd. 37, 1866; Metastasis in Cancer of the Stomach, ibid., Bd. 38, 1867; on the Terminations of Sensory Nerves in the Cornea, ibid., Bd. 38, 1867; a Case of Multiple Exostosis, ibid., Bd. 38; on Tuberculosis of the Choroid, ibid., Bd. 39, 1867; on Inflammation and Suppuration, ibid., Bd. 40, 1867; on

Digitized by Google

Venous Stasis, ibid., Bd. 41, 1867; Experimental Researches on the Communicability of Tuberculosis to Animals (with Bernh. Fränkel), ibid., Bd. 45, 1868; on the Behaviour of Fixed Connective Tissue Corpuscles in Inflammation, ibid., Bd. 45, 1868; on Amyloid Degeneration, ibid., Bd. 54, 1871; Researches on the Embolic Process, Berlin, 1872, Hirschwald; on Keratitis, Virchow's *Archiv*, Bd. 61, 1874; Congenital Striated Muscle-Sarcoma of the Kidneys, ibid., Bd. 65, 1875; on the Results of Embolism of the Pulmonary Arteries (with Litten), ibid., Bd. 65, 1875; on Derangements of Circulation in the Liver (with Litten), ibid., Bd. 67, 1876; Simple Colloid Goitre with Metastasis, ibid., Bd. 68, 1876; Disease of Bone-marrow in Pernicious Anæmia, ibid., Bd. 68, 1876; on Hydræmia and Hydræmic Œdema (with Lichtheim), ibid., Bd. 69, 1877; on Artificial Tuberculosis—Inoculation in the Anterior Chamber of the Eye (with Salomonsen), Reports of the Schleswig Society, 1877; on Acute Pulmonary Œdema (with Welch), ibid.; on the Theory of Tumour Metastasis (with Maas), Virchow's *Archiv*, Bd. 70, 1877; on the Sphere of Pathological Anatomy, Leipsic, F. C. W. Vogel, 1878; on the Effect on the Heart of Obstruction of the Coronary Arteries (with v. Schulthess-Rechberg), Virchow's *Archiv*, Bd. 85, 1881; Tuberculosis as an Infective Disease, Programme of the Medical Faculty of Leipsic, 1879, and by Edelmann, Leipsic, 1879 and 1881; Researches on the Renal Circulation (with Charles Roy); Lectures on General Pathology, Berlin, Hirschwald (1st Edition, Bd. 1, 1877; Bd. 2, 1880; 2nd Edition, 1882).

WATER CISTERNS.

WITH the knowledge that cholera is active in several countries having direct commercial intercourse with England, the state of the water-supply in certain parts of our large towns is not pleasant to think of. Where nothing can be said against the quality of the water itself, the manner in which the house-supply is contrived—the single cistern method—leaves much to be desired. Certain points must be attended to in order that any cistern should meet its requirements satisfactorily. It must be well constructed, well placed, well covered, and well kept. The days of faulty construction are not yet over, but errors in this respect are becoming less and less frequent. The general adoption of zinc lining has removed one source of danger. Pipe connexions, however, are still far from perfect. The overflow, it is true, in many cases finds its outlet above ground, instead of into the sewer as formerly, but the cistern still continues to furnish one common supply for waterclosets and for drinking purposes. The use of water-waste preventers in some districts has indeed placed an efficient trap on the closet communication, but the value of this improvement is limited by its sparing application. A still further stage in sanitation is reached, and that but rarely, where a house is fortunate enough to possess a separate cistern for either purpose. Easiness of access, seclusion from light, and from extremes of heat and cold are important in reference to the position of every such reservoir. One finds, nevertheless, that it is often placed outside the house altogether, high above the ground, and sometimes inaccessible by any door or window. Hence it is exposed to frost and flying dust, and is but rarely cleansed out. If due regard be had to ventilation, it were in every respect much better indoors. A well-fitting lid, not a mere lath sheeting, forms the most suitable cover. Cisterns which fulfil the necessary conditions of structure and relation should not be difficult to keep in order. Whether they shall be so kept must depend upon the industry of their owners. Among rich and poor cases of neglect occur, be the arrangements what they may, and if this be so it is not surprising that the slums should show many instances of gross and filthy carelessness. In them the water-supply is most sparing and the means for its provision unscrupulously economical. Undoubtedly the fittest remedy in their case would be the introduction of a constant service system. The trouble of large cisterns would thus be done away with, and with them one source of danger would be abolished. Wilful waste need hardly be feared, nor perhaps need one expect so poor a population to be carelessly lavish in their use of water for drinking or for personal cleanliness. Plain fittings, their practical purpose once appreciated, would offer no great inducement for theft. This system has been successfully employed in many parts of the country. Its introduction amongst the poorest classes of large towns is little short of a necessity.

SMALL-POX IN LEICESTER.

THE anti-vaccinationists in Leicester now awaiting summons are said to number three thousand. In view of the magnitude of the necessary legal proceedings, application has been made by the local authorities to the Local Government Board for advice in the matter. In the meantime small-pox has made its appearance, and it is singular to learn, yet after all natural, and, we may add, creditable to the common sense of the townspeople, that vaccination has been resorted to in order to prevent it spreading. The precaution comes late, but it may be hoped not too late, to interfere with the experiment on a large scale to which so many inhabitants of the town have rashly devoted their children. The mildness of the present epidemic and its comparative limitation, results almost exclusively due to efficient vaccination in other parts of the country, have much to do with the immunity hitherto enjoyed by Leicester. But it is remarkably true in the experience of every medical practitioner that wherever there are susceptible, that is practically unvaccinated, persons, there, if anywhere, the pestilence will strike. We are not, therefore, surprised that the period of immunity has ended. We do not doubt that the Local Government Board will know how to uphold a sanitary measure as right as it is necessary, even while using such consideration as may be due towards offenders who are possibly misled rather than perverse. The fear is not vain that if their opposition should continue, another monitor—adversity—may yet lead them roughly, if well, to sanction views in the prevention of disease which their fellow-countrymen have long since accepted.

THE CHOLERA EXPERIMENTS UPON ANIMALS.

THE following interesting account of some experiments which two Swiss physicians, Rietsch and Nicati, have been making in the laboratory of the Pharo Hospital at Marseilles, by instructions from the French Government, has been forwarded to us by a correspondent in Paris. They have, in addition to cultivating the cholera microbe as Dr. Koch had done in the same laboratory two months ago, and obtained thousands of microbes from the intestines of cholera patients immediately after death, inoculated a number of guinea-pigs, dogs, and rats, with the deadly disease. The success of these experiments is described by the *Journal de Genève* as complete. The guinea-pigs all died at a minimum interval of forty hours, after symptoms of diarrhœa and cramp, the same as with human beings, while the dogs mostly died four days after inoculation. The guinea-pigs were much more susceptible to the disease than any other kind of animal, and when Drs. Rietsch and Nicati injected some of the contents of a human intestine into their stomachs, they died from the self-same causes which in a similar case would kill a human being. To make the inoculation more effectual, they injected the choleraic secretions right into the duodenum, as they had observed that the bile has the effect

Digitized by Google

of checking the development of the microbe. The conclusion which they draw from these experiments is that there is a practical mode of diagnosis in all doubtful cases of cholera, and that in such cases it will be sufficient to repeat with the contents of the patient's intestine the direct inoculation into the duodenum of a guinea-pig to ascertain within a few hours whether it is a case of cholera or not. The second conclusion which they draw is a prophylactic one, and it is that the gastric juice and the bile digest the microbes very thoroughly. These two juices are excreted in large quantities during the digestion which follows a meal, whereas they are scarcely excreted at all when it is merely liquid which passes through the canal. This is equivalent to saying that impure water is less dangerous when taken with food than when drunk by itself. The mutual relations of indigestion to diarrhœa are of the same order, and they confirm in every particular the connexion between the cholera and the microbe discovered by Dr. Koch. The Swiss physicians have repeated their experiments two or three times before the staff and students of the hospital, and before several medical men from Barcelona, who had come to Marseilles for the purpose of witnessing the experiments.

HÆMORRHAGE INTO THE CORPUS CALLOSUM.

PROFESSOR W. ERB of Heidelberg records a case in which the rare event of hæmorrhage into the corpus callosum occurred (Virchow *Archiv.*, 97, 2). He remarks that physiology teaches nothing concerning the functions of this structure, and that pathological data concerning it are very scanty. For the most part these latter comprise observations of developmental defects, with corresponding psychical deficiency (Hitzig), but others (Paget, Jolly, Malinverni) have recorded cases in which the corpus callosum has been absent without any manifest mental derangement. Cases of tumours of the corpus callosum are evidenced more by the pressure signs exerted on the hemispheres than on the body itself, and instances of hæmorrhage and softening have very rarely been met with. Gintrac, among 560 cases of cerebral hæmorrhage, gives one involving the corpus callosum, but not a single case is to be found in Canstatt's Year Book from 1851 to 1882. Erb's patient was a man sixty-one years of age, who was found in a wood near Heidelberg in a state of somnolence. He had been attacked six days previously with headache, giddiness, vomiting, stiffness of the neck, and pains in the neck and legs. There was no paralysis nor ataxy; the pupils were small; vision normal; optic discs natural; the urine was albuminous. A few days after admission the rigidity of the neck became more marked, speech difficult and jerking; he moved the limbs slowly, but without tremor, and there was still no evidence of paralysis. In the absence of definite symptoms the idea of cerebral hæmorrhage was discarded, and a diagnosis of subacute cerebro-spinal meningitis suggested. As the case progressed this idea appeared confirmed by the increasing and persistent cervical rigidity, the occurrence of slight spasm of both arms and both sides of the face, frequent vomiting, delirium, and death. The post-mortem examination revealed hæmorrhage with inflammation of the pia mater over the frontal lobes, both on convexity and base, and on the temporo-sphenoidal lobe near the Sylvian fissure. There was a like hæmorrhagic infiltration of the pia mater on the posterior surface of the spinal cord, especially in the lumbar region. So that to a certain extent the diagnosis was confirmed. But in addition to these lesions the corpus callosum was found in almost its whole extent (the anterior extremity alone excepted) to be destroyed by hæmorrhagic effusion, and the lateral ventricles contained sanguinolent fluid. The fornix had disappeared, and the hæmorrhage extended into the gyrus fornicatus. There was also some extravasation into the ascending meso-colon, lobular pneumonia, cystitis and nephritis dependent on a stricture of some standing. Remarking on the occurrence of the callosal hæmorrhage, Professor Erb says it is difficult to say if it were the main cause of death, but it also cannot be said to have had no share in the issue. The corpus callosum was almost wholly destroyed, and yet the case presented no symptoms directly referable to the lesion, all the symptoms which occurred being explicable by the meningeal affection. Even if the slight dulness of intellect and slowness of speech were due to the former, these are but slight grounds from which to diagnose a lesion of the corpus callosum. The case is of value as showing that this structure may be destroyed without producing any disorder of motility, of coördination, of sensibility, of reflex action, or of the special senses, and no appreciable impairment of intelligence. It therefore tells nothing concerning the function of the main commissure of the brain, save that its integrity is not essential to those prime functions of the nervous system.

FORMIC ACID AS A GERMICIDE.

THE conditions of animal life vary immensely; the introduction of a single influence, not apparently of a powerful nature, may determine the death of some organisms. M. Schnetzler, a few weeks ago, communicated some observations to the Académie des Sciences, which serve to illustrate the above general principle. He has found that *bacterium subtile*, one of the most difficult micro-parasites to kill, dies when in the presence of formic acid. Even when this bacterium has resisted the action of boiling-water for one hour, it may be instantaneously killed by formic acid; a drop of water containing $\frac{1}{1000}$th part of formic acid, added to a drop of water teeming with thousands of the bacteria, is sufficient to effect the purpose. The swarming fluid so treated may be introduced into the digestive tract with impunity. The author recommends the trial of formic acid on the cholera bacillus, and it may be suggested that its action on bacillus anthracis is equally deserving of experiment. If formic acid should be found to be capable of destroying the dried virus of charbon, provided this chemical agent does not injure imported wool, and in such a diluted state injury seems impossible, the suggestion that all imported wool be washed in a weak solution of formic acid might be of value in preventing the occurrence of so fatal a disease as malignant pustule and its allies.

MODE OF ACTION OF VACCINATION.

PERHAPS there is no subject which presents a broader field for speculation than the question of the explanation of the effect exercised by vaccination. How does vaccination protect from small-pox? The problem is obviously equivalent to the question, How does typhus protect from typhus? Mr. F. J. Faraday read an interesting paper before the Manchester Literary and Philosophical Society dealing with this matter. It has been suggested that a certain material which is necessary for the development of the vaccine virus is elaborated in the body only rarely or at long intervals. This view is dismissed by Mr. Faraday as being too crude. Without giving our adhesion to this view we may venture to say that the mere crudeness of a theory is not in itself sufficient reason for rejecting it. The gentleman referred to appears to prefer to search for an explanation in some ill-defined "educational influence," developed in a struggle for existence between the causes of vaccinia and the living cells of the body. If we inquire into the nature of this "educational influence," we perceive that it may be expressed in terms of physiological chemistry as an altered molecular condition of protoplasm. The living cells have, so to speak, changed their front, and now are able to

Digitized by Google

resist an attack from the vaccine virus. The "resisting vigour" resulting from this education Mr. Faraday compares to the apparently instinctive movements observed by Darwin in the tips of the radicles of plants, which Mr. Faraday attributes to an "apparently muscular memory," perfected by practice. There is much foundation for the belief that in nature no experience fails to leave its impress and its influence behind. Were it not so, the difficulty of explaining the phenomena of nature would be almost insurmountable. It is true that many alterations are brought about only after repeated influences, but even then the law holds good; for it is probable that every separate influence exerts some action and produces some alteration, though we may not be able to perceive the minute change. Mr. Faraday pointed, as an illustration of his argument, to the education of smokers, who overcome the nausea caused by the first mild cigar, and educate the cells of which the smoker consists into the enjoyment of even strong Havanas. He concluded by saying that "reduced to its ultimate expression, animated nature would appear to consist of Buffon's organic (organised) molecules *plus* the principle of organic memory, as inorganic nature is inert matter *plus* the principle of motion." Viewed in the light of the principle of evolution, there can be no doubt that protoplasm can register changes which occur in its environment; indeed, this statement involves the whole doctrine of life as enunciated by Herbert Spencer. Protoplasm may be regarded as nothing more than the adjustment of internal to external relations. A living cell is an impressionable epitome of its whole past experience.

TRANSPOSITION OF VISCERA.

A CASE of transposition of the viscera, with details of the post-mortem examination, is recorded by Dr. Alfr. Richter of Dalldorf (Vichow's *Archiv*, 97, 2). The subject was a man born in 1862, who had been thrice treated in La Charité, once for syphilis, once for lung affection, when the "heterotaxy" was discovered, and on the third occasion in April, 1884, for mania, for which he was transferred to the Dalldorf Asylum, where he died. It was observed during life that the heart's impulse was in the fifth right intercostal space, between the mammillary and parasternal lines; the heart sounds were normal. On the left side hepatic dulness extended from the sixth rib to the margin of the thorax. The conditions found after death were as follows:—On opening the abdominal cavity the liver was found lying on the left side, and the heart, which was well developed, lay on the right. The right cavities contained arterial blood and were thick-walled, the auricle receiving the pulmonary veins and the auriculo-ventricular orifice being furnished with a bicuspid valve. The aorta which sprang from the right ventricle passed with the pulmonary artery over the right bronchus, and descended to the right of the spine. The venæ cavæ opened into the left auricle, which was furnished with a tricuspid valve. The right innominate vein was larger than the left; the vena azygos was on the left side; the thoracic duct opened into the right subclavian vein. The right lung had two lobes, the left three; and the right bronchus was smaller than the left. The œsophagus passed from right to left across the aorta; the stomach lay to the right, the pylorus and duodenum to the left, and the spleen to the right. The cæcum lay on the left side, the sigmoid flexure on the right. The right testicle was lower than the left; the right kidney lower than the left. The spermatic artery on each side was given off from the aorta. The writer has collected details of forty cases of transposition of organs, nineteen in the male and sixteen in the female, in five the sex not being stated. In twenty-four of these cases there are records of post-mortem examination. Nine died shortly after birth; but among twenty-two the average age attained was thirty-five years. Of the twenty-four examined after death, seventeen exhibited a complete heterotaxy, and six had further cardiac abnormalities. Among other facts he notes that left-handedness was only observed in one case. Another case of complete transposition of the viscera is recorded in *Le Progrès Médical* (Sept. 13th, 1883) by M. Leveque. The subject was a young woman, nineteen years old, who died from acute meningitis, and the condition was first observed post mortem. In every respect this case tallies with the foregoing, except as regards the pancreas and spleen. The pancreas was reduced to the size of a chestnut, and occupied the usual position of the head of this organ, but on the left side according to the altered position of the duodenum. The spleen was in two portions, each not larger than a nut. The arch of the colon lay behind the coils of small intestines, and terminated on the right in the sigmoid flexure. The renal veins passed behind the aorta, and the spinal column had a marked lateral curvature, the concavity being to the left.

DR. VANDYKE CARTER AND THE SANITARY COMMISSION OF BOMBAY.

IT is with great regret that we learn that the Government of Bombay have taken the exceptional course of reappointing their late Sanitary Commissioner for a further period of four years. The office is one of importance, and it is natural that promotion to it should be looked forward to as the legitimate reward for services rendered to sanitary science and medicine by officers in the Indian Medical Service. There is no one who has more thoroughly earned a claim to such a consideration from the hands of Government than Dr. Vandyke Carter, who has spent the best part of his life in arduous and important scientific research. Our readers may remember his contributions to such subjects as elephantiasis, chyluria, leprosy, and mycetoma, in which he ranks as a discoverer; but, perhaps, the most important and the most fruitful of all was his inquiry into the famine fever, which he proved to be identical with the relapsing fever of Europe, and the studies of the spirillum which he made in this connexion. Everyone must have felt that the British Medical Association did rightly in awarding him in 1882 the Stewart Medal for his researches in these subjects. We trust it is not too late for an act of bare justice to be rendered to Dr. Carter by nominating him to an office for which he is so thoroughly fitted. England is as well able to recognise scientific merit as Germany; but we venture to say that in that country no man of Dr. Vandyke Carter's calibre would be denied the opportunity of serving his country and enhancing his scientific reputation by a promotion, which is not only due to him for his work, but is his by right of seniority.

CHOLERA NOSTRAS.

BY no means the last word has been said respecting the organism which Dr. Koch regards as the essential factor in cholera, and doubtless the main contention will be held over its alleged pathognomonic character. Some researches lately conducted by Drs. Finkler and Prior of Bonn have been published (*Deutsch. Med. Wochenschrift*, Sept. 4th) upon cases of so-called cholera nostras which contravene the statement of Koch that the comma bacillus is not met with in that disease. The observers had taken pains to prepare themselves for the contingency of cholera coming under their notice by examining stools in dysentery, tuberculosis, and other diseases from the bacteriological standpoint. At last, in July, the opportunity arrived; a small epidemic of choleraic diarrhœa occurred in Bonn—twenty-nine cases in all, many occupying the same house. The symptoms were severe, hardly to be distinguished from those of Asiatic cholera, the stools passed in the later stages being almost colourless; but

Digitized by Google

every patient recovered. In the later evacuations large numbers of micrococci abounded, similar to those found in any case of diarrhœa from whatever cause arising. But when the stools passed in the early stages of the attack were examined, there were found, in addition to small and large micrococci and bacilli of various kinds, some comma-shaped bacilli which accorded in every particular with those described and figured by Koch. They were often found collected in small nests, and mingled with them were a large number of spirilla, which could be best detected in the dried specimens in which the bacilli took the aniline stain less markedly. No such forms were detected in normal fæces, nor in the stools from cases of typhoid, tubercular and dysenteric ulceration, infantile diarrhœa, nor in decomposing urine, mucus and other products; so that a certain specific character was imposed on them. But cultivation experiments (made on linen and on potato) were not successful in discriminating these bacilli; on the contrary, amongst all the forms which appeared in the cultures, the micrococci largely predominated. Feeding experiments upon dogs, previously given croton oil, and upon rabbits, were negative in result. The writers point out the difficulty alluded to at the Berlin Conference by Hirsch, Skreczka, and others in distinguishing clinically between endemic cholera and Asiatic, and aver that the only distinctive feature of this Bonn epidemic was its circumscribed limitation and non-fatal character. Dr. Koch had laid stress upon the detection of the comma bacillus as a means of diagnosis, for he had failed to find this organism in cholera nostras; but Drs. Finkler and Prior point out that the bacillus was only to be found in the early stages, the subsequent watery evacuations, although full of bacterial life, containing none of these special forms. It is, however, possible, they admit, that in spite of the resemblance in form between the bacillus they met with and that described by Koch, their failure to cultivate it may point to an essential biological difference.

THE DRAINAGE OF CAMBRIDGE.

THE filthy condition of the river Cam has at length drawn forth an expression of public indignation. That being the case, we may now hope that steps will be taken to remedy the disgraceful state of things that has been so long permitted to endanger the health of the undergraduates and the inhabitants. The local authorities have endeavoured to shield themselves for their past neglect by the excuse that they were unable to agree with the university authorities with regard to the rates to be paid by the town and university respectively. In 1874, when our commissioner visited the town, on the occasion of the outbreak of typhoid fever at Caius College, it was stated that an Act was in preparation applying for powers to settle this question and proceed with a drainage the ensuing year. Ten years, however, have elapsed since then, and still matters remain *in statu quo*. We are pleased to see, however, that the Local Government Board have at length expressed an opinion that the authorities are not justified in postponing the necessary works pending the settlement of the rating question between the university and the town. There, is, however, another question connected with the sanitary arrangements of the university, and that is the more efficient inspection of the undergraduate lodging-houses. Many of these are in a very unsatisfactory state as regards their interior sanitary arrangements and house drainage; whilst, owing to the imperfect discharge from the main sewers, dangerous accumulations of sewer-gas and even sewage are apt to occur. To guard against the ill-effects of this, special attention ought to be paid to domestic sanitation; yet at Cambridge, now one of the largest medical schools in the kingdom and a university granting a special certificate in sanitary science, the sanitary inspection of the lodging-houses is conducted by a clergyman! Certainly in this respect they manage things better at Oxford, where all the lodging-houses are inspected by a properly qualified sanitary official before being licensed, and are visited during term time to see that all is working efficiently.

EVENING RISE OF BODY TEMPERATURE.

THE daily variation of the temperature of the body is a fact which has not yet been satisfactorily accounted for. Dr. Ringer has observed (*Proc. Roy. Soc.*, xvii., p. 287) a diurnal variation, independent of food or other circumstances, the maximum temperature ranging from 9 A.M. to 6 P.M., and the minimum from 11 P.M. to 3 A.M. M. Maurel recently read a paper before the Académie de Médecine, in which he sought to establish the dominant influence of food in the production of the evening rise of temperature. Light, motion, and alimentation have been investigated in this connexion. By feeding animals during the night and causing them to fast during the day, M. Maurel states he has been able to make the maximum temperature appear at any hour he chooses. The experiments must be prolonged over several days in order to obtain the results. This condition would probably be explained on the principle of habit; and although the term "habit" may be classed as a question-begging epithet, there yet does appear to be something of a true explanation in it. For instance, a patient becomes the subject of a catarrhal affection of the bowels attended with diarrhœa; it is well known that after the disappearance of the signs of catarrh there is a looseness of the bowels to be dealt with, which looseness may perhaps be best explained on the hypothesis of a "habit" of the musculo-nervous apparatus of the intestines. Many other examples readily suggest themselves. The influence of light and movement were found by M. Maurel to have an altogether secondary influence on the temperature of the body.

INSECT LIFE AS A CAUSE OF DISEASE.

THE defenders of the germ theory of cholera may be interested to refer to the able essay "On the Hypothesis of Insect Life as a Cause of Disease," which was published by Dr. (afterwards Sir Henry) Holland in 1839, in his "Medical Notes and Reflections." After recalling the researches of Nyander on the exanthemata viva, the author proceeds to discuss the question, "What weight may we attach to the opinion that certain diseases, and especially some of epidemic and contagious kind, are derived from minute forms of animal life existing in the atmosphere under particular circumstances, and capable, by application to the lining membranes, or other parts, of acting as a virus on the human body?" The arguments, which Dr. Holland advanced in reply, led him to the conclusion that Asiatic or epidemic cholera is a disorder so peculiar in its nature, and spread over the globe in a manner so remarkable, as not to be referable to gaseous, mineral, or vegetable matter diffused in the atmosphere or exhaling from the earth. He deemed equally inapplicable every theory of causation founded on the temperaments, habits, food, or other conditions of particular communities. The hypothesis, which found most favour with Dr. Holland, is that "which looks to animalcule life, diffused by the atmosphere or by man, as the source of the disease;—a form of life not recognisable by our senses, or other direct means of research, but nevertheless subject to some similar laws of propagation and diffusion as species more obvious to us, and producing a virus which acts noxiously on the human body." The author foresaw that his theory, if justified by experience, must of necessity extend to certain other contagia; and the able essay not only foreshadows, on the basis of analogy and circumstantial

Digitized by Google

evidence, the researches of Pacini and Koch on the cholera bacillus, but is rich in suggestiveness on the wider subject—the germ theory of disease.

TETANUS PRODUCED BY HYPODERMIC INJECTIONS.

DR. PIETRO ROSSI reports in the *Gazzetta degli Ospitali* (7th inst.) a case in which tetanus followed repeated injections of hydrochlorate of quinine. The patient was a youth aged eighteen, of lymphatic temperament, affected with incipient pulmonary tuberculosis. Hydrochlorate of quinine was injected every other day, sometimes twice a day, with much constitutional benefit; but each puncture was followed by slight local irritation, with circumscribed redness and pain under pressure. These symptoms only lasted a day or two. In consequence of febrile exacerbation, the injections were repeated twice a day for three days, alternately in the arm and forearm of the same side. Each time the solution of hydrochlorate of quinine was the same in strength, bulk, and temperature. Four days after the last injection the pain increased at one of the punctures, which became red and turgid. These symptoms were allayed by repeated poultices, and no fever supervened; but the patient complained of great weakness, and of difficulty in moving the jaws when eating. Chloral was at once freely administered by the mouth; but in the course of a few hours all the symptoms of tetanus were developed—trismus, opisthotonos, and pharyngeal constriction, preventing deglutition. Chloral clysters in large doses proved unavailing. Muscular spasms of the trunk increased in frequency and violence, and death occurred suddenly, thirty hours after the appearance of the first tetanic symptoms.

THE RECENT ILLNESS OF MISS ELLEN TERRY.

MISS TERRY is on the eve of departure for a second American tour with Mr. Irving and his company. While we are pleased to be able to state that she is now on a fair way to complete recovery, it may be well to explain that her illness was not due to vaccination, as was popularly supposed. She had been successfully vaccinated on the *left* arm by Mr. George Stoker ten days previously to the appearance of a whitlow on the right thumb. In spite of this, and the warnings of Dr. Fenton Jones, who attended her in this illness, she persisted in going through the fencing scene in Twelfth Night. The inflammation, however, crept up into the forearm, all the flexor tendons becoming very rapidly involved. The thumb was twice lanced and deep suppuration for some time threatened about the wrist-joint. Mr. Jonathan Hutchinson saw the case several times in consultion with Dr. Fenton Jones.

MELANURIA.

AMONGST some of the most interesting phenomena of physiological chemistry are the conditions of the urine as regards its coloured constituents. As is well known, the pigments of urine are not all visible when that fluid is first passed—e.g., the presence of indican requires chemical manipulation for its detection. Zeller has recently observed a rare case of melanuria in a man aged forty-three, who was the subject of multiple melanotic sarcomata of the skin, and who died six weeks after he was admitted to the hospital, of cerebral complications. The urine was of a brownish-yellow colour, absolutely clear, of a density of 1020-1030, free from sugar or albumen. Chemical analysis showed a slight increase in the amount of sulphuric acid discharged; phenol and indican were of normal proportions, but the quantity of hydrobilirubin was largely augmented. There existed a constant relation between the black colouring matter and the bilirubin in the sense that when the urine was light coloured the more urobilin it contained, and the less melanin it had; the darker the urine the more melanin it yielded, and the less urobilin. Bromine water gave an abundant precipitate, yellowish and amorphous, but on resting this changed spontaneously to black. The test with bromine proved to be more sensitive than that obtained with nitric acid or chromate of potash. The precipitate of bromomelanin appeared in the dry state as a brilliant black solid which became a brown powder when triturated. The bromine reaction distinguishes melanin from urobilin, which gives with bromine water a yellow precipitate, not, however, passing into black when left to stand; so that normal and febrile urines do not give the black precipitate when treated with bromine water. Zeller believes that the urinary pigments proceed from two sources, the one being the colouring matter of the bile or blood, and the other aromatic substances developed in the intestine during the process of digestion of albuminoids. It is probable from his observations that melanin is derived from the latter source, though the want of further investigation is admitted.

EXPERIMENTAL TYPHOID FEVER.

SOME interesting observations on the natural history of the typhoid fever poison have been made by M. Tayon and communicated by him to the French Academy. It appears that neither blood nor excreta when taken from a typhoid patient is capable of conveying the infection of that disease when directly injected into one of the lower animals. But if the blood be added to sterilised broth, a turbidity results in about twenty-four hours, due to the development of multitudes of microbes, and the liquid is then capable of inducing typhoid lesions in a guinea-pig, causing death in periods ranging between twenty-five minutes and forty-five hours, and to a less virulent degree in sheep, dogs, and cats. Pigeons, doves, rabbits, and white rats, however, are refractory to this liquid, though in transmission through a guinea-pig the microbes appear to acquire an increased virulence, and are then capable of producing fatal typhoid in cats, sheep, and chickens, after which stage rabbits also are susceptible to the influence of the poison; but in every case an intermediate cultivation is necessary. A guinea-pig inoculated from another guinea-pig produces nothing; whereas if the inoculating fluid be artificially cultivated for twenty-four hours the inoculation is successful. It would appear, therefore, that typhoid germs, which when magnified one thousand diameters appear as small granules or very mobile short rods, unlike the organisms peculiar to charbon, require an alternation of surrounding conditions for their development, resembling in this respect certain intestinal worms.

THE ETHICS OF CANNIBALISM.

THE *New York Medical Record* of Aug. 23rd contains an article on the rescue of Lieut. Greely, and all the questions raised by the ill-fated expedition of which he was the chief. The article has the more interest for being written by one who has had an interview with Lieut. Greely. Alcohol, in the form of whisky, rum, &c., was regarded as of little benefit against cold, or for bracing the system for forced marches. According to the lieutenant, the healthy European or American, with plenty of food, can resist the cold of the Polar regions for a limited time; but each successive winter would witness a rapid deterioration of nervous and muscular energy. With inadequate supplies of food, inducing the condition of *chronic* starvation, the dilapidation of the mental and moral functions comes on apace, involving irresponsibility, in the writer's opinion, and the excuse, if not even the justification, of cannibalism. It is important to remember that he assumes the death of the persons whose

Digitized by Google

flesh was eaten. When this is assumed, and the practical insanity and consequent irresponsibility of the cannibal is further assumed, there is not much to debate; but the multiplying adventures of an age of quickened activity remind us that it is no light matter in a journal of any authority to find excuses for a practice that has been hitherto the monopoly of the lowest savages. The courts of England will soon have to decide on the conduct of those who, in any extremity, tamper with the feeblest or meanest human life to save their own.

NON-PAYING PATIENTS AT ST. THOMAS'S HOSPITAL.

No ingenuity of statement ought to blind the public to the fact that hospitals, especially endowed hospitals, are for the poor, and for the gratuitous treatment of the poor in the day of their trouble. That St. Thomas's Hospital is obliged to receive pay-patients into some of its wards is true. The more is the pity, and the more the discredit to its past governors. We have no sympathy with the notion that those who live on small wages and in straitened homes ought to pay petty sums for lodging and treatment in our great hospitals. The rich and the poor need to cultivate each other's affection and respect. It will be hard on the rich to deny them the pleasure of providing for the poor man a bed in a hospital when laid aside from work by a grave accident or a graver disease; it will be harder on the poor to make them pay. We are quite of opinion that the working classes *en masse* should give much more to the hospitals than they do. They are rapidly coming to see that they have not done what they might have accomplished by a little systematic contribution at their places of employment. Witness the instance of Messrs. J. S. Fry and Sons, whose employés readily agreed to the deduction of 1*d.* per week from their wages, resulting in a subscription for the half-year of £106 13*s.* 11*d.* But we protest against petty charges to poor people for hospital accommodation. By all means let them pay systematically and in a provident way for ordinary sickness, but for great calamities—and nobody knows but the uncomplaining poor what dire calamities, great accidents, and great diseases are—we hope the day is far distant when English charity will refuse to provide hospitals and dispensaries. They must be either destitute of heart or of imagination who cannot see, that even with 20*s.* or 30*s.* a week, and where work is pretty constant, there is nothing to raise a man above the need of the pity and the help of his richer and more fortunate neighbours.

ELECTROLYSIS OF THE EUSTACHIAN TUBE.

DR. BARTOUX (*Progrès Médical*, August 30th), writing on electrolysis of the Eustachian tubes, commences by enunciating the general principle of chemical galvano-caustics. When an imperfect conductor in conditions of cohesion facilitating its decomposition is placed in the circuit of a pile with sufficient electro-motor power, that body is decomposed; the acid goes to the positive, the alkali to the negative electrode. When the electrodes cannot be attacked, and the interfering substance is of organic nature, the nascent acids and alkalies act on the tissues as potential caustics, and produce an eschar exactly coextensive with the points of contact of the electrodes. In the majority of contractions of the Eustachian tube, due to swelling of the mucous membrane, the author admits that dilatation with elastic bougies is sufficient. But when it fails after being employed a sufficient length of time, he advises resort to chemical galvano-cauterisation. He likewise recommends it when the entrance to the tube is obstructed by hypertrophied lymphatic follicles, and in the comparatively rare cases of membranous bands. He adds that when it is desired to perforate the tympanum, this may be done by affixing one or more needles to the negative pole, and placing the positive one as a metallic plate on the mastoid process, or as a roll of carbon covered with chamois leather held in the hand.

THE INDIAN CHOLERA COMMISSION.

THE recent appointment of Dr. D. D. Cunningham to the important Indian Cholera Commission does not seem to have given entire satisfaction to the officers of the Indian Medical Service. It appears that Dr. D. D. Cunningham has expressed strong anti-contagionist views, and, moreover, by having caused certain sanitary commissioners and medical officers who have ventured to express views contrary to this doctrine to feel the weight of departmental displeasure; it is therefore thought that one so strongly biased can hardly approach the question in a scientific spirit. However that may be, we are somewhat surprised that the Commission contains no other names that would have weight at home. We do not speak of the younger men, those who have distinguished themselves recently at home, who have left England with a high prestige, and whose knowledge of recent pathological methods of research under the guidance of some well-known senior would have proved invaluable, but we speak of men who are of European as well as Indian reputation; for instance, Dr. Vandyke Carter or Surgeon-General Cornish. Certainly, whoever is appointed ought to be free from all previously expressed bias; and although Dr. D. D. Cunningham undoubtedly holds a distinguished position in India, still the reports he has issued, make it doubtful in the opinion of many of the Indian medical officers whether he is the best fitted for the appointment, or, if appointed, whether he should not have been associated with others whose views have been less strongly expressed.

WHY TROPICAL MAN IS DARK.

AN interesting communication has been made to *Nature* by Surgeon-Major Alcock on the reason why tropical man is black. The eyes of many of the lowest animals are generally to be descried by means of the patches of pigment which form their most conspicuous element. It is suggested that pigment placed behind a transparent sensory surface, such as the eye, increases the stimulating effect of rays of light. The well-known absorbent power of dull black things for heat, and the increased activity of all living matter under the influence of warmth, are points bearing on this question. In the negro the pigment-cells are placed in front of the nerve terminations, and here the black pigment in the skin serves to lessen the intensity of the nerve-vibrations that would be caused in a naked human body by exposure to a tropical sun; so that the pigment plays the same part as a piece of smoked glass held between the sun and the eye. The reasoning by which pigment, like the breath in the fable, is made to play the part of hot and cold, does not seem to be perfectly free from objection; but the speculation must be admitted to be interesting.

"TEXAN FEVER" IN BIRKENHEAD.

AN interesting question in regard to cattle disease has been left undecided in the Birkenhead police-court. Two American cattle suffering from Texan fever were slaughtered, and an application to have them destroyed was disputed by the owners. The post-mortem appearances were the following:—The meat was dark-coloured, and, according to one witness, jaundiced; the spleen was tumid and engorged, and weighed about seven pounds; the liver in one case was considerably enlarged, and the heart in both showed patches of extravasated blood upon the surface; the lungs were engorged, and the kidneys of a dark copper colour. The de-

Digitized by Google

fence rested mainly on the fact that the muscular substance itself could not be said to be decidedly altered, and on the absence of gross lesions in the viscera. It was alleged that such meat, if properly cooked, might be eaten with impunity. The evidence as a whole clearly indicates the presence of disease, and the lesions, both in position and in character, are those of a general fever which has not reached the stage of advanced inflammation. Some of the features are strongly suggestive of anthrax, and the association of high temperature with local extravasation of blood reminds one forcibly of the similar connexion which has been demonstrated of late in the pathology of various septic fevers. It is to be hoped that the present uncertainty will be conclusively settled by the impartial investigation which it is proposed to institute in the next similar case which may present itself, and that skilled experimenters may be obtained for this purpose. Meantime, it certainly seems unwise to expose the meat of such animals for sale, protected only by the doubtful safeguard of a recommendation to cook it well.

THE DISUSED BURIAL-GROUND OF PADDINGTON GREEN.

THE action of the parish authorities at Paddington, in laying out the long-disused burial-ground of Paddington-green for purposes of recreation, appears to be in itself a movement in the right direction. Unfortunately its value as a sanitary measure is greatly marred by other plans and circumstances which are associated with it. A part of the same ground is already occupied by a mortuary, the position of which, even as it now stands, is not entirely free from objection, since it is in close proximity to an iron church, and abuts upon houses in the most populous part of the district. It is proposed, moreover, to enlarge the mortuary, and also to erect an additional building for the reception of infectious cases which may be subject to inquest. This, taken by itself, is no doubt an excellent measure. It evidently aims at obtaining for certain dangerous diseases, as distinguished from other causes of death, especial care in isolation and disinfection. No complaint could be brought against it if the surroundings were appropriate; but they are not. One readily sees that at any time when such diseases were prevalent, frequenters of the adjacent pleasure garden who might be near the mortuary would run considerable risk from infection. In fact, the piece work of the vestry's plan is good, but its combination into a whole, and the relations of that whole, constitute its danger. The difficulty can only be met by either surrendering the project of a recreation ground or of the mortuary additions, or, on the other hand, by enclosing with the latter a piece of vacant land sufficient for their complete isolation, and having no communication by common entrance or otherwise with the area devoted to the enjoyment of the public.

COMPULSORY NOTIFICATION AT DUNDEE.

ACCORDING to Dr. Anderson, medical officer of health for Dundee, the system of notification of infectious diseases in that burgh has proved an unqualified success. The Local Act requires notification both by the householder and the medical attendant. Where that is the case in England, sanitary authorities rarely take any steps to enforce it in so far as the householder is concerned, provided they get the information from the medical attendant. In Dundee, the absence of all friction and complaint, and the almost total absence of concealment, is stated to be due to the fact that the sanitary department strictly exact from every householder the fulfilment of his legal obligation to report, and that often independently of the medical attendant's report; and it is consequently felt that when the householder himself is bound to notify the presence of infection in his household, he can have no ground of complaint because his medical attendant does so also. During 1883 the system of notification revealed two outbreaks of infectious disease in connexion with milk distribution. One was scarlet fever among the customers of a dairyman who did not at the first onset report the disease in his house, but the information came soon enough to prevent a wide outbreak. The next was a wide diffusion of enteric fever, and the magnitude which the outbreak might have assumed may be judged of by the fact that, although, owing to the system of notification, it was absolutely stamped out in twenty-two days, yet it occasioned 132 cases. But for some obscurity as to its origin it would not have lasted even twenty-two days.

DEATH FROM STARVATION IN LONDON.

THE circumstances of the death of Elizabeth Blackwell, investigated by Mr. A. Braxton Hicks, the deputy coroner for Westminster, are very painful reading. Of course she should have gone into the workhouse before starvation did its deadly business and produced that pitiful picture of a woman, sixty years old, too self-respectful to admit her want, honest in paying her way, and then found lying dead on her back on the floor, perfectly naked, with the exception of an old boot on the right foot, in a room which contained not a piece of furniture, but an old jacket, a shirt, and a few pieces of stale bread, fragments of meat and potatoes, "which had evidently been picked up in the gutter," and close by her head an old Bible. No doubt she died dreaming of the City where "they hunger no more." Who is to blame that she did not find this in London with its four millions of Christians? We commend the picture to Mr. Arthur Stocks or some other man in whom Art and human pitifulness meet, that it may stare us in the face till London answers to the description of the Apocalypse.

THE HOSPITALS AND THE HEALTH EXHIBITION.

IT is gratifying to know that his Royal Highness the Prince of Wales has been able to hand over £4000 to the Lord Mayor for distribution among the hospitals of London. The Lord Mayor is, *ex officio*, President of the Hospital Sunday Fund, and it is not unlikely that his Lordship may hand over the amount to be dealt with at the discretion of the Council of that fund. We are still more concerned to know how the Council of the Health Exhibition will deal with the considerable surplus of profit that is likely to accrue to them, and we repeat the expression of our strong conviction that amongst the main purposes to which it should be applied is the foundation of a bacteriological museum and the further assistance of our noble but starved hospitals.

ANILINE COLOURS.

THE prominence which has lately been given in the daily papers to the hurtful properties of aniline dyes in many of their applications is not due to the fact that those properties have now for the first time been demonstrated. Ever since the name of magenta has been known to commerce there have been cases of local inflammation from wearing it or one of its allied colours on clothing next the skin. Distrust of all textile materials stained in this way has consequently long existed among intelligent people. The position in the market which goods thus coloured still hold must be greatly due to the diversity of aniline hues, which enables the compounds of that substance to mimic, while they seem to surpass in finish, the stable and innocuous dyes obtained from various vegetable juices. Fortunately public taste is shrewd enough to perceive that permanence is a point of value in respect of colours as of other things. The same quality affords the most reliable common test that any given

Digitized by Google

colour is a safe one for daily wear. Those whose means and education enable them to discriminate, and purchase accordingly, run comparatively little risk. Many of the poor are less happily circumstanced in both these particulars. Upon their children it is not unusual to meet with some highly-coloured garment, and to find that the dye disappears in a washing or two. Aniline stained confectionery forms another of their inexpensive pleasures. It cannot be too strongly insisted on that indulgence in either form is purchased at the risk, and often at the price of health, and it may be hoped that recent cases of aniline poisoning will impress this truth.

MACARONI AND CHOLERA.

ITALIAN macaroni, which is largely manufactured at Naples among other places, has become a subject of some animadversion since the marked prevalence of cholera in that city. The alarm of infection is probably in this case not very well founded. Macaroni is in a great measure prevented from acting as a vehicle of this disease by certain valid considerations. The simplicity of its composition is one of its safeguards. Consisting essentially of flour and water, it is open to infection only through the latter of these ingredients, and that under the special condition of a cholera-tainted water-supply, which, so far as we know, has not been shown to exist in Naples. Again, the dryness of this article of diet is sufficient to secure it against acting as an infective agent. The researches of Dr. Koch have proved one point in particular in regard to the causation of cholera—namely, the ease with which the germ which produces it can be destroyed by the mere drying up of its surrounding medium. Without moisture there can be no cholera. Add to these considerations the fact that every choleraic symptom receives in Naples a degree of attention amounting to scare, and that port officials in other countries are on the alert with regard to all Italian produce, and there does not seem to be much reason to fear the transmission of cholera in the way which has been suggested.

THE IRISH PRISONS.

THOUGH the more abundantly Mr. Gladstone labours for Ireland the less he seems to be thanked by her, we are sure that he will find a case in the report of the Royal Commission on Irish Prisons for his strong personal attention. The chiefs of the prison department are on such bad terms as to have no communication with each other except in writing. The prisons are not up to the modern standard; their cost is very great; large numbers of prisoners become insane; inspection is mainly imaginary, &c. These are grave charges, and must be immediately regarded or refuted by the Irish government. But Mr. Gladstone is sure to concern himself about a state of affairs so unsatisfactory.

CRICKET AND SMOKE.

AMONG the defunct clubs of London were some constituted on a curious application of the principle that birds of a feather flock together. There were clubs for men with bald heads, without noses, and with wooden legs. This idea seems to be in process of revival with a new and strange purpose. Cricket is played by smokers against non-smokers, as the war of tennis is wont to be waged by the married against the single. Obviously no more significance attaches to these groupings than would belong to matches in which players with three hundred a year were pitted against players with incomes below a hundred. The notion that tobacco smoking—unless it be in such excess as to produce toxic effects—can affect the power to play cricket is absurd on the face of it. At the same time, the "movement" will not be without its value if it should act as an incentive to boys to postpone the indulgence in tobacco-smoking until they attain to years of discretion. There is nothing more ridiculous than to see mere children with pipes in their mouths. If boys must smoke, let it be short lengths of cane, as was the wont—albeit with great self-sacrifice in the matter of nausea—among youths of the last generation. Tobacco smoking has its uses, as all but its most reckless censors must concede, but to growing boys it is not useful; indeed, in the majority of instances, it is injurious.

INTERMITTENT PULSE.

THE July number of the *Asclepiad* contains a paper by the editor, Dr. B. W. Richardson, on Intermittent Pulse as a Sign of Disease, and its Treatment. The paper is most interesting and practical—in many respects a model paper in practical medicine,—written in way of supplement to a former essay on this subject by the author in 1868. Dr. Richardson, in charging our predecessors with ignoring this symptom and its significance, has forgotten one classical paper, that of Heberden, "Remarks on the Pulse," read at the College of Physicians on July 7th, 1768, in which very much the same views of the significance of this symptom are expressed as those so ably and lucidly set forth by Dr. Richardson. Dr. Richardson's great contentions are that this symptom, in moderate degree, is not of grave import, and may continue over many years without much harm; and that it is purely of nervous origin, "always induced, where it is not inherited, by shocks upon the vital or sympathetic nervous system. Though sometimes associated with organic disease of the heart, it has no necessary connexion with such disease." Most practitioners of experience will agree that in its milder developments this symptom by itself is neither infrequent nor of very grave import. We have known it to be noticeable over nearly thirty years of advanced life without harm. Heberden says: "Some books speak of intermitting pulses as dangerous signs, but, I think, without reason, for such trivial causes will occasion them that they are not worth regarding in any illness, unless joined with other bad signs of more moment." Dr. Richardson's views of treatment should be read with care, and are in the main to be approved. He commends rest, sleep, and good food. The main treatment should be of a supporting character. He tries to be just to the use of alcohol in such states, and he is actually generous in his attitude towards tobacco. Moreover, he lauds opium in extreme forms of intermittency to allay nervous excitement, &c. We are not quite so convinced as he as to the fitness of opium in cases of intermittency where pain has not to be considered; but his views on this point and on the whole question should be studied by every practitioner.

A MANSION HOUSE CHOLERA FUND FOR NAPLES.

WE are glad to read that the Lord Mayor has issued a timely appeal to the charitable on behalf of cholera-stricken Naples. We have no doubt but that it will be speedily and adequately responded to, for in truth it is greatly to the credit of much-maligned human nature that whenever any grievous calamity or catastrophe occurs, willing and immediate help is always forthcoming. In this particular case the claims of sympathy are strengthened by admiration of a king's courage and devotion to his distressed people. It is difficult to limit the amount of good effected by the magnificent example of calm courage shown by his Majesty the King of Italy. When the history of our day comes to be written, the name of King Humbert will assuredly occupy a niche in the temple of fame as that of a hero who did his duty promptly and fearlessly, and was truly the father of his country.

SCURVY FROM ALCOHOLISM.

THE usual conditions under which the scorbutic diathesis is developed are amongst the commonplace knowledge of medicine. Not so, however, is it when we come to consider the intimate pathology of this affection. What the precise antecedents are has up to the present remained obscure. We think it will be granted that some constitutions are more prone to scurvy than others; but whether these constitutions are simply feeble, or more peculiarly altered from what may be termed the normal, is open to doubt. M. Masy, writing recently in the *Journal de Médecine de Bruxelles*, has put on record a sporadic case of scurvy which is alleged to have been due to the abuse of alcohol. The patient was a boy aged thirteen, living under excellent hygienic and dietetic conditions. All the signs of scorbutus were present: the gums were swollen and ulcerated, there were ecchymoses in the limbs and trunk, frequent epistaxis, hæmoptysis, cephalalgia, pains in the limbs and cachexia, leading to death in about three months from the onset of the first symptoms. The youth had early acquired the habit of drinking, and had, on first being seen, just finished a voyage of fifteen days, during which, it is said, he lived on nothing but alcoholic liquors. According to Masy, the alcohol had determined a general "steatosis" of the circulatory system, which fatty degeneration had led to all the symptoms of scurvy. In considering this case, it appears to us that while assigning a significant part in the disease to alcohol, M. Masy has overlooked the negative antecedents—viz., the absence of proper food during, on his own showing, at least fifteen days.

PUTRID FISH.

IT is not surprising that so delicate a food as fish should sometimes become stale in warm weather before any change is noticed, and in spite of care. No such excuse can be urged in the case of a dealer recently convicted at Sheffield of keeping for sale a large quantity of kippered herrings in an utterly putrid condition. Matters were so bad that the shop itself was becoming a nuisance. The fine of £25 which was inflicted may help to persuade all like-minded salesmen that honest profits, if moderate, are still the safest. The judgment in this case is the more important because of the comparative difficulty which attends the detection of fraud on the part of small dealers on their own premises and away from the regular inspection of the market officials. It is also noteworthy, in connexion with a recent prevalence of diarrhœa in Sheffield. The share of fish and, generally, of other than vegetable substances in a putrescent state, in producing diarrhœa, is apt to be underrated. It should not be forgotten, particularly by the poor, who consume large quantities of fish as a cheap form of solid nourishment, that whether cured or "wet," it requires as careful selection as more perishable fruit and vegetables.

ANOMALIES OF DEVELOPMENT AND TUMOURS.

THE interest attaching to any of the relationships of tumours has been well exemplified in an excellent paper contributed to the current number of the *Lyon Médical*. M. Pollosson has recorded four examples of the co-existence of tumours with congenital malformations. The first instance related to a cystic tumour, associated with incomplete development of the structures formed by the branchial arches, the malformations being excentric hypertrophy of the lower jaw and atrophy of the tongue. The second and third cases present the coincidence of arrest in the growth of the long bones and the development of cartilaginous tumours of the digits. These examples furnish an argument in favour of the hypothesis that enchondromata of the extremities are due to a vice in the development of osseous tissue. The fourth case consisted in the co-existence of a congenital lesion of the lymphatic tissues and lymphadenosis, which led to the death of the patient. The congenital lesion of the lymphatics was inferred from the presence of elephantiasis of the right half of the body dating from birth; at the age of twenty-one the malignant lymphadenomatous tumours made their appearance. The details of the case are promised for a later publication.

ENTERIC FEVER AT KIDDERMINSTER.

A SERIOUS epidemic of enteric fever has occurred at Kidderminster, the attacks already falling not far short of 200. By some it is attributed to defective sewer ventilation. This is denied by the borough engineer, who assails the filthy midden system. But a sudden outbreak such as this has been, and one attacking all classes of the community irrespective of social status and locality, has a strong resemblance to a water or milk epidemic. With regard to water we are assured that the town water has successfully stood the test of chemical analysis. Unfortunately the negative evidence of a chemical analysis goes for little, or nothing, when the question of infection is under investigation, and, as is now well known, water to which the medical officer of the Local Government Board had deliberately added a filtrate of typhoid stools was returned by the chemist as ranking amongst those which are of the highest organic purity. Besides which, a pollution which ten days ago might have been responsible for an epidemic may no longer be in operation when the disease appears. What is wanted to be known is whether the wells from which the town supply is derived are in any way subject to the risk of pollution.

THE ANTI-VACCINATION DEMONSTRATION.

THE foolish will do foolishly, and anti-vaccinationists will glory in their shame. It is one of the inconveniences of a free country that people are allowed to make a public display of the fact that nature has not endowed them with sense. The liberty to have small-pox is a form of liberty that we do not care for, and that we object to people possessing as being highly dangerous to their neighbours. The anti-vaccination orator entirely misses the mark when he abuses the medical profession on account of the Vaccination Laws, as if they were made for the good of medical men. The interests of the profession would be best served by the abolition of vaccination, which would ensure 90 per cent. of the population having long illnesses from small-pox.

THE POLITICAL ATHLETE.

CRICKETERS and bicyclists and boatmen may flatter themselves that they are the athletes of the day, but they are merely rejoicing in their youth. The true athlete of the time is Mr. Gladstone. Whether we regard the physical labour through which he passes, the mental strain which he bears so bravely, or the easy way in which he holds the prize of the first place against all assaults, we must accord him the first place in pure athleticism. The nation has seen nothing like it since the days of Palmerston, whose octogenarian youthfulness excited its admiration. Mr. Gladstone "has fewer years" than Palmerston had when he reached the height of his popularity and power, but his energy is faster and more remarkable. He has not the gay and light mind, the *bonhomie*, that was so characteristic of Palmerston. He is a grave man; he works harder at the great problems of State, of political and international morals, of economics, than Palmerston ever did. Twenty years ago his gravity of nature furrowed his face with care, and

Digitized by Google

thought in a way that made men doubt whether he would ever succeed to the highest place. And what things have happened since then! What responsibilities he has accepted! What must be the strength of a man who at seventy-five, in spite of such foes and forces and even failures, can hold the prize of the political game as he holds it! We are speaking apart from all political questions and issues; we are speaking from a physiological standpoint, and we pronounce the physical and mental power displayed by Mr. Gladstone in the last fortnight in Scotland, after five years of scarcely paralleled labour, to be a piece of veritable athleticism worthy the study of young men, and a fit subject of pride to the nation.

PERFECT FILTERS.

THE excellent idea of turning to account for sanitary purposes the simple method used by M. Pasteur for separating microbes from their medium of culture has suggested itself to M. Chamberlan. He finds that even the most impure water, after filtration through a porous porcelain tube, is perfectly freed from germs and microbes. Under a pressure of two atmospheres twenty litres of water per day can be obtained from a tube ·20 metre in length and ·025 metre in diameter. Tubes so used can be cleaned by plunging them in boiling water or heating them in a flame till the organic matter coating the exterior is destroyed. He proposes, therefore, that porous porcelain vessels should be used as filtering media, the external surface being exposed to the impure water.

OSSEOUS SUTURE FOR FRACTURED PATELLA.

ON this subject, Professor L. Gosselin expresses himself, in the August number of the *Archives Générales de Médecine*, in the following terms:—"In his thesis on the treatment of transverse fractures of the patella, by arthrotomy and osseous suture, M. Diverneresse has published the following statistics: Eighty-eight cases, with five deaths; two suppurations, followed by amputation of the thigh; fifteen suppurations, followed by anchylosis. It is irrational to follow a plan yielding such results in treating an injury which, under good and patient management, is unattended with any such consequences."

OPEN SPACES IN LONDON.

IT is, perhaps, not yet too late to remind both the Ecclesiastical Commissioners and the Metropolitan Board of Works that one of their most urgent duties, considering the present portentous growth of London, is to preserve, and, if necessary, to restore, at whatever cost, open spaces. Both of these authorities will deserve the gratitude of their contemporaries and of posterity by realising this part of their duty, which we take leave to say is in the greatest danger of being overlooked, with disastrous consequences.

THE HOSPITAL SATURDAY FUND.

IT is too soon to know the success of the present collection as a whole, but we may express our satisfaction at the street collection, exceeding by £500—£2800 against £2300—that of last year, in spite of the wetness of the weather. With the exception of a systematised weekly contribution, noticed elsewhere, the sums from manufactories, &c., seem to us still inadequate.

ACCORDING to MM. Treille and Straus, the comma bacillus is not special to cholera, for they have found the same bacillus in the dejecta of patients suffering from the diarrhœa of Cochinchina, or, rather, the diarrhœa of hot countries.

THE Local Government Board have issued fresh orders as to the importation of rags. One renews the previous order for France, and makes it applicable to the end of this month, and an order for Italy applies for the same period. As yet no such order has been issued as regards Spain. Under these orders sanitary authorities or their authorised officers can require the disinfection or destruction of any rags which it is desired to land, unless satisfactory evidence is forthcoming that they have not arrived from an infected locality. They can also refuse to allow the rags to be landed at all.

MESSRS. CROOKES, ODLING, and TIDY, reporting to Colonel Sir Francis Bolton, official water examiner for the metropolis, on the composition and quality of daily samples of the water supplied to London during August, state that of the 168 samples derived from the seven mains of the metropolitan water companies taking their supply from the Thames and the Lea "the whole were, without exception, clear, bright, and well filtered."

THE Ophthalmological Congress, which had been appointed to meet in Turin from the 15th to the 20th inst., has been deferred for the present, in consequence of the deplorable insanitary conditions of the Italian peninsula.

THE death is announced of Mr. J. J. Woodward, Surgeon, United States Army, the well-known microscopist.

A MEMORANDUM ON THE

"COMMA-SHAPED BACILLUS," ALLEGED TO BE THE CAUSE OF CHOLERA.

BY SURGEON-MAJOR TIMOTHY RICHARDS LEWIS, M.B.,
ASSISTANT PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL.

WITH a view of studying the phase which the cholera question has now entered upon, in consequence of the publication of the results of the investigations of the German Cholera Commission in Egypt and India, I availed myself of the opportunity which the present vacation at the Army Medical School afforded of proceeding to Marseilles, where the disease has been prevalent since the end of June. Sir Joseph Fayrer was so kind as to enlist for me the valuable assistance of Dr. Le Roy de Méricourt, Médecin en Chef of the French Navy, who, in various ways, did his utmost to further my wishes. Dr. Marroin, the Chief of the Sanitary Department in Marseilles, was so good as to introduce me to the authorities of the Pharo Hospital, where the cholera cases are treated, and where, with the permission of the principal medical officer, Dr. Trastour, I was able to renew my acquaintance with the disease, and to collect material for studying afresh the microscopy of the intestinal discharges.

Before, however, referring to the results of my own observations, it will be convenient to epitomise the published history of the German Commission; to point out the salient features of the results of their investigations in Egypt and in India; and to make a few brief comments on such of the circumstances and conclusions as appear to call for notice. Shortly after the arrival of the Commission in Egypt, Dr. Robert Koch reported, on behalf of himself and his colleagues, that no special micro-parasites had been discovered in the blood, the lungs, the spleen, the kidneys, or in the liver in cholera, but that the intestinal mucous membrane was permeated by certain bacilli which nearly resembled in size and form the bacilli found in glanders. As is well known these bacilli are straight, and are, in fact, uncommonly like the ordinary microphytes associated with decay. Dr. Koch also states in connexion with this subject that he had, previous to proceeding to Egypt, found similar bacilli in the intestinal mucous membrane of four natives of India, but that he had then looked upon them as due to merely post-mortem changes. When he came to Egypt,

Digitized by Google

however, and found these same bacilli in the intestines of perfectly fresh cases, he felt that an important link was furnished towards establishing the identity of the disease in Egypt with Indian cholera.

It is highly probable that the specimens from India which Dr. Koch had examined were those which were sent, at the request of the Imperial Health Department in Berlin, by the Sanitary Commissioner with the Government of India. These consisted of numerous dry-cover glass specimens of blood which I had collected from several cholera patients, and of portions of the viscera of four natives who had died of the disease. All these were examined by me before they were despatched, and portions of each were reserved for further study. I had heard nothing further of them, but the publication of the remarks above referred to in Dr. Koch's Report of September 17th, 1883, from Alexandria, recalled them to my mind, and I was glad to infer that my own negative results had been confirmed in Berlin. As already observed, no importance had been originally attached to the organisms which were present in the intestinal mucosa. During the last six months I have examined hundreds of stained microtome-sections of these four, and of other specimens of cholera intestines in my possession, and have found that when the mucosa is infiltrated with microphytes at all they are either micrococci, bacteria, or long-oval, and straight bacilli.

In the report of the Commission, dated Calcutta, February 2nd, 1884, Dr. Koch, however, announces for the first time that the specific bacillus of cholera is curved or comma-shaped, and not straight, so that apparently it had become necessary to abandon the microbe first fixed upon. Assuming that the four specimens from natives of India which had been examined by Dr. Koch were those which passed through my hands, the evidence they furnish seems to be in accordance with this view, as in not one of them have I been able to detect any invasion by unmistakable "commas," though at least one of the specimens may fairly be characterised as abundantly infiltrated (in the manner described by Dr. Koch) by straight (and as I prefer to call them) putrefactive bacilli. Judging from my own experience, therefore, any extensive infiltration of the intestinal mucous membrane in cholera by comma-shaped bacilli must be exceedingly rare; and this, I believe, is likewise the experience of the members of the late French Cholera Commission, MM. Straus, Roux, and Nocard, whose acquaintance I had the pleasure of making at M. Pasteur's laboratory on my return through Paris.

Whilst at Marseilles I had, as already stated, opportunities of observing numerous specimens of choleraic excreta, and found that comma-shaped bacilli were, more or less conspicuously, present in all of them, though in some instances more than one slide had to be examined before any could be satisfactorily detected. It may also be mentioned that some of the discharges in which these organisms were present manifested an acid reaction when tested with litmus paper. As Dr. Koch himself remarks, the proportion which the comma-shaped bacilli bear to other organisms in the dejecta varies greatly. In some instances only one or two specimens are to be found in the field of the microscope, while in others they are very numerous, and Drs. Nicati and Rietsch (who are at present engaged in the study of the disease at Marseilles) were so kind as to show me a specimen of choleraic material they had obtained from the small intestine, in which the "commas" existed almost to the exclusion of all other organisms. This is a condition, however, which, I understand, is exceedingly rare. On the other hand, I have seen samples of choleraic dejecta in which totally different organisms prevailed to a like exclusion of others; and in one instance at Marseilles spirilla of various sizes and forms were the most conspicuous of the micro-organisms present. So far, therefore, the selection of the comma-shaped bacilli as the *materies morbi* of cholera appears to be entirely arbitrary.

Dr. Koch and his colleagues have adduced no evidence to show that they are more pernicious than any other microbe; indeed, as a matter of fact, the sole argument of any weight which has been brought forward in favour of the comma-shaped bacillus being the cause of cholera is the circumstance that it is more or less prevalent in every case of the disease, and that the German Commission had not succeeded in finding it in any other. With regard to the suggestion that the cholera process may in some way favour the growth of these bacilli, and that these are not necessarily the cause of the disease, Dr. Koch remarks, in the report from Calcutta above cited, that such a view is untenable, inasmuch as it would have to be assumed "that the alimentary canal of a person stricken with cholera must have already contained these particular bacteria; and, seeing that they have invariably been found in a comparatively large number of cases of the disease both in Egypt and India—two wholly separate countries,—it would be necessary to assume, further, that every individual must harbour them in his system. This, however, cannot be the case, because, as already stated, the comma-like bacilli are never found except in cases of cholera."

† S-shaped comma bacilli.

Had Dr. Koch and his colleagues submitted the secretions of the mouth and fauces—the very commencement of the alimentary canal—to a careful microscopic examination of the same kind as that to which they have submitted the alvine discharges, I feel persuaded that such a sentence as the foregoing would not have been written, seeing that comma-like bacilli identical in size, form, and in their reaction with aniline dyes, with those found in choleraic dejecta, are ordinarily present in the mouth of perfectly healthy persons.

[Since this memorandum was submitted I have observed that Dr. Koch states, in his recent address on the subject, that after his return to Berlin he had examined, amongst other things, the secretions of the mouth for comma-shaped bacilli, but had found none; and, further, that he had consulted persons of much experience in bacterial researches as to whether they had ever seen such organisms, and was told that they had not. It may be of assistance to future observers if I give the dimensions of half-a-dozen comma-shaped bacilli, as found in each of the following: (*a*) In the alvine discharges of three cholera-affected persons; (*b*) in the small intestine of a person who had died of the disease, and in whom they existed almost to the exclusion of other organisms; (*c*) in a cultivation of them in agar-agar jelly; and (*d*) in the secretions of the mouth of three healthy persons, ranging from four to fifty years of age. The measurements were made (with the valuable assistance of Mr. Arthur E. Brown, B.Sc. Lond., under a magnifying power of 1000 diameters, a Powell and Lealand's $\frac{1}{25}$th of an inch oil-immersion lens, with a wide angle condenser, being used.] See Table, *supra*.

There is no difficulty in putting this statement to the test; and to any one acquainted with the methods ordinarily

Digitized by Google

adopted for staining and mounting fungal organisms of this character, no special directions need be given. The procedure followed by me to demonstrate these "commas" in the saliva is precisely that adopted for finding them in the dejections. A little saliva should be placed on a cover-glass (preferably in the morning before the teeth are brushed), and allowed to dry thoroughly, either spontaneously or aided by a gentle heat. The dry film thus obtained should be floated for a minute or two with one or other of the ordinary solutions of aniline dyes adopted for such purposes, such, for example, as fuchsine, gentian-violet, or methylene blue. The cover should then be gently rinsed with distilled water, and the film re-dried thoroughly. The preparation may now be mounted in dammar varnish or Canada balsam dissolved in benzol, and should be examined under a $\frac{1}{12}$th or $\frac{1}{18}$th of an inch oil-immersion lens.

As in choleraic discharges so in the saliva, the number of comma-shaped bacilli will be found to vary greatly in different persons, and at different times in the same person. Sometimes only one or two "commas" will be seen in the field, at others a dozen may be counted, and, occasionally, little colony-groups of them may be found scattered here and there throughout the slide.

It may be remarked in passing, and as bearing upon what has been already said regarding the general absence of comma-shaped bacteria from the intestinal mucosa itself, that they do not appear to manifest any special tendency for attacking the decaying epithelial scales of the mouth, but that, on the contrary, they are for the most part found free in the fluid, the epithelium being studded with other bacterial forms.

Persons who have not been in the habit of examining dried saliva-films will probably be surprised at the number and variety of the organisms which are, more or less, constantly to be found in the mouth, and especially at the number of spirilla with which the fluid is generally crowded.

The alvine discharges in cholera sometimes swarm with precisely similar spiral organisms, and, indeed, as has long been known, the fluid exuded into the intestines in this disease is peculiarly suitable for the growth of these and allied microbes. But, so far as my own experience—dating from 1869—of the microscopic examination of such a fluid goes, all the microphytes ordinarily found in it are likewise to be found, to a greater or less extent, in the secretions of the mouth and fauces of unaffected persons. And with reference to the comma-like bacilli found in cholera, to which such virulent properties have been ascribed, I shall continue to regard them as identical in their nature with those ordinarily present in the saliva until it has been clearly demonstrated that they are physiologically different.

INSANITY IN NEW SOUTH WALES.

IN his report for the year 1883, Dr. Norton Manning, the Inspector-General of the Insane for New South Wales, gives the number of insane persons in the colony on Dec. 31st as 2403—viz., 1474 male and 929 female. This is an actual increase, as compared with the same date in 1882, of 96—44 males and 52 females; but the rate of increase among the insane in proportion to the general population is stated to be somewhat less than usual. The returns given show that, "though during the ten years from 1864 to 1873 there was a considerable increase in the proportion of insane persons under care, and in the number admitted, there has been little or no increase during the last ten years either in the accumulated cases or in the admissions or 'occurring cases' in proportion to the general population, and that the 'burden,' as it is fitly called, of insanity, is at a standstill." A comparative statement is made as regards the proportion of insane to population in the colony and in England. From this it appears that in England there has been a steady increase in the proportion from the year 1864, when it was 1 insane person in 457 of the population, down to the year 1882, when it was 1 in 348. It also appears that a general, though less steady, increase has taken place in the colony from 1 in 399 in the year 1864, to 1 in 354 in the year 1882. At the end of the year 1881 the proportion stood at 1 in 352 both in the colony and in the mother country, a point which cannot fail to give interest to the comparative statistics in years to come. The insane in New South Wales are distributed in varying proportions through five hospitals for the insane and one licensed house. The hospitals are overcrowded, and they contain as many as 232 in excess of the 2025 for whom accommodation is provided. The inspector-general is taking measures to remedy this unwholesome state of affairs, which is in a great measure due to the accumulation of aged and quiet patients, who in Great Britain are ordinarily provided for in workhouses. The percentage of recoveries on admissions and readmissions for the year was 40·7, and the percentage of deaths on the average number resident was 6·6—males, 7·7; females, 5·0.

There were 476 admissions and readmissions during the year; and in only ten, or a little over 2 per cent., of these was hereditary influence ascertained. This is a small proportion, and if an explanation were looked for, it might be found in the absence of relatives who could give information regarding individual waifs and strays who wander "far from their home," and are unable to give any reliable account of themselves or of their belongings. And, indeed, a reference to Table 9 seems to bear out this idea, for, from figures there given, only 23 per cent. of the entire insane population were natives of New South Wales, leaving a burdensome margin for the immigrant population, largely drafted from the restless and wandering element of humanity, and represented by individuals who too often, apparently, arrive by sea, if they are not actually shipped, in a state of positive insanity. The report states that after a lengthy correspondence the French Government have agreed to retain and provide for the insane persons of British nationality who become insane in New Caledonia, in the same way as has been done for years past by the Government of New South Wales in regard to persons of French nationality who are thrown upon their hands. During the year, thirty patients had been discharged as relieved to the care of friends; but it has not yet been found practicable to take any steps towards "boarding out" patients, or placing them with strangers paid for their maintenance. The circumstances of colonial life, especially when of the "bush" type, the absence of suitable village homes, and the relations of labour and wages, combine to form a group of obstacles to the adoption of the system, and these obstacles are not likely to be readily overcome. The number of escapes was thirty-one, and all, with one exception, were recaptured within fourteen days, the great majority having had a run of less than twenty-four hours.

The accidents and injuries do not appear to have been numerous and none of them were fatal. There was only one suicide; in the case of a male patient who cut his throat with a piece of glass bottle. With regard to restraint, we are informed that it is never used without the direct order of a medical officer, except in institutions without a resident medical officer, where the superintendent may place a patient in restraint with the subsequent sanction of the visiting medical officer. The propriety of permitting any layman to place a sick person, or an individual under medical treatment, in a camisole or strait-jacket cannot be upheld, and it would be well that such an anomalous exception were done away with. Restraint is not, however, very largely used, for the returns sent to the inspector-general show that the amount never exceeds one patient in restraint out of every 400, and is frequently much less, and that in half of the cases it is employed for surgical reasons. The inspector-general sums up his experience of restraint in the following terms: "Under proper regulations it has a useful place in the treatment of insanity, and I hold that the position taken by the physicians of American hospitals is in this respect more philosophical and more humane than the extreme views held by some alienists in Great Britain." No general statement is given of the amount of seclusion that was had recourse to, although it may be gleaned that in some of the asylums, at least, it is not extensively made use of. The average weekly cost per patient in hospitals for the insane in New South Wales is 12*s.* 5¾*d.*, being 2*s.* greater than that in English borough asylums, which is 10*s.* 5½*d.* The main difference in cost is due to the amount for salaries and wages of attendants, nurses, and servants being larger in this colony than in England. It could have been a useful piece of information if the report, dealing as it does with so many attractive points of detail and management, had given the relative proportion of attendants, nurses, &c., to the insane population, for this is an important factor in the safe and successful administration of asylums.

Altogether, the report is highly interesting and instructive, and shows excellent results. It appears, on the face of it, to be an honest record of good and useful administrative and inspectorial work among the insane of New South Wales.

INTERNATIONAL MEDICAL CONGRESS AT COPENHAGEN.

SECTION OF MEDICINE.

Chronic Diarrhœa and Dysentery in Persons returned from Hospital to Temperate Climates.—Sir Joseph Fayrer (London) and Dr. Joseph Ewart (Brighton), after summarising the pathology, etiology, and symptoms of these dangerous affections, strongly recommended a pure milk diet to the exclusion of all medicine, excepting, occasionally, lime-water, five minim doses of laudanum and fresh bark, and a saline aperient to overcome any troublesome portal congestion that may be found to interfere with digestion and assimilation. They have found "that by absolute rest, the maintenance of the surface at an even temperature in an airy well-ventilated room, and milk alone, either pure or diluted if necessary, given at first in small quantities every half hour or every hour, suitable to the digestive powers of the patient, gradually increased as these and the diarrhœa improve, until three or four quarts for an adult are consumed in twenty-four hours, recovery is rapidly effected in a vast majority of cases." Their views are backed by a record of ten cases illustrating the advantages of this mode of treatment.

SECTION OF MILITARY MEDICINE.

Sunstroke and Thermic Fever.—Sir Joseph Fayrer, in a paper on this subject, devoted much attention to the general effects of heat in causing impaired health in hot climates. He then summarised the three forms in which the direct or indirect application of heat may be emphasised and expressed: 1, in syncope from exhaustion; 2, an analogous condition in which the respiratory centre is involved; 3, overheating of the whole body with thermic fever of great intensity. The treatment of each of these conditions was carefully elaborated, with a view to reduce temperature without undue lowering of vital power; and caution was enjoined in not lightly sanctioning a return to hot climates of those who had once suffered from insolation. This is the rule that should be observed.

Typhoid or Enteric Fever among Soldiers in the Tropics.—Dr. Joseph Ewart (Brighton) dealt with this important subject. He pointed out that until it was recognised by Scriven among Europeans, and himself among natives, thirty years ago, it had been grouped among continued and remittent fevers. The returns now show that it causes more deaths among the troops in India than cholera. Facts are given which go to show, first, that its prevalence is altogether independent of malaria, and, secondly, that it is intimately related to rise of temperature. He does not encourage the use of the term "typho-malarial" for cases complicated with malarial poisoning. "It would be as reasonable to call a case of small-pox ushered in by ague, liable to recur and modify the course and character of the exanthem, if not controlled and checked by quinine, variolo-malarial fever." The etiology is exhaustively dealt with, and it is pointed out that, as contended by Sir Joseph Fayrer and others, "it is quite possible that the fæcal-filth theory of causation may not cover the whole ground, and that the poison may perhaps thrive and propagate in other kinds of filth."

THE CHOLERA EPIDEMIC—ROME, MADRID, THE PYRENEES.

THE official bulletin in reference to the cholera issued at Rome on the 17th inst. reported from the provinces as follows:—Benevento, 1 case; Bergamo, 12 cases, 3 deaths; Caserta, 4 cases, 2 deaths; Chieti, 1 fatal case; Cremona, 5 cases, 1 death; Como, 17 cases, 12 deaths; Genoa, 24 cases, of which 11 were at Spezia, and 12 deaths, 10 being at Spezia; Reggio d'Emilia, 2 cases; and Turin, 2 cases. In the city of Naples the bulletin shows that from midnight of the 15th inst. to midnight of the 16th inst. there were 463 cases and 158 deaths. In addition, 107 of the patients previously under treatment succumbed. In the remainder of the province of Naples there have been 51 cases and 25 deaths.

The bulletin issued at Madrid states that on the 16th inst. 9 cases of cholera and 7 deaths occurred at Elche, 1 death at Novelda, and 3 cases and 3 deaths at Monforte. In the province of Lerida 3 cases have occurred at Torres de Segre. In the province of Tarragona there have been several cases, and 6 deaths during the last few days at Borjasdel campo. At Benifallet there were 30 cases on the 16th, and 8 deaths occurred during the 14th, 15th, and 16th inst. At Mora de Ebro there have been two cases, and at Ribarroja 4 cases and 2 deaths.

The accounts published in Paris on the 17th inst. announce 18 cases of cholera during the previous twenty-four hours in the Pyrenees Orientales, of which 3 occurred at Perpignan and 1 at Port Vendres.

PRIZES AND SCHOLARSHIPS IN THE METROPOLITAN MEDICAL SCHOOLS.

THE following are the principal prizes, &c., awarded for the session 1883-84 in the various London medical schools:—

ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE.—Lawrence Scholarship and Gold Medal: S. O. Habershon. Brackenbury Medical Scholarship: A. H. Garrod and G. C. Murray. Brackenbury Surgical Scholarship: W. T. H. Spicer. Senior Scholarship in Anatomy, Physiology, and Chemistry: W. G. Spencer. Open Scholarships in Science: F. M. Brown and J. G. C. Colly, equal; and H. G. Adamson and S. Blackmore, equal. Preliminary Scientific Exhibition: J. Wilkie. Jeaffreson Exhibition: S. Wilkie. Kirke's Gold Medal: S. O. Habershon. Bentley Prize: A. G. Francis. Hichens Prize: H. D. Rolleston. Harvey Prize: T. W. Green. Practical Anatomy, Junior: Treasurer's Prize, T. J. Dabell. Practical Anatomy, Senior: Foster Prize, T. W. Green.

LONDON HOSPITAL MEDICAL COLLEGE.—Entrance Science Scholarships for proficiency in the subjects required for the Preliminary Scientific M.B. Examination at the University of London: £60 Scholarship, G. G. Borrett; £40 Scholarship, C. R. Killick. Buxton Scholarships for proficiency in the subjects required for the preliminary Examinations: £30 Scholarship, H. E. Fernandes; £20 Scholarship, A. Fagan. Clinical Medicine: £20 Scholarship, H. Cropley. Clinical Surgery: £20 Scholarship, W. T. Rees. Clinical Obstetrics: £20 Scholarship, J. M. Evans and S. R. Hodge. Letheby Prize for proficiency in Chemistry: £30, Kelson and Rowden, equal; prize divided. Anatomy, Physiology, and Chemistry: £25 Scholarship, H. Smith. Anatomy and Physiology: £20 Scholarship, Ashe. Dressers' Prizes, for zeal, efficiency, and knowledge of Minor Surgery: £15 prizes, N. R. Howse and W. T. Mould; £10 prize, E. J. A. Haynes; £5 prize, G. C. W. Wright.

GUY'S HOSPITAL MEDICAL SCHOOL.—The Treasurer's Gold Medal in Medicine: Albert Martin, M.B. The Treasurer's Gold Medal in Surgery: George E. C. Anderson. The Mackenzie Bacon Prize for Ophthalmoscopy: James Henry Targett, M.B. The Mackenzie Bacon Prize for Nervous Diseases: William Leonard Braddon. The Burdett Prize for Hygiene: Hubert H. Du Boulay. Fourth-year Students: George E. C. Anderson, first prize, £25; William Leonard Braddon, second prize, £10. Third-year Students: Frederick Lever, first prize, £25; Sidney Wacher, second prize, £10. Second-year Students (Joseph Hoare prizes): Henry W. Drew, first prize, £25; Frederick François Burghead, second prize, £10. First-year Students: Ernest Henry Starling, first prize, £50; Guy Bellingham Smith, second prize, £25.

KING'S COLLEGE.—Winter Session.—The Jelf Medal: John Power Gray. Warneford Endowment: Albert Carless and John Power Gray, prizes. Leathes' Endowment: Albert Carless and Richard John Stephens, prizes. Divinity:—Third year: Benjamin John Wright, prize. Second year: Horatio Nelson Baron and Philip Henry Hensley, prizes. First year: Harold Burgess Osburn, Jeremiah Penny and Henry Smith, prizes. Anatomy: Charles Drinkwater, prize. Physiology: Henry Alexander Pope, prize. Chemistry: George Hartley O'Reilly, prize. Medicine: John Power Gray, prize. Clinical Medicine: Francis James Warwick, prize. Surgery: Obadiah Johnson, prize. Clinical Surgery (Professor Wood): John Frail Harries, prize. Clinical Surgery (Professor Lister): Robert Chambers Priestley, prize. Comparative Anatomy and Zoology: John Major Bull, prize.—Summer Session: The Tanner Prize: Frederick Arthur O'Meara. Obstetric Medicine: Albert Carless, prize. Forensic Medicine: Philip Percy Manning,

Digitized by Google

prize. Materia Medica: George Hartley O'Reilly and Henry Smith, equal, prizes. Practical Chemistry: Allan James M'Nab, prize. Botany: Herbert Stanley Ballance, prize. The Carter Gold Medal and Prize for Botany: Jeremiah Penny. Pathological Anatomy: Albert Carless, prize. Practical Physiology: George Arthur Bray and Herbert Arthur Smith, equal, prizes. Practical Biology: Peyton Todd Beale, prize. The Todd Prize for Clinical Medicine: Robert Loxham Hildyard.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—The Treasurer's Prize, value £10 10s.: P. Pinhorn. The Thompson Medal: Robert Trevor. The Pollock Prize in Physiology: Arthur Heygate Vernon. Sir Charles Clarke's Prize for good conduct: Richard Emmett.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—Entrance Exhibitions: 1, C. J. Lownds (Houldsworth), value £40 per annum; 2, F. R. P. Taylor and C. S. Vines, equal, value £40. Treasurer's Prize for First Winter subjects, value 20 guineas: W. Powell. President's Prize for Second Year subjects, value 20 guineas: C. Burt. Chadwick Prize, value 20 guineas: W. Weaver. Bird Prize, value £15: J. Swain. Clinical Medicine, value £5: W. Weaver. Clinical Surgery, value £5: W. Weaver, J. Swain. Class Prizes and Certificates: Anatomy, Senior Class: C. Burt; Junior Class: A. H. W. Hunt (prize). Physiology, Senior Class: C. Burt; Junior Class: W. Powell. Histology, Senior Class, C. Burt. Chemistry, Senior Class: W. Powell (prize). Medicine, Senior Class: W. Weaver (prize). Surgery, Senior Class: W. A. Wills (prize).

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—Scholarships in Natural Science of £50: J. T. Bays, N. C. Ridley, W. B. Bottomley, and H. A. Kidd. Exhibition of 25 guineas: M. M. Bird. Scholarships in Pathology: G. A. Allen and A. Hastings Stewart. Scholarship in Anatomy: G. W. H. French. Prosectors: G. A. Barton and J. J. Clarke. Rolleston Prize, Biology: E. Evans. Prizes in Physiology: Callender and E. Evans. Summer Session, 1883: Materia Medica, J. J. Clarke, prize. Botany: J. J. Clarke and W. Williams (equal), prize. Practical Chemistry: G. A. Barton, prize. Midwifery: J. Q. Bown, prize. Medical Jurisprudence: G. N. Caley and G. Spear (equal), prize. Winter Session, 1883-84.—First Year—Anatomy and Histology: J. T. Bays, first prize; H. S. Collier, second prize. Chemistry: J. C. Barr, prize. Second Year—Anatomy and Physiology: J. J. Clarke, prize. Third Year—Medicine: J. Q. Bown and G. N. Caley (equal), prize. Surgery: J. Q. Bown, first prize; H. Tanner, second prize. Practical Surgery: H. Tanner, prize. Pathology: E. Evans, prize. Third and Fourth Years—Clinical Medicine: J. Q. Bown and — Fernandez, prizes. Clinical Surgery: G. N. Caley, prize. Prizes in Ophthalmology of £10 10s. each: A. H. Willoughby and G. A. Allen.

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL.—Broderip Scholarships, for the best examination at the bedside and in the post-mortem room: First, C. L. Hudson; second, A. F. Stace. Governor's prize, T. H. Williams. Exhibition in Anatomy, First year: W. G. Nash. Lyell medal: W. A. Furmston. Medicine: J. R. Roberts. Surgery: J. R. Roberts, T. H. Williams. Pathological Anatomy: J. R. Roberts. Practical Surgery: W. A. Furmston. Anatomy: H. Bartlett. Physiology: H. Bartlett. Chemistry: T. H. Clarke. Midwifery: W. A. Furmston. Forensic Medicine: W. A. Furmston. Materia Medica: W. B. Cockill. Practical Chemistry: W. H. Vickery. Botany: W. G. Nash. Practical Physiology: E. E. Lewis. Comparative Anatomy: H. Bartlett. Psychological Medicine: W. A. Furmston, T. H. Williams. Medical Society's Prizes: E. H. Freeland (paper), Bernard Lawson (pathology), Edgar Nicholson (histology), C. L. Hudson (debate). Entrance Scholarships—First: W. B. Cockill; second, W. G. Nash. Science Scholarship: L. P. Gibson.

CHARING-CROSS HOSPITAL SCHOOL OF MEDICINE.—Llewellyn Scholarship: Certificate and £25, L. J. Pisani. Golding Scholarship: Certificate and £15, J. S. W. Chitty. Governor's Clinical Gold Medal: F. O. Stedman. The Pereira Prize: Certificate and £3 prize, E. T. Gregory. Anatomy: Senior silver medal, W. J. Colborne; Junior bronze medal, V. Sapp. Physiology (silver medal): J. G. H. Carter. Practical Physiology (silver medal): E. Cooper. Chemistry (silver medal): L. E. Sexton. Practical Chemistry (silver medal): E. H. Lingwood. Medicine: Senior silver medal, G. H. Charlesworth; Junior silver medal, W. H. Compton. Surgery: Senior silver medal, F. O. Stedman; Junior silver medal, W. J. Colborne. Botany (silver medal): J. S. W. Chitty. Materia Medica (silver medal): W. H. Compton. Midwifery (silver medal): L. J. Pisani. Forensic Medicine (silver medal): A. E. Hardy. Pathology (silver medal): G. H. Charlesworth.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

St. Asaph (Rural).—Dr. Lloyd Roberts reports a death-rate of 16·8 per 1000 for this district, and mortality amongst children under one year of age as low as 91·6 per 1000 births. Only a few isolated cases of infectious disease occurred, and the greatest want of many places in the district seems to be a proper water-supply. Some villages have, however, been so supplied, and other works tending to improve the conditions under which the people are living have been carried out.

Burgh of Dundee.—The death-rate of Dundee was high in 1883—namely, 23·9 per 1000. Dr. Anderson explains that of the large towns of Scotland Dundee stands fifth on the list, four having a lower and three a higher death-rate. This compares unfavourably with the large towns of England, for of the latter, twenty-two have a lower mortality than Dundee. The system of notification of infectious diseases is said to work most satisfactorily in every way. Not only is there no friction, but from a medical point of view it has answered admirably, detecting the existence of infectious disease. It has also incidentally led to considerable improvements in the sanitary state of the drains, by revealing at an early date the conditions under which disease was being spread by them. Dundee possesses a hospital for infectious diseases, and the mortality amongst patients removed to it, as compared with that in those treated at home, shows a difference of nearly 6 per cent. in favour of hospital treatment. This is readily understood when we learn of the 108 deaths occurring in houses; forty-three took place in tenements containing six or nine inmates—that is to say, 40 per cent. of these infectious deaths occurred amongst those whose surroundings were most unfavourable to recovery. In Dundee it is illegal for any pupil to attend school if coming from an infected household, and it is also illegal for teachers to receive them, but the law as to this is hardly observed with sufficient stringency. Intimations as to infectious disease are, however, at once transmitted to school teachers by the sanitary department, and certificates as to freedom of infection &c. are also granted. Where the law is not observed, Dr. Anderson strongly urges that legal proceedings should be taken against offenders. Appended to the report is an important statement by the sanitary inspector, giving advice as to certain details of plumbing and other matters. But we hardly like what he says about connecting overflow pipes with soil pipes, for whilst on the one hand he explains that this should under no circumstances be done, he proceeds to say that when it is done a syphon trap and a wetting pipe, to keep the syphon full, are needed. Even if this should never fail, the system is absolutely faulty, and should never be tolerated where it can be done away with. He also advocates the trapping of rain-water pipes at the bottom, together with the addition of a ventilating pipe, so as to prevent foul air getting into attic windows. But in dry weather, unfortunately, the trap becomes unsealed. Rain-water pipes, if connected with a sewer, should be cut off at the bottom, and made to flow over a trapped gully out of doors, in the same way as waste-pipes.

Tendring (Rural).—Dr. J. W. Cook, in his annual report on this sanitary district, again draws attention to the need for providing Brightlingsea with proper drainage and sewerage. At Clacton-on-Sea a system of sewers is all but completed—indeed, it was hoped that before this season ended the system would be at work. Water supply still seems to be a difficulty in some localties, notably at Parkeston and in the village of Mistley; and at Great Oakley Hall an outbreak of typhoid fever was due to well-pollution at a dairy. The milk was sold in Harwich, and typoid fever was found to be prevailing in that town amongst the consumers of milk from the dairy in question. The sale of milk was at once stopped, the well was closed, and the disease ceased. Typhus is

Digitized by Google

reported as having occurred at Frating, and the disease is set down as due to the bad state of the drains and to a polluted well. There was probably some error of diagnosis here for such localties do not suffer from typhus except as the result of importation, and typhus cannot be regarded as having its cause in such sanitary circumstances as are specified. The death-rate of the district stands at 16·3 per 1000.

Wednesbury (*Urban*).—Mr. Garman reports the death-rate of this town as 19·9 per 1000. Scarlet fever became epidemic towards the end of 1883, and was very fatal. Diphtheria also prevailed concurrently with it. Thirteen scarlet fever and four diphtheria deaths were registered. The deaths from typhoid fever were 14 in number, and having regard to the good water-supply in the place, this number must be regarded as unnecessarily large in a population of 24,500. The midden system is stated to be under constant supervision, but in many similar localities this system, as carried out, is responsible for much typhoid and diarrhœa. In 1882 the typhoid fever deaths numbered eighteen. The report deals mainly with the prevalence of disease and with statistics, and it only incidentally refers to the sanitary circumstances of the district and the future improvements needed in it.

Barrow-in-Furness (*Urban*).—This urban district continues to grow steadily. In 1880 the population was estimated at 40,000; now the estimate is 52,000, and on this estimate the death-rate is a satisfactory one, reaching only 17·1 per 1,000. There has during the past few years been a sensible decrease in the number of infantile deaths, and the change is regarded by Mr. Settle as due to improvement both in the sanitary circumstances and also in the moral and social habits of the place. Day nurseries are, however, still needed. Enteric fever was somewhat widely prevalent in 1883, there having been 216 cases and 36 deaths, the causes being the escape of sewer air into houses and general dirtiness of houses amongst those affected. The sanitary hospital was useful during its prevalence, thirty-one cases being admitted. A list of sanitary works carried out shows that continuous improvement in regard to details is constantly in progress.

Hull (*Urban*).—With an estimated population of 176,296, the death-rate of this important borough was, during 1883, 22·5 per 1000, and the birth-rate 36·0. The infantile mortality, as measured by the proportion of deaths under one year to births, was high—namely, 183 per 1000. The zymotic death-rate was much lower than the average for the past ten years, reaching as it did 2·91 per 1000, diphtheria and whooping-cough alone being in excess of the rates for the previous year, when scarlet fever and diarrhœa were prevalent. Referring to the somewhat prevalent opinion that there is a certain relationship between scarlatina and diphtheria both in origin and pathology, Dr. Mason expresses the view that no such relationship exists, the diseases being distinct as regards origin, and differing materially in their pathological bearing. The genuine diphtheria which prevailed had, however, a definite relation to a group of seemingly simple sore-throats. The question of providing adequately for the isolation of infectious diseases in the port of Hull has engaged much attention, but as yet no determination has been arrived at. The current sanitary work of the district makes steady progress. Hull was early in the van of towns which promoted frequent collection of filth and refuse, and the work has never been more efficiently performed than it is now. A house-to-house inspection—one of the most important of sanitary duties—is in progress, and must materially tend to the removal of local conditions of ill-health; so also, such defects in connexion with the sewage and other matters as are detected have either been dealt with or are receiving attention.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

During the week ending the 13th inst., 5768 births and [illegible] deaths were registered in twenty-eight of the largest English towns. The annual rate of mortality in these towns, which in the three preceding weeks had been 20·6, 20·3, [illegible] and 20·9, rose last week to 21·4. During [illegible] corresponding weeks of the current quarter the death-rate [illegible] 1883. The [illegible] Wolverhampton, 18·6 in Derby, and 20·1 in Birkenhead. The rates ranged upwards in the other towns to 31·0 in Leicester, 32·0 in Wolverhampton, 32·4 in Cardiff, and 35·4 in Blackburn. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 1314, 1260, and 1147 in the three previous weeks, further declined last week to 802; these included 531 from diarrhœa, 71 from whooping-cough, 65 from scarlet fever, 46 from measles, 45 from "fever" (principally enteric), 31 from diphtheria, and 13 from small-pox. These diseases caused the lowest death-rates in Derby, Brighton, and Plymouth, and the highest in Hull, Blackburn, and Preston. Measles caused the highest proportional fatality in Preston and Halifax; scarlet fever in Leeds, Sheffield, and Cardiff; whooping-cough in Leeds and Birmingham; "fever" in Bolton and Norwich; and diarrhœa in Preston, Leicester, and Blackburn. The 31 deaths from diphtheria in the twenty-eight towns included 22 in London, 3 in Salford, 2 in Liverpool, and 2 in Leeds. Small-pox caused 9 deaths in London, 2 in Liverpool, 1 in Sheffield, and 1 in Hull. The number of small-pox patients in the metropolitan asylum hospitals [illegible] in and around London, which in the nine preceding weeks had declined from 1368 to 530, further fell to 477 on Saturday last; the new cases admitted were 66, against 53, 63, and 77 in the three previous weeks. The Highgate Small-pox Hospital contained 31 patients on Saturday last, 4 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which in the two preceding weeks had been 181 and 167, were last week to 170, and 12 below the average. The causes of 69, or only 1·9 per cent., of the 3588 deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Norwich, Leicester, Nottingham, and in five smaller towns. The largest proportions of uncertified deaths were recorded in Halifax, Newcastle-upon-Tyne, and Birkenhead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which in the three preceding weeks had been 21·8, 20·[illegible] 20·5, rose to 21·5 during the week ending the 13th inst.; it almost corresponded with the mean rate during the same period in the twenty-eight large English towns. In the Scotch towns the rates last week ranged from 15·0 [illegible] in Aberdeen and Edinburgh, to 24·7 in Glasgow, [illegible] Leith. The 519 deaths in the Scotch towns included [illegible] which were referred to diarrhœal diseases, 21 to whooping-cough, 17 to scarlet fever, 15 to diphtheria, 10 to [illegible] and not one either to small-pox or measles; in all, 113 [illegible] resulted from these principal zymotic diseases, against [illegible] and 127 in the two preceding weeks. These [illegible] were equal to an annual rate of 4·9 per 1000, which [illegible] exceeded the average rate from the same diseases [illegible] in the twenty-eight English towns. The deaths [illegible] to diarrhœa, which had been 74, 68, and 55 in the [illegible] vious weeks, were again 55 last week, and exceeded [illegible] the number in the corresponding week of last year [illegible] occurred in Glasgow and 10 in Dundee. The 21 fatal [illegible] of whooping-cough showed a slight further decline [illegible] recent weekly numbers, and included 10 in Glasgow [illegible] Dundee, and 3 in Aberdeen. Of the 17 deaths from [illegible] fever 13 were returned in Glasgow and 2 in Edinburgh. The 15 fatal cases of diphtheria showed a slight increase upon recent weekly numbers, and included 8 in Glasgow, 2 in Dundee, and 2 in Aberdeen. The 10 [illegible] from "fever" also showed an increase; 5 were [illegible] Glasgow, 3 in Paisley, and 2 in Edinburgh. The [illegible] referred to acute diseases of the respiratory organs [illegible] eight Scotch towns showed a slight further increase [illegible] the numbers in recent weeks, but were below those recorded in the corresponding week of last year. The [illegible] or more than 15 per cent., of the deaths in the [illegible] towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had [illegible] the three preceding weeks from 30·3 to 29·3 per [illegible] 29·4 in the week ending the 13th inst. During the eleven weeks of the current quarter the death-rate in the city averaged 24·8 per 1000, the rate during the same period being 21·7 in London and 16·5 in Edinburgh. The deaths in Dublin last week exceeded by 1 the number

Digitized by Google

in the preceding week, and included 42 which were referred to the principal zymotic diseases, against 65 and 42 in the two preceding weeks; of these, 24 resulted from diarrhœal diseases, 11 from scarlet fever, 4 from "fever," 2 from diphtheria, 1 from whooping-cough, and not one either from small-pox or measles. These 42 deaths were equal to an annual rate of 6·2 per 1000, the rate from the same diseases not exceeding 3·1 in London and 2·5 in Edinburgh. The fatal cases of diarrhœa, which had been 48 and 29 in the two previous weeks, further declined last week to 24. The deaths referred to scarlet fever, which had declined from 13 to 7 in the three preceding weeks, rose again to 11 last week. The 4 fatal cases of fever exceeded the number in any recent week. The fatality of whooping-cough showed a marked decline from that recorded in the three previous weeks. Three inquest cases and 1 death from violence were registered in the city during last week, and 47 deaths occurred in public institutions. The deaths of infants showed a considerable decline from recent weekly numbers, while those of elderly persons were more numerous. The causes of 38, or more than 19 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

THE ALLEGED CAUSE OF CHOLERA.

To the Editor of THE LANCET.

SIR,—There is no subject on which the same amount of labour and observation has been bestowed with so little real or apparent advance as that which forms the heading of this communication. It has fallen to my lot to have seen much of cholera, and it was my good fortune to have known intimately the late Dr. James Bryden, than whom a more truthful or philosophical-minded man did not exist. Strong lights are unnecessary, true ones being at command, says Selden; and it seems strange, where every fresh theory or hypothesis appears destined to add but another to the many scientific pitfalls for the footsteps of the unwary, that the works of a man who sedulously endeavoured to compile such a truthful record of facts that it might have been written, so to say, by cholera itself, and merely chronicled by him, should have received so little attention at the present time.

It is but easy as it is common to drop down with the tide of the latest popular view—the current doctrine of the day; but it unfortunately often happens that the facts are all going the opposite way.

As I propose briefly commenting on the latest view of a most distinguished and competent histologist, I desire to guard against being thought to possess any sympathy with the Philistinism of the day, which roughly ridicules what it cannot understand or appreciate. I quite appreciate and sympathise with the labours of such men as Koch and his *confrères*, but it must be remembered that it is truth, not victory, that has to be sought. It is humiliating to have to confess that we are still ignorant of the cause of cholera, for the latest alleged discovery of it is not, I fear, destined to prove "the light."

Koch, it, he says, found a bacillus of comma-like form in all cases of cholera, and in that disease alone. These bacilli are met with in the small intestines, which are the seat of the disease; they swarm in the inodorous watery alkaline fluid which characterises a certain stage of that disease, being substitutionary apparently of those micro-organisms ordinarily found. These bacilli are easily destroyed by desiccation, by acids, even by so weak a one as that of the gastric juice, and so on. The outcome of his observations is that these micro-organisms are the cause, and not the effect or concomitant, of cholera. All attempts to impart the disease to the lower animals by inoculation have, however, failed.

Several steps in the argument are assumed. For instance, that the fact that the small intestine is the seat of the disease? In cholera the body is, as it were, dominated by a morbid influence, under which exosmosis is everything, endosmosis *nil*. There is in most cases an enormous transudation of alkaline serous fluid into the intestines during one stage (rice-water) of the disease; but that does not justify us in stating as a logical inference that the small intestine is the seat of the disease, any more than we should be justified in saying that the doors of a theatre in case of a panic from an alarm of fire were the seat of the disaster in the theatre.

Next (*a*) it must be shown without any shadow of doubt that these comma-like bacilli are absent in every other disease, and in healthy individuals under ordinary circumstances; and for this purpose the number of observations recorded by Koch to establish it are, to my mind, insufficient. (*b*) Further, it must be shown that the bacillus is a specific object, and not a mere differentiation from some common microbe, owing to the nature of the menstruum in which these latter float, and on which they are presumably nourished.

Although it may be true that, in regard to shape, bacteria are very constant and one kind is not changed into another, experiments are required to prove what would be the effect of subjecting the micro-parasites ordinarily present in the body to contact with a mucous membrane and an alkaline fluid like that found in cholera intestines. Why does a pancreatic digestive mixture soon swarm with bacteria when the natural juice or an infusion of the gland is used. (Foster's "Physiology," pp. 253–298). It is difficult to understand how the intestines can be the sole breeding-ground or infecting depôt, so to say, of these bacilli, which are to produce all the morbid phenomena witnessed in cholera. Koch has not detected these comma bacilli in the blood, liver, spleen, or kidneys. Again, take the effects of desiccation, and how are we to explain the survival of this bacillus in the plains of India? If the gastric juice of a healthy stomach has sufficient acidity to destroy the bacillus, it should follow that the stomach is the safest place to put it. Koch has apparently to evoke the aid of some trifling indigestion or gastric derangement on the part of those attacked; but is not this an assumption, and, at least as far as some cases are concerned, opposed to experience? Does he hold, as he seems to do, that the cholera cause can only reach the system through the gastro-intestinal tract? On what evidence?

How does cholera, as a matter of fact, comport itself in India? This cholera bacillus must be capable of covering the two extremes of (*a*) sporadic cases, where one man is attacked and dies in a place, no other cases occurring, and (*b*) an epidemic extending over half the globe. A return of the cholera cases in Bengal for this year, or for any year, would show that isolated cases at numerous stations, widely separated from one another, are common phenomena; and further, these so-called sporadic cases at certain seasons are often the precursors of epidemics later on. How are we to account, on the one hand, for the apparently spontaneous origin of this cholera bacillus at one time and place, and for its limited sphere of action; and, on the other, for its enormous and rapid development when the disease is spreading as an epidemic?

The regularity of the course of epidemic cholera in Bengal—its relation to time and space—could be easily illustrated. Why is it, in the first year of its advance to the north-west, so often limited by the line of 80° E. long.? It has been lately discovered that at this longitude the two monsoon currents from the Bay of Bengal and Arabian Gulf meet, and must there give rise to an ascential current. It would be easy to illustrate this and other circumstances connected with the past history of epidemic cholera in Bengal by some striking tables embodying the results of repeated observation; and they cannot surely be mere coincidences.

Again, how are we to explain the almost simultaneous outbreak of cholera at so many and distant stations? How are we to explain the contrast exhibited by Peshawar as compared with other places in regard to epidemic cholera? In Peshawar a cholera epidemic will continue till December; in other places, say the Punjab, it is over as an epidemic by the end of September. A great deal has been said from time to time about the influence of water as the vehicle of a *specific*, as contra-distinguished from a *common*, cause of impurity. In the celebrated Broad-street pump case the outbreak was almost identical in its course and duration with a typical outbreak in a regiment on the march in India; and the fact of the fatal cases ceasing at once after closure of the well is against that having been the cause.

The course of an epidemic of cholera in Bengal, instead

Digitized by Google

of being with is against the course of the natural drainage of the country. Of course it is no new thing that cholera hugs the banks of a stream; but it has never happened that an epidemic of cholera commenced in the Himalayas or Upper Provinces and spread gradually down the Ganges, Jumna, or Indus; its advance has been exactly opposite.

Professor Koch, misled no doubt by incorrect information, has attributed the improvement in the health of the garrison at Fort William, Calcutta, to the introduction of a pure water-supply; but the fact is that an Order in Council exists refusing to sanction the necessary expenditure for its introduction, in consequence of the remarkably good health which the Fort William garrison had then been enjoying for several years past. The town water was subsequently introduced; but there was no such causal connexion between the two things as has been alleged. There are, moreover, some facts within my knowledge connected with the prevalence of cholera on board some of the Assam steamers, and the town and district of Dacca, which would indicate how cautious we should be before considering that cholera infection through a specifically contaminated water is a demonstrated fact.

This communication has already extended to a wearisome length, therefore I will finish what I have to say next week if you will kindly grant me the necessary space.

I am, Sir, yours obediently,

J. A. MARSTON,

September, 1884. Deputy-Surgeon General, A.M.D.

"THE METAPHYSICS OF COMTE."

To the Editor of THE LANCET.

SIR,—The tone of Mr. FitzPatrick's letter makes me fear that I did wrong in using the not very elegant term "rubbishy" to qualify metaphysics. But the context would show that the worthlessness of rubbish was ascribed by me to metaphysics in general, and not only to the mystical latest phases of Comte, which are at least as like metaphysics as one fog is like another.

I certainly did not mean to speak slightingly of Comtists, and am very sorry if I seemed to do so. No mere passer-by would cast a reflection ever so remote and momentary upon the distinguished group of men known as Comtists, or Positivists. Even a wayfaring man must be moved by the aspect of a somewhat forlorn group worshipping Humanity in the cold shade of public neglect. Nay, it is even quite touching to witness their almost simple disregard of that reciprocity which more numerous and ordinary worshippers commonly have an eye to.

The Comtists made science into what they call philosophy, and philosophy into what they call religion, and having done so they worship. They worship humanity, the source of their undivine religion and science. Very few people join in the worship; and it is curious to me that the Comtists do not see why this is. They do not appear in the least to appreciate the greatest and first of truths which is at the foundation of all religion—the truth, namely, that there must be a reciprocity between worshipper and worshipped. The reciprocity is, indeed, necessarily a close one. Even Pagans have seen this greatest of truths. Cicero clearly perceived it. He remarks that the deity of elephants would have a proboscis. But the correspondence of worshipper and worshipped may be ground too sacred to admit of playful treatment. Nevertheless, I may remark how the intensely personal Jew worshipped a correspondingly personal God. Intense individuality required uncompromising monotheism. The Jew has never been able to accept Christ's simple summary of the Commandments. The intensely personified God who reciprocated to the intense ego of the Jew was even supposed by the Jew to grow jealous about him. But Humanity will never grow jealous about the Comtists, however their clever high priest, Mr. Frederick Harrison, may flirt with the Unknowable quite openly before the very eyes of Humanity in the *Nineteenth Century* and *The Times*. The weakness of the Comtists' philosophy-religion, which is neither religion nor philosophy, but which at any rate worships Humanity, is that there will never be any reciprocity of worshipper and worshipped. I must leave it to Mr. Harrison and to Mr. Spencer to settle for Mr. FitzPatrick whether Comtism includes the whole Spencerian system, metaphysics and all. It is plain to anyone reading Mr. Harrison's letter in *The Times* of this week that Positivists do not see themselves quite as others see them. One cannot be surprised. The "giftie" of seeing ourselves as others see us would belong rather to Relativists than Positivists. But Mr. FitzPatrick has been acquainted with the distinguished group of Comte's followers, and he must be aware that the "latest phases" of Comte became mystical and obscure, and left the safe ground of five-sense science, and undertook to deal objectively with the subjective aspect of life, and that in this departure he was not followed by all his followers, small as the distinguished group has always been. Was not Littré rather than Comte the Paul of the Positive system? And is not Mr. Frederick Harrison now a kind of melodramatic Athanasius, declaring the Positive polity with its human subjective synthetic side to be *ἀνάθεμα* with the awful primitive abstractions of Positive Science. One, indeed, can easily foresee fundamental divisions amongst the Comtists. But such divisions will never reach great dimensions through the numbers involved. To be a Positivist your brain must preponderate over your heart—a result obtainable either through much brain or little heart; and either of these alternatives will disqualify you for a wide religious success amongst the multitudes who compose humanity. Mr. Frederick Harrison has evidently much brain. The little Comtists whose qualification for the Positive philosophy consists in little heart are in even a more hopeless case than Mr. Harrison as to the prospect of attracting the attention of their divinity.

I am, Sir, yours truly,

Finsbury-circus, E.C., Sept. 15th, 1884. W. MORSON.

CONGENITAL SACRAL TUMOUR: A CORRECTION FOR THE "SYSTEM OF SURGERY."

To the Editor of THE LANCET.

SIR,—My attention has been called by Mr. Charles Hawkins to an unaccountable error in an article of mine in the "System of Surgery." May I ask you to allow me space to make the necessary correction? The passage is in vol. iii., p. 781, of the new (third) edition, in the article on Surgical Diseases of Childhood. Speaking of "congenital sacral tumour," and of the danger of operations on such tumours, I say, "This remark is illustrated by a preparation in St. George's Hospital Museum consisting of a number of irregular pieces of bone from a congenital tumour removed by Sir B. Brodie from the sacral region. The operation proved fatal." I cannot explain how such a misrepresentation could have crept into my work, since I had previously, in my book on "Surgical Diseases of Children" (second edition, p. 20) quoted from Mr. Hawkins's paper in the Path. Soc. Trans., vol. iii., p. 447, the following account of the real history of the case in Sir B. Brodie's words:—"Contrary to my advice, a surgeon made an incision into the tumour, which not only served no useful purpose, but left him in a worse state than he was before. Different cysts suppurated, discharging pus and adhesive fluid. Sometimes a collection of fluid and pus pressed on the rectum, occasioning a difficulty of expulsion of fæces, and then discharging its contents into the bowel. After this he was always in a state of greater or less suffering. He lost flesh, had occasional attacks of fever, and at last he sank and died." Thus my statement is erroneous in three particulars. 1. Sir B. Brodie far from having removed the tumour always advised the patient strongly to permit no interference with it. 2. The tumour was never really removed; the "other surgeon" only made an incision into it, when it was inflamed in consequence of the patient having fallen on it. 3. The pieces of bone in the preparation were removed, not during life, but by Mr. Hawkins in post-mortem examination.

I have thought it desirable to correct the error, which indeed ought never to have got into the text, or ought to have been corrected in the second edition of the System. The main conclusion, however, which I attempt to enforce in the article is unaffected by my blunder—viz., that such tumours should only be operated on when the surgeon believes that he can extirpate the whole tumour, and even then not without an adequate motive, since the operation is always a very formidable one.

I am, Sir, yours truly,

Great Cumberland-place, Sept. 11th, 1884. T. HOLMES.

THE EXAMINATION OF SURGEONS-MAJOR.

To the Editor of THE LANCET.

SIR,—Pressure of business has prevented my ere this asking you the favour of a space in your valuable journal for the few following remarks, in addition to the many already expressed, upon the subject of submitting surgeons-major in the army, over twenty years' service to a qualifying examination for promotion to the rank of brigade-surgeon (*vide* Army Circular, August 1st, 1884). The inadvisability of any examination for officers of such seniority appears to me apparent, having regard both to the prestige of the service and to the *amour propre* of the profession. This presumably is a military question, for which some imaginary precedent may supply the apology. Not even so much excuse or extenuation can be claimed for paragraph 9, by which I see it is intended that these elderly victims are literally, in more senses than one, to be put through their A B C, as I notice alphabetical clauses through two-thirds of the alphabet, terminating at letter O, which forms the culminating point of the whole absurdity. See paragraph 9, clause O: "Questions on operative surgery and practical medicine will also form part of this examination." But one parallel could be found for examining in such subjects professional men of a quarter of a century's seniority—viz., to subject all lieutenant-colonels in the army to an examination in the goose-step as a qualifying test of their fitness for promotion to the rank of colonel. Indeed, my allusion to the manners and customs of the feathered tribe appears suggestively applicable in tracing the present steps taken by the originators of this circular. This does not explain, however, the unaccountable deviation on the Director-General's part from the high order of intellect and capacity with which he has hitherto distinguished his present position, and if, contrary to his convictions, he has allowed himself to be influenced, the fact is only the more deplorable. The assignable object of these innovations is a desire to prove the efficiency of the department; but why delay that demonstration for twenty years? Were an examination necessary for such a purpose, its utility would be more marked at the commencement of an officer's career than towards its close. If a man has been efficient during twenty years' service, there is but scant necessity for proving the fact at the end of that term; and if he has hitherto been incompetent, it is late to remedy the evil. By all means subject officers to a rigid and most searching examination upon the widest range of professional subjects, between the ranks of surgeons and surgeons-major. From that much benefit would most probably accrue. But an officer practising for over twenty years is as unlikely to profit in the smallest degree from an examination as he is certain to be embittered against a service which could subject him to so unnecessary an indignity.

By paragraph 11 we are informed as to the nature and means of this inquisitorial revival. "It is to be in part by printed papers and in part *vivâ voce*. The Board will enter so far into the subject-matter of each head selected for *vivâ voce* examination as to show that the officer's knowledge has been fully tested." By all means. Only primarily let the Board's knowledge "be fully tested" as to its capability of pronouncing upon the practice and experience of officers who quite probably are as worthy of confidence as would be the opinion of those exalted personages forming the Board. By paragraph 12 I see this Board is "carefully to record all questions asked and answers received, and to send the record to the Director-General." But such a record must materially improve or deteriorate in merit according to the capacity and reliability of the source through which it is transmitted. To conclude: The papers will then be submitted to another Board, likewise of experienced officers, who in their turn are to pronounce upon the competence of the officer. For the second time the colouring given to that officer's proficiency would be deeply tinged by the prevailing hues of the Board's capability for transmitting the treble-distilled matter originally received from the unfortunate victim. He consequently must be largely dependent, not upon his own brains, but upon what could not obviously be a certain maximum quantity of that commodity in the possession of those relays of experienced individuals, always apparently unquestionable in their description. One naturally wonders who are to form this all-important tribunal. First, if civilians, an inevitable slur is cast upon the proficiency of the department. Secondly, if men in the same service, how can it be ascertained that they knew more about the subject than those they are pronouncing upon? Thirdly, will the presiding genii be called from amongst those fortunate mushrooms who spring suddenly to the surface and into office, having been grown in the forcing soil of an effete favouritism? Then, indeed, the whole injustice is not left without a coping-stone. But, as though there were any apprehension that the entire fiasco might not be rendered quite complete, we are informed that "the examination will be optional." Is it to be inferred from this that there is a lurking suspicion in the minds of the authorities that the veteran doctor would prefer bringing his grey hairs in sorrow, as a surgeon-major, to the grave, rather than face the alternative of being turned into a metaphorical shuttlecock, to be battledored from Board to Board, and from the A B C to the Omega of his profession? A very heartfelt sympathy with, and interest in, the department, gathered from personal experience in the services, must be my apology to you for so inconsiderately trespassing on your space.

I am, Sir, your obedient servant,

W. I. WHEELER, F.R.C.S.,
Ex-President of the Royal College of Surgeons, Ireland.

Dublin, Sept. 16th, 1884.

THE CHOLERA.

To the Editor of THE LANCET.

SIR,—The continued spread of cholera on the Continent makes it imperative on the part of medical officers to take extra precautionary measures to prevent its outbreak in this country, and especially in London. When cholera first appeared in France, the metropolitan authorities freely used disinfectants to street gullies and gratings, so that poisonous gases from putrefying matter were in a measure destroyed. It is not only gratings, gullies, dustbins, urinals, and receptacles for dust that require special attention at this time of the year, but the greatest danger exists in the branch drains leading from buildings to sewers in the streets. These are to some extent not under the control of vestries, and the inlets into sewers are often closed, and from these gases of the most poisonous nature are produced. In these branch drains disinfectants should be freely employed during the next two months. I am aware that many of the medical profession treat very lightly the theory that gases from putrefying matter are the principal agents in generating and transmitting zymotic disease; but to those who have investigated the question, it is not one of theory, but of fact. Previous to the cholera outbreak on the Continent, small-pox was very prevalent in London, but the free use of disinfectants as a preventive against cholera had the effect of stopping the small-pox epidemic.

I am, Sir, yours faithfully,

R. H. REEVES.

September, 1884.

LORD TENNYSON AND THE SURGEON.

To the Editor of THE LANCET.

SIR,—Even professing Christians are liable to imagine one another to be monsters of iniquity, and this is due to ignorance, for when placed on the same platform in some effort to benefit humanity, they learn to esteem one another. Probably Lord Tennyson is ignorant of doctors and their work, while Dr. Moxon may be ignorant of the incessant charitable visits of the Poet Laureate to his poor neighbours. It may be that Lord Tennyson was accustomed to distribute tracts in some village hospital, and met with a surgeon whose time did not allow him to pay sufficient, or, at least, desired, attention to the distinguished visitor. We ought never to judge hastily, and while surgeons may be doing everything in their power to relieve and cure their patients and deserve all honour for their sympathy and kindness, they must respect and honour the man who throws open his garden to the waifs of the street and at his own expense takes a crowd of little convalescents or street Arabs from the slums of London to indulge them with games and regale them with fruit on his own lawn, while he instructs them by reciting pieces of poetry and reading Gospel stories to them. I do not know anything of Lord Tennyson's deeds of charity, but no doubt his biographer will relate them. It is possible,

Digitized by Google

though improbable, that an intelligent man, full of sympathy and kindness for the poor and the afflicted, may be unable to appreciate the work done in hospitals, and may busy himself in establishing homes for the destitute and suffering that may be entirely under his own control. If both Dr. Moxon and Lord Tennyson are spending their lives in relieving the suffering and bringing joy to the mourner, a more intimate acquaintance will no doubt make them love one another.

I am, Sir, yours, &c.,

Sept. 1884. S. B. G. MCKINNEY, L.R.C.P. Edin.

BRITISH MEDICAL BENEVOLENT FUND.

To the Editor of THE LANCET.

SIR,—The late Sir Erasmus Wilson has munificently left the British Medical Benevolent Fund £5000, but as Lady Wilson takes a life interest in the whole of his property, this legacy of course is not payable until after her death.

I take this opportunity of bringing before the profession our urgent need of funds, for we are totally unable at the present time to help many of the deserving cases that come before us.

Subscriptions may be paid to the Treasurer, Dr. Broadbent, 34, Seymour-street, Portman-square, or to

Your obedient servant,

GEORGE P. FIELD,
Hon. Financial Secretary,

31, Lower Seymour-street, Portman-square, Sept. 10th, 1884.

"ORGANISMS IN CHOLERA STOOLS."

To the Editor of THE LANCET.

SIR,—Adverting to my letter and drawing of a fortnight back, I desire to add that the organism in question may flourish abundantly in dejecta possessing a distinctly acid reaction. It can hardly, therefore, represent the specific bacillus of Dr. Koch, however closely corresponding in respect to descriptions of the latter as yet published. Most observers would, I think, agree in referring my figures to those of a vibrio, admitting (what I find now doubted)[1] the validity of this particular form of bacterium.

I am, Sir, your obedient servant,

Bombay, August 19th, 1884. H. V. CARTER.

NEWCASTLE-ON-TYNE.

(*From our own Correspondent.*)

TYPHOID ON BOARD-SHIP FROM IMPURE WATER.

AT a meeting of the Sanitary Committee of the Middlesborough Corporation last week, the medical officer, Dr. Malcomson, reported the arrival of a Norwegian vessel, named the *Tross*, with typhoid fever on board. There were two cases, and one of the men had died. This case was a very bad one, and one or two of those who attended on the patients caught the infection. The ship had been disinfected, and an analysis of the water showed that it was little better than sewage, and had occasioned the outbreak. It was resolved to forward a copy of the medical officer's report to the Board of Trade, in order that captains of ships at Stettin may be warned against taking in a supply of water at that place for drinking purposes.

CHOLERA PRECAUTIONS ON THE TYNE.

Professor de Chaumont, medical officer to Her Majesty's Privy Council, has been visiting the Tyne with a view to ascertain what precautions have been taken to guard against the introduction of cholera into the port. As well as visiting the floating hospital at Jarrow, he has inspected the small-pox hospital on our Town Moor, the convalescent hospital for fever and small-pox at Byker, the fever hospital, &c., and he was shown the plans &c., for the proposed new and extensive hospital at Heaton for infectious diseases. He was supplied with details by our city authorities of the provision made by them for combating any infectious disease that may from time to time become epidemic. Professor de Chaumont, on leaving Newcastle, made a similar inspection of the neighbouring ports of Blyth and Tynemouth.

SANITARY MATTERS AT DURHAM.

In a previous letter, last June, I mentioned that the Corporation of Durham City had, in consequence of the remonstrance of their medical officer of health, agreed to provide a hospital for infectious diseases, and went so far as to select a site. The other day one of their aldermen actually succeeded in inducing the Corporation to rescind the resolution, notwithstanding that it is admitted, and notorious, that a greater necessity exists now than when the proposition was mooted and carried. It may be explained that the Corporation sits as the Urban Sanitary Authority, and that their opposition to their own scheme was based on the "needless expense" foundation, or, in other words, "the penny-wise and pound-foolish" system of economy. One of their own newspapers speaks of the procedure on the part of the Corporation as "the by no means uncommon exploit of advancing one step backwards." As a commentary on the strange proceedings of the Corporation, Dr. Barron, their medical officer of health has notified an outbreak of small-pox in the city, the district of Framwellgate having no less than fifteen cases. The Durham guardians have determined to give liberal out-door relief to all small-pox cases requiring it, in order to isolate the disease as much as possible and to keep it away from the workhouse; but probably the Local Government Board may have something to say about the absence of proper hospital accommodation for infectious cases in the city of Durham.

DEATH OF MR. JOHN PRATT, M.R.C.S.

The death of Mr. John Pratt, M.R.C.S., is announced. He was for many years in active practice in the city of Durham, and a few years since he received a public and valuable testimonial in recognition of his labours during the severe small-pox epidemic in Durham in 1872, when he attended over 700 cases. He was distinguished by his kindness to his poorer patients. Mr. Pratt entertained peculiar views in reference to the subject of vaccination.

Newcastle-on-Tyne, Sept. 16th.

GLASGOW.

(*From our own Correspondent.*)

SMALL-POX AND DIARRHŒA.

IN the health officer's report for the fortnight ending 30th August two important points are noted—a sudden increase in the death-rate from diarrhœa in the very young, and the disappearance of small-pox from our midst. With regard to the first, it is ascribed to the recent sultry weather, ending in a very severe electric storm. No fresh cases of small-pox had been discovered in the city for a month; "and as the last patient had been dismissed from the small-pox hospital on 23rd August, the city is now entirely free of that disease, and when it reappears it must be by importation from without." This result, one of which the citizens of Glasgow are to be sincerely congratulated, may very justly be said to be due to the untiring efforts of Dr. J. B. Russell and his energetic staff of sanitary officers, to check the epidemic.

OUTBREAK OF TYPHOID FEVER.

Another outbreak of typhoid fever, affecting chiefly the inmates and officials of our two infirmaries and the fever hospital, is at present under investigation. In the Royal Infirmary no fewer than thirty cases have occurred, three of the officials being among the number. At the Belvidere Fever Hospital one of the Royal Infirmary nurses has died from the disease. It is believed that the outbreak is in some way connected with the milk-supply; whether this is the case will doubtless be made clear in Dr. Russell's forthcoming report on the outbreak.

THE DRAINAGE SYSTEM OF NEW BUILDINGS.

At a recent meeting of the Dean of Guild Court, in Glasgow, the Lord Dean of Guild (Mr. William [illegible]) made the very sensible statement that, in his opinion, much advantage would be derived from the appointment of an officer whose duty it would be to survey the drains of new buildings and report on their sufficiency. Much good might be anticipated to flow from such an appointment. The Court sanctioned the erection of buildings [illegible]

Digitized by Google

standing that the drains should pass the officer's inspection, and should refuse a licenie for occupation till such officer's recommendation had been complied with, the present disgraceful state of our house-drainage system would soon be set right, so far as new erections are concerned. This is a matter which very closely touches the public health, and it is to be hoped that Mr. McEwen's suggestion will not be lost sight of.

IRELAND.

(From our own Correspondent.)

MEDICAL OFFICERS' SUPERANNUATION ACT.

DURING 1883 there were 83 Poor-law medical officers in Ireland receiving superannuation allowances. Of this number 61 were dispensary medical officers, 14 medical officers of workhouses, and in eight instances the medical gentlemen held both these appointments.

RICHMOND HOSPITAL, DUBLIN.

The whole nursing system in this institution has been pointed out by the Medical Board as very defective. There is no one to give the nurses instruction or to overlook their duties. The matron visits the wards during the day, but as she has to superintend three hospitals, it is impossible that she can see that the individual requirements of the patients are attended to. The Medical Board some time since suggested the appointment of a skilled lady nurse as superintendent, and it is satisfactory to find that the governors have at last consented to the arrangement, and that a meeting will be held on the 25th inst., in accordance with a notice given by Professor Stokes, when the salary and emoluments of a trained head nurse for the hospital will be considered.

OPENING OF BERKELY HALL, QUEEN'S COLLEGE, CORK.

Berkely Hall, which has been erected at a cost of some £9000, for the accommodation of Protestant students attending this college, was formally opened last week by the Lord Bishop of Cork Part of the cost was obtained on loan from the Board of Works, and among the contributors was Mr. Crawford, who gave £2500, leaving a debt remaining of upwards of £2000. The building, which contains forty bedrooms and grounds attached for the use of the students, has principally been erected owing to the exertions of the Dean of Residence, the Rev. Dr. Webster.

CORONERS AND MEDICAL WITNESSES.

A person recently died at the Hammam Baths, Dublin, and a medical gentleman being sent for found that life was extinct. The gentleman in question, Dr. McVeagh, very naturally expected that as he first saw the case, he would be the proper person to give evidence at the inquest, more especially as his name and address were taken by the constables in charge for that purpose. Another medical practitioner was, however, examined by the coroner, who was not sent for at the time of the man's death; and Dr. McVeagh complains, and with reason, of the want of courtesy and justice adopted by the coroner in this case towards the profession and himself.

Dr. Cameron, medical officer of health for Dublin, in his report for August states that the death-rate was unusually high, owing to the great mortality caused by diarrhœa, due to a considerable extent to the high temperature which prevailed.

The Dublin Corporation has arranged to add swimming baths to the baths and washhouses now being erected in that city.

The late Mr. James Gorman of Dublin has left £1000 to Jervis-street Hospital, £6000 to the Cabra Deaf and Dumb Institution, and £400 to the Mater Misericordiæ Hospital.

Dr. Fleetwood Churchill of Dublin died very suddenly from cardiac disease on the 6th inst. The deceased was highly esteemed and respected, and his untimely death is deeply regretted by a very large circle of friends and acquaintances.

Dublin, Sept. 15th.

VACCINATION GRANT.—Dr. Richards, of Birmingham, has, for the second time, received a Government grant for successful vaccination in the Edgbaston district of the King's Norton Union.

PARIS.

(From our own Correspondent.)

THE CHOLERA EPIDEMIC.

I HAVE nothing new to report in regard to the progress of the cholera in the south of France, and although it is still raging, it is doing so with diminished intensity, and is confined to the localities already named. Even in Spain the situation is about the same, but in Italy the epidemic is assuming alarming proportions, particularly in Naples, where, however, the mortality and the number of admissions have been somewhat on the decrease during the last two or three days. The incursion of the epidemic into these parts would seem to point to the futility of quarantines and "cordons sanitaires" so zealously carried out by the Italian Government.

Two cases were reported to have occurred in Paris, but, as usual, were found on inquiry to be nothing more than severe cases of seasonal diarrhœa, which, however, proved fatal. The deaths having occurred in a hospital, the same precautions were taken as are now prescribed for genuine Asiatic cholera.

Paris has not for a long time been so healthy as it is at present, and although the mortality is rather higher than that of the preceding week (985 against 932), it is about the average of the corresponding periods of the five previous years.

THE DISINFECTION OF ROOMS.

At the requisition of the Prefect of Police, MM Dujardin Beaumetz, Pasteur, and Roux performed experiments with the view of ascertaining what would be the best gas for disinfecting rooms in which patients suffering from contagious affections had sojourned. These gentlemen have come to the conclusion that sulphurous acid gas would be the most efficacious for such purposes; but instead of simply burning sulphur as is done in the barracks and military hospitals, they recommend the burning of the sulphur of carbon as being the least expensive and the least injurious to the furniture or articles of metal in the rooms.

A MONUMENT TO FRESNEL.

A rather interesting ceremony was performed last Sunday at Broglie (Eure) in the inauguration of a monument that has been erected in honour of Augustin Jean Fresnel, the illustrious physicist and member of the Institute, where he was born on the 10th May, 1778, and who died at Ville d'Avray, near St. Cloud, in 1827. The ceremony was presided over by the Duc de Broglie as Maire of the district, and was attended by the Municipal Council of the place, and delegates from the Academy of Sciences. Fresnel was the author of several important works on the phenomena of the dispersion, refraction, and polarisation of light, which led to the invention of "Phares à lentilles à échelons," or lighthouses with gradation lenses, which have rendered such material service to navigation.

Paris, Sept. 17th.

ITALY.

(From our own Correspondent.)

"*Sempre avanti, Savoia!*" (Ever forward, Savoy!)—the now historical exclamation of Queen Margherita when, on the eve of the royal visit to Sicily, the commandant of the *Duilio*, hesitating to put out into the stormy sea, took Her Majesty's opinion on the point—seems no less the watchword of King Humbert. When besought by his retinue of statesmen, soldiers, and physicians to pause in his pilgrimage through cholera-stricken Naples, he simply bows and continues his progress from bedside to bedside and from ward to ward. Before starting for the doomed city he received from the town council of Pordenone a memorial to honour with his presence the races about to come off in that Venetian town; and his reply, sent by telegram, has such a truly Roman ring that I cannot forbear quoting it in the original, if but to show how modern Italian, equally with ancient Latin, condenses into force and crystallises into epigram—"A Pordenone si fa festa; a Napoli si muore. Vado a Napoli." (At Pordenone they are merry-making; at Naples they are dying. I go to Naples.) And he was as

Digitized by Google

good as his word, though the danger to be encountered was as great as when he faced the Austrian fire at Custozza, or as when his father, while also a youth, had his hussar jacket riddled with seventeen bullets at Novara.

Courage is the requisite the Neapolitans are most in need of, and had they possessed but a fiftieth part of it as it lives and moves in the King, their mortality due to cholera would have been lessened in the same ratio. Of this none are more cognisant than the Italian physicians, two of whom, Dr. Paolo Mantegazza and Dr. Angelo Mosso, have written classical treatises on "La Paura [fear]; and its Influence in courting and aggravating Disease." The truth is that in sudden explosions of epidemic maladies the Southern are no better than the Northern races when the cry of "fire" has been raised in a theatre and the audience *en masse* makes for the door. Seventeen years ago the town of Albano, perched on the hills some fourteen miles from Rome, was the scene of a panic disastrous in the same proportion with that now decimating Naples. Rome had just been visited with cholera, and a few sporadic cases sent crowds of the inhabitants to the Alban Hills. One fugitive, who had certainly the germ of the disease in him before his flight, took refuge in the Cappuccini monastery just above Albano itself, and in twenty-four hours he died. The Capuchins, in their wisdom, interred his body wrapped in its cholera-stained garments at a spot within a few feet of the one well which supplied Albano with water! The consequences may be imagined. In two days the mortality in a population not numbering 7000 rose to hundreds. First one churchyard was filled, and then another had to be opened. The demon of terror seemed to have possessed the inhabitants. All fled who had the opportunity—ecclesiastics (with one or two honourable exceptions), shopkeepers, even the apothecary. The one physician who remained had more to do in exorcising fear than in any other treatment, and case after case came under his observation which (I quote his words) "died of sheer panic." Before the week was out there was no escaping from Albano, as the townsfolk of Castel Gandolfo on the one side, and those of Ariccia on the other, planted artillery at every point of egress and forced the Albanese to simmer in their own juice. The patrician Cardinal Altieri was among those who died at his post, which was immediately filled by another Monsignore. A powerful description of the scene presented by the usually slumberous Alban town during the August of 1867 was contributed by the late Mrs. Robert Macpherson to *Blackwood's Magazine* of the same year.

It must also be remembered that liability to panic in presence of a mysterious danger like that of cholera is intimately dependent on bodily well-being, as no one who has any knowledge of the *modus vivendi* in Southern Italy can fail to see. The population have no physical stamina, no moral resisting power. They sleep in overcrowded rooms—rabbit hutches rather. They are very ill-clad, in winter especially, flannel being well nigh unknown among them, while a clean skin means a cold skin, and the ablutions required by health are neglected accordingly. Then, their food is the least sustaining imaginable, nine-tenths of it being macaroni—that is, starch and water with a little lettuce or an olive doing duty as salad. Butcher's meat or aliments of any kind containing the proper proportion of nitrogen they seldom taste. In summer they consume large quantities of fruit, invariably unripe, as the produce of orchards is never allowed to ripen, lest it be stolen or annihilated by hailstorms. Their poverty is such that they can barely afford fuel enough to cook their macaroni, which is generally eaten half raw and conveyed to their mouths with their fingers from unutterably filthy tables unfurnished with plates or forks. In point of education or moral enlightenment they are pretty much as they have been for centuries back—ignorant, superstitious, at the mercy of every quack, medical, religious, or political. Such is the population which on every occasion of a cholera epidemic furnishes victims by the thousand, particularly in cities like Naples, where the water-supply has long been execrable, and where twenty-five years of constitutional freedom and parliamentary representation have not sufficed to bring back even the semblance of the magnificent reservoirs, aqueducts, and fountains of ancient Rome, republican or imperial.

Special treatment in cases of cholera is still undetermined in Italy. That which has proved most successful has been the hypodermic injection of water saturated with chloride of sodium—hypodermoclysis, as the Italian physicians call it (ὑπό, under; δέρμα, skin; and κλύζω, lave). This is simply an extension of Pacini's recommendation, practised also by Duchaussoy in Paris, and fully described in the "Report on the Results of the different Methods of Treatment pursued in Epidemic Cholera, addressed to the President of the General Board of Health," p. 13 (London, 1855). Pacini says:—"It is clear that the injection of salt water into the veins produces immediate reaction, but it is easy to see that the said reaction cannot be maintained so long as the intestinal transudation lasts. Everyone will admit that the primary care for a leaking wine barrel is not to keep filling it, but to make it tight; all the more is this the case in the human subject, where the vascular system has the power of refilling itself the moment the overflow ceases. So long as the patient is capable of swallowing astringent and antiseptic drinks, I do not believe the physician is authorised to practise those injections, since, besides being attended with risks, they are not absolutely required until the stage of apparent death, at least, in bodies presumed to be dead which present some return of warmth or some movement. The use of astringent and antiseptic beverages may be reverted to when reanimation manifests itself." Acting on these indications, Professors Perli, Amoroso, and Adinolfi, when in consultation one evening on a case of cholera collapse, practised hypodermoclysis according to Cantani's method. The operation itself was performed by Professors Perli and Adinolfi. In fifteen minutes the patient had absorbed a litre of water, and it was observed by the other physician present, as well as by a non-professional bystander, that the pulse became perceptible, the countenance, previously cadaverous in colour and feature, assumed something of animation, the anuria ceased, and a general improvement set in. During the night the amelioration was more and more pronounced, until the temperature touched fever point and the reaction commenced. The next morning the patient, though very weak, was comparatively well. Some interesting records of hypodermoclysis may be looked for from Naples.

Rome, Sept. 15th, 1884.

Obituary.

JOHN NETTEN RADCLIFFE.

WE deeply regret to have to announce the death after a long illness of this well-known member of the profession. Mr. Radcliffe was born in Yorkshire, and received his medical education at the Leeds School of Medicine, of which he was in later years practical teacher of anatomy and prosector; he also was for some time medical superintendent of the Hospital for the Paralysed and Epileptic in Queen-square. But it is in connexion with his labours on public health questions that Mr. Radcliffe secured his most lasting reputation. Having acquired some considerable experience on questions of health in the East during the Crimean campaign, he was selected by Mr. Simon in 1865 to prepare a report on the sources and development of the diffusion of cholera which then existed in Europe; a report was also prepared by him for the Privy Council office at about the same date on an outbreak of cholera at Theydon Bois; and it is certainly not too much to say that had Mr. Radcliffe never again written on the same subject his name would ever after have been identified with the standard literature on this important subject. The wide knowledge which Mr. Radcliffe obtained as to the topography of the East, and his immense power for accurate research, are brought out in a striking manner in these reports; indeed, from that date forward the Government invariably sought his aid in connexion with their investigations of Eastern epidemics in Europe. In 1867 followed Mr. Radcliffe's now famous report on cholera in the east of London, a report which embodied the results of an elaborate and impartial inquiry which led him to the conclusion that the terrible outbreak in question had been produced by the distribution of infected water from certain reservoirs of the East London Water Company. It was not long after the issue of this latter report that the Privy Council office secured the permanent services of Mr. Radcliffe as a medical inspector, and later

Digitized by Google

on, when the Local Government Board was formed, he was appointed to the post of assistant medical officer. From time to time he continued to issue reports on the prevalence of Eastern diseases, and these form by far the most valuable records on this subject which have ever been prepared in England. Thus, at the end of 1874 an exhaustive report was commenced, which recorded all the more important matters concerned with cholera diffusions in Europe during the preceding ten years. The report commences with the outbreak at Mecca in 1865; it traces its diffusion in such a way as to bring home to all who are open to conviction the fact that the disease had travelled by the various routes of human traffic and pilgrimage, and then it supplies a mass of details as to the various epidemic outbreaks in different European countries and towns, which of themselves give evidence of the immense amount of labour which was brought to bear upon the preparation of this important document. The last contribution of this sort consisted of an extensive report, issued in 1881, on the progress of Levantine plague in 1878-79, including the reappearance of the disease in Europe, and dealing also with the questions of quarantine in the Red Sea and of the sanitary regulation of the pilgrimage to Mecca. This report had a special value, insomuch as it effectually exposed the fallacies of quarantine regulations by land and sea.

But it was not only as an expert in the question of the distribution of Eastern diseases that Mr. Radcliffe must be regarded as holding one of the highest positions amongst workers in public health; he took his full share of the current work of investigations which were carried out in England to ascertain the causes of epidemics; his inquiries into the prevalence of erysipelas and pyæmia in connexion with faulty hospital construction and administration remain as standard contributions on this subject; and his very complete report on the means for preventing excrement nuisances in towns and villages has probably done more in this and other countries towards removing conditions of filth-poisoning than any other work ever issued. Mr. Radcliffe had also long been identified with the work of the Epidemiological Society, and after holding the office of honorary secretary for a long series of years, he was deservedly raised to the presidential chair in 1875. He was a constant and valued contributor to the pages of THE LANCET.

Some three years ago it was observed by his friends and colleagues that he was ailing in health, and then followed symptoms of paralysis which more than once compelled lengthened absences from official duties, and which early last year led to his resigning the official post he had so ably and honourably filled. Unfortunately, the progress of his illness prevented him from enjoying the rest he had so well earned, and latterly those of his friends who visited him were pained to see that a great light in the sphere of sanitation had evidently finally gone out. The actual symptoms which led to his death were of short duration. At the date of his resignation it was evident that his loss was much felt by all his colleagues, for, quite apart from his marked abilities, John Netten Radcliffe was the fortunate possessor of personal characteristics which had won for him a circle of true and sympathising friends, and which secured him against a single enemy.

The funeral took place last Wednesday at Highgate Cemetery, and was attended by several of his colleagues at the Local Government Board, by his brother, Dr. Charles B. Radcliffe, Dr. Glover, and other friends. Mr. Radcliffe leaves a widow and large family to mourn and deeply to realise their loss.

[illegible] GUISE WESTMACOTT, M.D., L.R.C.S., EDIN.

We [illegible] to have to record the death of Dr. Westmacott, [illegible] the late Henry Westmacott, Esq., of Cadogan-[illegible]. The deceased was born in London in 1811, [illegible] at the Medical College, Edinburgh, in 18[illegible] passed about three years in Paris, attending [illegible] hospitals, and made interesting studies in [illegible] of "calculi" for different professors, which were [illegible] at the time. After quitting Paris he settled in New York, where he practised for about ten years, distinguishing himself especially in the treatment of the eye, as is testified in works by Bouman and others; he then returned to London and set up in practice. He was delineator of Anatomy and Pathology for more than twenty years at King's College, consulting surgeon for the Paddington Provident Dispensary for upwards of thirty years, surgeon and surgeon-major in the London Scottish Volunteers, and also surgeon to the X division of the police for more than twenty years. The drawings in Gray's Anatomy, Druitt's "Vade Mecum," Obstetrical Works, and other publications, bear testimony to Dr. Westmacott's abilities. The deceased was twice married, and leaves three sons and five daughters.

Medical News.

APOTHECARIES' HALL. — The following gentleman passed his examination in the Science and Practice of Medicine, and received a certificate to practise, on Sept. 4th:—

Mathews, Frank Edward, York-place, Hill-rise, Richmond.

The following gentleman also on the same day passed the Primary Professional Examination:—

Bray, Percy Dean, Middlesex Hospital.

The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Sept. 11th:—

Barwise, Sidney, The Oaks, St. Paul's-road, Birmingham.
Blackwood, Frederick Martindale, Park-place, W., Sunderland.
Callender, Milton Romaine, St. Thomas's-crescent, Newcastle-on-Tyne.
Lynes, John, Argyll-road, Kensington.
Pedler, William Frederick, Albert Villas, Serpentine-road, Regent's-park.
Williams, Edward, Great Coram-street.

BERLIN oculists assert that the dust from the elevated railroads has added five per cent. to the profits of their profession.

BADLY ventilated school-rooms are blamed by the New York Board of Health as the cause of a large percentage of the cases of pulmonary consumption in the State of New York, where one death in every twelve is from that disease.

UNIVERSITY COLLEGE.—The annual dinner of the old and present students of the Faculty of Medicine will take place at the Freemasons' Tavern on Saturday, October 4th. Sir William Jenner will occupy the chair, and a large gathering of old University men is expected. Application for tickets (price 12s. each) must be made before October 1st to D. Poore or Mr. Stonham, F.R.C.S.

SUICIDE OF A SURGEON.—An inquest was held on the 13th inst. on the body of Mr. Charles Palmer, surgeon, of Yarmouth, who was discovered dead on a lonely part of the South Coast between Eastbourne and Birling Gap. Evidence was given that surgical instruments were found upon the deceased, an artery in whose groin had been skilfully opened. A verdict was returned of suicide while in a state of temporary insanity.

NEW COTTAGE HOSPITAL AT LLANDUDNO.—On the 4th inst. the foundation-stone of a new cottage hospital, to be erected as a memorial to the late Mrs. Dr. Nicol, who was the founder of the movement, was laid by Lady Augusta Mostyn Gloddaeth. When completed, the hospital will contain twenty beds, besides convalescent ward, operating room, spacious hall, mortuary &c.; and the outlay will be £2960, upwards of £1500 of which sum has been subscribed.

THE EXAMINATION OF WATERS.—A Blue-book has been issued by the Local Government Board containing the second report of Dr. R. Angus Smith, one of the inspectors under the Rivers Pollution Prevention Act, 1876, on the examination of waters. Dr. Smith states that the Thames waters show distinct inferiority to the hill waters both as to hydrogen and transformation of gelatine. He had concluded from the experiments he had made that the water of the Thames, even after being filtered, was less pure than the waters of the uplands of England. That truth, he adds, could scarcely be called new, but the difference might be subjected to measurement and put into the form of figures so far as certain qualities were concerned. He could not, however, measure in the same way the effect upon health.

SMALL-POX IN THE ARMY AND NAVY.—A return published on the 6th inst. of the number of deaths from small-pox in the army and navy during each of the years from 1860 to 1882 shows that in 1860, with an average annual strength of 203,017, there were 30 deaths in the army, or a ratio of 0·15 per thousand. This percentage was increased to 0·22 in the following year, but since that time has been greatly reduced, the ratio in several years being only ·01 per 1000. In the navy the ratio per 1000 in 1864 was as high as 0·51, but since that time has not exceeded 0·26 per 1000, while in 1877 and 1878 there were no deaths returned from this malady.

SOCIAL SCIENCE CONGRESS.—The twenty-eighth meeting of the Social Science Congress commenced at Birmingham on the 17th inst., when the inaugural address was delivered by Mr. Shaw-Lefevre, M.P. The Congress is divided into five departments, as follows:—Jurisprudence and Amendment of the Law—President, Mr. John Westlake, Q.C., LL.D. Education—President, Mr. Oscar Browning, M.A. Health—President, Dr. Norman Chevers. Economy and Trade—President, Viscount Lymington, M.P. Art—President, the Right Hon. A. J. Beresford Hope, M.P. The weather being favourable, the gathering promises to be more than ordinarily successful.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—The monthly meeting of this association was held on the 11th inst., Dr. M'Nicoll, presiding. Dr. F. Vacher called attention to the extent and limits of the powers given in the sections of the Public Health Act, 1875, which empower medical officers and inspectors of nuisances to deal with bad food. He pointed out that the Act conferred powers which it would be impossible to dispense with, and which, though less complete than they might easily be made, were as a rule fairly efficient and easily worked. The subject will be further discussed at the next meeting of the Association.

ARMY NURSES.—A Royal Warrant has just been promulgated, by which the provisions of the warrant of June 10th, 1884, relative to the nursing staff of the army, are amended. By the new warrant the pay of lady superintendents of nurses is to be £150, increasing £10 annually till it reaches £200. The lady superintendent of the Royal Victoria Hospital at Netley is to receive an additional allowance of £50 for training the nursing staffs and carrying out such duties as the director-general of the Army Medical Department may direct from time to time. A senior nurse, acting as superintendent, is to receive pay of £20 a year in addition to her salary. The lady superintendents at the Victoria Hospital, Netley, and at Herbert Hospital, Woolwich, shall, on relinquishing their duties, receive retired pay at the rate of 20 per cent. of their salaries after ten years' service, rising by 2 per cent. for each additional year of service up to a maximum of 50 per cent.

THE NIGHTINGALE FUND.—The annual meeting of the Council of the Nightingale Fund was held last week at the "Nightingale Home," St. Thomas's Hospital, Lord Houghton in the chair. The report stated that the number of probationer nurses remaining in the School at St. Thomas's on the 31st December, 1883, was 31, of whom 12 were special or lady probationers and 19 nurse probationers. From the opening of the School in June, 1860, to the end of 1883, a total of 739 candidates had been admitted, and 437 had left the School, after completing a year's training, as certified nurses. The number of failures was exceptionally large; they were due mainly to deficient physical strength. The Committee noted, as indicating the progress made in Training Schools for Nurses in connexion with other hospitals, the opening of the new building of the Westminster Training School and Home for Nurses, in connexion with the Westminster Hospital, of which Miss Pyne is the lady superintendent; the addition of largely increased accommodation for both probationers and nurses at St. Mary's Hospital, Paddington, where a successful School had been established under the matron, Miss Williams; and the opening of a Home for the same purpose at the St. Marylebone Workhouse Infirmary, Notting-hill, of which Miss Vincent is the matron. The abstract of accounts showed an income of £3881, and an expenditure of 1907, leaving a balance of £2074 in hand.

A TABULAR VIEW OF THE DAYS AND HOURS OF THE INTRODUCTORY LECTURES

*To be delivered at the different Medical Schools.**

	Lecturers.	Days and Hours.
St. Bartholomew's Hospital	(No Lecture)	—
Charing-cross Hospital	(No Lecture)	—
St. George's Hospital	Dr. Champneys	Oct. 1st 4
Guy's Hospital	(No Lecture)	—
King's College	Rev. H. Wace, D.D.	,, 1st 4
London Hospital	——	,, 1st 8
St. Mary's Hospital	Dr. Lees	,, 1st
Middlesex Hospital	Dr. D. W. Finlay	,, 1st 3
St. Thomas's Hospital	Sir J. Risdon Bennett	,, 1st 3
University College	Dr. W. R. Gowers	,, 1st 4
Westminster Hospital	Dr. Hughes Bennett	,, 1st 3
Mason's Science College	Prof. Paynting	,, 2nd
University College, Bristol	(No Lecture)	—
Queen's College, Birmingham	Dr. Sawyer and Dr. Fletcher	,, 1st
Sheffield School of Medicine	Mr. Birks	,, 1st 5
Leeds School of Medicine	Dr. Michael Foster	,, 1st
Edinburgh University	(No Lecture)	—
Glasgow University	Prof. Leishman	,, 28th
Anderson's College, Glasgow	Dr. Thomas Barr	,, 28th
Glasgow Royal Infirmary and School of Medicine	John Glaister, M.B.	,, 28th

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BATES, CHARLES POPE, M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the Ramsey Urban Sanitary District.

BEATLEY, WM. CRUMP, M.D.Durh., M.R.C.S., late Senior Assistant Medical Officer to the Somerset County Asylum, has been reappointed Resident Medical Officer to the Newcastle-upon-Tyne Dispensary.

BRADSHAW, THOMAS R., M.D.Dub., M.R.C.S., has been appointed Assistant House-Surgeon to the Liverpool Northern Hospital.

BROWN, JAMES, L.R.C.P.E. &c., has been appointed Honorary Physician to the Bognor Convalescent Home.

CAMPBELL, JAS. J., M.B., C.M., has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

DALZELL, J. KENNEDY, M.B., C.M., has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

EVANS, WILLIAM, L.R.C.P.Ed., M.R.C.L., has been reappointed Medical Officer of Health for the Anglesey United Sanitary District.

EWBANK, FRANCIS, M.R.C.S., L.D.S., L.S.A.Lond., has been appointed Dental Surgeon to St. Bartholomew's Hospital, vice Coleman, resigned.

FALKINER, N.M., M.B., has been appointed Joint Lecturer in Chemistry to Carmichael College.

HARDWICKE, Dr. W. W., has been appointed Medical Officer of Health to the Borough of Harwich. Also Medical Officer of Health to the Harwich Port Sanitary Authority, both vice A. Kinsey Morgan, resigned.

HOBLEY, J.H., L.R.C.P.Lond. &c., has been appointed Medical Superintendent of Quarantine, Southampton, vice Bencraft, deceased.

HOPE, HENRY, L.R.C.P.Ed., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer of Health for the Southampton Port Sanitary District, vice Bencraft, deceased.

HOWARD, THOMAS, M.B., C.M., has been appointed House-Physician to the Royal Infirmary, Glasgow.

HUNTER, R. R., M.B., C.M., has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

JEFFERY, EDWARD, M.D.Aberd., M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the Lowestoft Urban Sanitary District.

KENDALL, THEO. M., B.A.Sydney, L.R.C.S., L.R.C.P., L.M., has been appointed Assistant-Surgeon to St. Vincent's Hospital, Sydney.

LYS, FRANCIS DANIEL, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer of Health for the Wareham and Purbeck Rural Sanitary District.

MCMUNN, J. A., M.B., C.M., has been appointed Medical Officer to the Odd Fellows, Rechabites, and Parish of St. Anne, Alderney, Channel Islands, vice W. A. Ross, M.R.C.S., resigned.

MARSHALL, WILLIAM, M.B., C.M., has been appointed House-Physician to the Royal Infirmary, Glasgow.

MASON, HENRY, M.B., C.M., has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

MUIRHEAD, ISLAY B., M.B.Glas., has been appointed Medical Officer for the Second District of the Malling Union.

PARTRIDGE, SAMUEL, M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the Darlaston Urban Sanitary District.

PEACOCK, ALEX., M.B., C.M., has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

RANSON, WILLIAM EDWARD, M.R.C.S., has been appointed House-Surgeon to the Staffordshire General Infirmary, vice Frank Marsh, F.R.C.S.E., resigned.

RUSSELL, FRANK, M.B., C.M., has been appointed House-Physician to the Royal Infirmary, Glasgow.

Digitized by Google

SCOTT, ROBERT, M.B., C.M., has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

SMITH, WILLIAM HARVEY, M.R.C.S., has been appointed Medical Officer for the Meriden District and the Workhouse of the Meriden Union.

STARK, J. NIGEL, M.B., C.M., M.R.C.S., has been appointed House-Physician to the Royal Infirmary, Glasgow.

WADE, A. B., M.B.Edin., &c., has been appointed a Medical Officer to the Odd Fellows, Southampton, vice Bencraft, deceased.

WELCH, R., L.R.C.P.Ed. &c., has been appointed Medical Officer to the Southampton Workhouse. Also a Medical Officer to A.O.F., Southampton, both vice Bencraft, deceased.

WILSON, FRANK, M.B., C.M., has been appointed one of the Parochial Medical Officers for the Burgh of Paisley, vice Dr. Whitehead, resigned.

Births, Marriages, and Deaths.

BIRTHS.

ARCHER.—On the 16th July, at Moonta, South Australia, the wife of R. Kendray Archer, M.R.C.S., of a son.

BAKER.—On the 15th inst., at Lawn-terrace, Dawlish, the wife of A. De Winter Baker, L.R.C.P.Lond., M.R.C.S., of a son.

BEEVOR.—On the 10th inst., at Harley-street, the wife of Charles E. Beevor, M.D.Lond., of a son.

CADELL.—On the 13th inst., at Castle-terrace, Edinburgh, the wife of Francis Cadell, F.R.C.S.Ed., of a daughter.

CLARKE.—On the 4th inst., at 21, Lee-terrace, Blackheath, the wife of Ernest Clarke, M.B., B.S., of a daughter.

DAVISON.—On the 13th inst., at Langton House, Battle, Sussex, the wife of Rashell Davison, M.D., of a son.

DE MERIC.—On the 14th inst., at Weymouth, the wife of Staff-Surgeon E. V. De Meric, R.N., H.M.S. *Iris*, of a daughter.

PICKERING.—On the 13th inst., at Hargrave-terrace, Terenure-road, Dublin, the wife of T. H. Pickering, M.R.C.P., of Monte Carlo, of a daughter.

SEYMOUR.—On the 15th inst., at Sangora-road, New Wandsworth, S.W., the wife of J. R. Seymour, L.R.C.P., M.R.C.S., &c., of a son.

STARKIE.—On the 14th inst., at Sussex-street, Warwick-square, London, S.W., the wife of Richard F. Starkie, M.D., of a daughter.

WATSON.—On the 9th inst., at Wellfield, Penistone, Yorkshire, the wife of Alfred M. Watson, M.D., of a son.

WILLIAMS.—On the 10th inst., at Newbeggin, Richmond, Yorkshire, the wife of Howell Williams, L.R.C.P. and M.R.C.S., of a son.

MARRIAGES.

EMERSON—WILLIAMS.—On the 10th inst., at St. Peter's Church, Hammersmith, by the Rev. A. Tidcombe, George Augustus Emerson, M.B., C.M.Ed., I.M.D, to Edith Rachael, second daughter of the late T. R. Williams.

FREEBORN—LAWTON.—On the 10th inst., at St. Olave's, York, John Charles Richard Freeborn, M.A., M.R.C.S., to Emily Sarah, eldest daughter of the late George Lawton, Esq., Proctor of York.

GILLON—NOCK.—On June 5th, at St. Paul's Cathedral Church, Wellington, New Zealand, by the Rev. Fancourt George Gore Gillon, M.B., C.M., to Cathreen, youngest daughter of Joseph Nock, of Westminster, Frankley, near Birmingham.

HERMAN—GIBBINGS.—On the 5th inst., at St. Peter-the-Less, Chichester, by the Rev. W. D. Cowley, D.D., George Ernest Herman, M.B., M.R.C.P., of 7, West-street, Finsbury-circus, to Emily, fifth daughter of the late Thomas Gibbings, of Chichester.

HOSKYNS—IVESON.—On the 11th inst., at the Parish Church of Crich, Derbyshire, by the Rev. F. W. Moore, Vicar of All Saints, Duffield, assisted by the Rev. R. J. Hope, M.A., uncle of the bride-groom, Edward John Hadderton Hoskyns, Surgeon, Belper, to Rosalie Marie, eldest daughter of T. G. Iveson, Esq., C.E., of Crich.

RECKITT—YOUNG.—On the 3rd inst., at St. Paul's, Hammersmith, by the Rev. Cecil S. Pollard, Edward Bass Reckitt, L.R.C.P.Ed., of Boston, Lincolnshire, to Ellen Isabella, eldest daughter of the late Charles Vernon Young, 49, Aynhoe-road, West Kensington-park.

SHAW—SPALDING.—On the 2nd inst., at St. Helen's Church, Ore, near Hastings, C. Knox Shaw, L.R.C.P., M.R.C.S., to Ellen Elizabeth, daughter of Thomas Spalding, Esq., of Ore Place, Ore.

VACY-ASH—MAXWELL.—On the 11th inst., at St. Barnabas' Church, Kensington, Surgeon-Major R. Vacy-Ash, M.B., to Eliza, eldest daughter of Major T. Maxwell.

WALTER—WHITWORTH.—On the 4th inst., at Ulverston Parish Church, by the Rev. W. Crowther, M.A., Rector of Norton, Kent, uncle of the bride, assisted by the Rev. E. H. Aldridge, M.A., Vicar of Facit, Rochdale, and the Rev. C. W. Bardsley, M.A., Vicar of Ulverston, William Walter, M.A., M.D., of 20, St. John-street, and Hilton-park, Manchester, eldest son of Dr. Walter of Dublin, to Gertrude Phœbe, only daughter of the late Edward Whitworth, Esq., of the Grange, Whitworth, near Rochdale.

DEATHS.

CADE.—On the 28th ult., at Spondon, Joseph Wright Cade, M.R.C.S., L.S.A.Lond., late of Breaston, Derbyshire, in his 88th year.

GOODALL.—On the 10th inst., at Southborough, Kent, William Preston Goodall, F.R.C.S., formerly of Birmingham, aged 50.

HAMILTON.—On the 10th inst., Alfred Hamilton, formerly Surgeon to the London Hospital.

KING.—On the 4th inst., at Torquay, David Alexander King, M.B., M.R.C.P., late of 26, Harley-street, in his 28th year.

PATERSON.—On the 7th inst., at Gainsboro', suddenly, Robert Haldane Paterson, M.R.C.S., L.R.C.P., aged 34.

SHARP.—On the 7th inst., George Wyatt Sharp, F.R.C.S.E., son of the late Henry Lockyer Sharp.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE BACILLUS OF THE "PERIOD."

THE Italians, slightly jealous of the temporary superiority of the Germans in pathological research, particularly in the investigation of the cholera microbe, are relieving themselves in a little satire, of which the following quatrain, freely translated, may be taken as a specimen:—

"Dr. Koch—with surprise it doth fill us—
Is hailed as a medical Solon,
For proving the *comma* bacillus
Is often attached to the *colon*."

Obstetrics.—Our correspondent must not be too proud to state the facts. He cannot claim the full consideration of a qualified and registered practitioner, but he will not find any medical man insensible to the facts.

Major Upton.—The best plan would be to advertise, when no doubt applications would be received from which a selection might be made.

Dr. Squire.—The matter is under consideration.

PECULIAR FORM OF PLACENTA CAUSING DELAY IN THE THIRD STAGE OF LABOUR.

To the Editor of THE LANCET.

SIR,—I send the following particulars, trusting they may be of interest.

Mrs. W——, aged thirty-five, multipara, was confined on Sunday, Sept. 7th. The child was born at 4 P.M., and after waiting the usual time, "expression" of the placenta was tried, after Credé's method. The uterus was well contracted under the hand, but appeared somewhat enlarged. After adopting this procedure for about twenty minutes, and finding that the placenta was not expelled, a vaginal examination was made. The placenta was found well down in the vagina, the examining finger almost reaching its inner extremity. Gentle traction on the cord was now resorted to; and, finding this useless, after a while strong traction was made, but all to no purpose. Being puzzled at this prolonged retention in the vagina, a more thorough search for its cause was about being made, when the placenta was suddenly expelled, to be followed almost immediately by a supplementary one, to which it was attached by a fibrous cord about four inches in length. On examination the first placenta was found to be very large, and of the "battledore" variety. The second, or supplementary, mass was rudimentary in structure, and appeared to be a quarter the size of the placenta proper. The fibrous band which connected them was pretty strong, and on carefully examining it a vascular communication between the placentæ was discovered running through its centre. This anomaly explained the retention of the placenta proper in the vagina, it being held there by its communication with the supplementary mass, which had not yet been expelled from the uterine cavity.—I am, Sir, yours truly,

Middlesbrough, Sept. 13th, 1884. WILLIAM BAXTER, M.D.

TEMPERANCE AMONG RAILWAY SERVANTS.

ALL men with grave responsibilities, whether railway servants or professional men, should be conspicuously sober. It is gratifying to know that the United Kingdom Railway Temperance Union numbers 5470 members. This is a great security against railway accidents.

Mr. Hugh Stott.—The question is strictly legal, and can only be answered by a legal authority, equally recognised by both parties.

Mr. G. Rivers.—See the leader on Cholera in our present number.

M.D.—Next week.

"WHAT IS A MINIM?"

To the Editor of THE LANCET.

SIR,—In reply to this query of Lieut.-Col. J. Herschel, C.E., I beg to state that in the Appendix to the British Pharmacopœia a minim is defined as being "0·91 grains of water;" it is about $\frac{1}{10}$, not $\frac{1}{8}$, of a grain, and is the 480th part of a fluid ounce, which is there defined, "the measure of 1 ounce, or 437·5 grains of water." The fluid ounce of water at 62° F. weighs 1 ounce avoirdupois, and the fluid drachm 54·68 grains, not 57 grains, as stated by your correspondent to be its "proper weight." It is true that the 128th (i.e., $\frac{1}{8}$ of $\frac{1}{16}$) of the old wine pint, which was the measure of 7289·72475 grains troy, gives 57 grains (nearly) as the weight of the old fluid drachm. This 57 grain fluid drachm, until the imperial measure was recognised by the London Pharmacopœia of 1836, was the one used in medicine. Since then the 54·68 grain fluid drachm has been in use. Your correspondent has proved his minim glass to be correct. My authorities for the above are the British Pharmacopœia and Gray's Supplement to the Pharmacopœia, edited by Dr. Redwood (also editor of the last British Pharmacopœia). It often causes great trouble to pharmacists, particularly in preparing solutions for hypodermic injection, that their units of weight and of measure, the grain and the minim, are not easily convertible; their ratio is 960:875. I learn with sorrow for coming pharmacists that the same system of weights and measures is to be continued in the next British Pharmacopœia. Although nearly every other civilised nation recognises the use of the metric system for dispensing medicines, the British Pharmacopœia is to be produced with the cumbrous weights as before, of which the grain is not even the aliquot part of an ounce, because, it is feared, the doctors and the chemists do not understand the metric system. I am, Sir, your obedient servant,

New Cavendish-street, W., Sept. 6th, 1884. WM. MARTINDALE.

To the Editor of THE LANCET.

SIR,—If Lieut.-Col. Herschel refers to the last edition of the British Pharmacopœia he will find, at page 402, a table showing that a minim is the $\frac{1}{7680}$ part of a gallon, by which is intended the imperial gallon, as the preface informs us. Another table on the same page states that a minim is the measure of 0·91 grain, and a fluid drachm of 54·68 grains of water (at 60° F.). As this agrees with the weight obtained experimentally by your correspondent, it is unnecessary to imagine a systematic blunder in the graduation of minim glasses; but (if the figures are correctly quoted) there certainly appears to be an error in Thompson's Conspectus.—I am, Sir, yours faithfully,

Moorgate-street, Sept. 5th, 1884. F. R. WALTERS, M.D., F.R.C.S.

To the Editor of THE LANCET.

SIR,—If it is remembered that at the introduction of the British Pharmacopœia the imperial measure of 20 oz. to the pint and the imperial pound of 16 oz. were adopted, whilst the grain weight was left intact, the discrepancy noticed by Lieut.-Col. Herschel disappears. He states that the imperial gallon weighs 10 lb., or 70,000 grains; and if he will work this down into pints, fluid ounces, drachms, and minims, he will find the latter weighs 0·91 grain. His practical weighing shows that the measure he used was perfectly marked. All graduated measures should be thoroughly tested, to see that the fluid ounce of water weighs exactly one ounce avoirdupois, and that the drachm (or sixty minims) weighs 54·68 grains. I am, Sir, yours obediently,

Sept. 5th, 1884. A COUNTRY DOCTOR.

To the Editor of THE LANCET.

SIR,—A minim is the 480th part of a fluid ounce. Since a fluid ounce (the 20th part of a gallon) of distilled water at 60° F. weighs 437·5 grains, a minim is the 480th part of an ounce, therefore a minim would weigh 0·91152 of a grain, and the fluid drachm of sixty minims would weigh 54·69126 grains. Such being the case, the minim measure to which Lieut.-Col. Herschel refers was perfectly correct—more so than the generality. In the volume on "Materia Medica and Therapeutics" of Bassell's Manuals for Students of Medicine, page 17, Dr. J. Mitchell Bruce gives the weight of the minim as being 0·91 of a grain.

I am, Sir, yours faithfully,

Wilton, Sept. 8th, 1884. WALTER PIPPETTE.

MISSING INSTRUMENTS.

To the Editor of THE LANCET.

SIR,—During my absence a stranger called at my house and was admitted to my study, to write a letter to me about his wife. This same man is in custody at [illegible], and on him have been found an ophthalmoscope and [illegible]. Neither of these is mine; but perhaps some [illegible] will be able to know where he may possibly find his [illegible]. I am, Sir, yours faithfully,

[illegible] HENRY PATRICK, M.D.

Gloucester-road, [illegible], Sept. 8th, 1884.

THE FRIENDLY SOCIETIES' INSTITUTE, BATH.

A VERY sensible and reasonable letter appears in the *Bath Argus* of Sept. 11th, against what the writer considers the arbitrary action of the committee in thinking of dismissing the medical officer without consulting the members.

Mr. W. H. Day.—The point made is ingenious, but will not avail in the present state of the law, which draws a clear distinction between vaccination and inoculation, which science does also, in spite of the theory alluded to. Moreover, in any case the *law enjoins* vaccination.

W. J. M. (Sutton).—Was the certificate sent direct from the office to the medical man, asking for the information; or was it brought to our correspondent, and the application made by the parties claiming?

M.D.—The question is not clear.

WANTED, A DIAGNOSIS.

To the Editor of THE LANCET.

SIR,—Can any of your readers give me a diagnosis and the line of treatment to be adopted in the following cases.

A patient of mine, a gentleman aged thirty-six, chief clerk in a merchant's office, has for the past three or four months noticed a gradually increasing weakness in the right hand and an inability to hold the pen firmly between the fingers. At the present time he writes his letters with considerable hesitation. There is no cramp, no spasmodic or irregular jerking of the muscles of the fingers, none of the usual symptoms of a typical case of "writer's cramp," an affection which this occupation would naturally lead one to suspect. There is simply muscular weakness, perhaps it might almost be called muscular incompetence. But the curious point is that his brother, aged thirty-two, whom I have seen, living in a different part of the country, and whose duties do not require him to write more than a score or two lines a day, is troubled with the same affection. In neither case is there muscular wasting, nor was it preceded by lightning pains. There is nothing in the family history bearing upon the case, and neither of them had had any serious illnesses in former years. The elder of the two is a total abstainer and non-smoker, the younger is a moderate smoker. Physically they are healthy and strong. The fact that in the case of the younger brother the affection is not traceable to over-use of the muscles leads one to suspect that in the one case, if not in both cases, the origin may be spinal, and that there may be some want of controlling power over the muscles. In the way of treatment, rest and strengthening have been tried, but with little or no improvement. Galvanism has not yet been resorted to. Can you give me any suggestion as to the cause, pathology, and treatment? I am, Sir, yours [illegible],

September 16th, 1884. [illegible].

Z.—We do not remember such a point being raised in a law [illegible]. The error would have to be very serious.

Mr. John Brown.—We do not recommend individual physicians. The knowledge of gout is not monopolised by one man nowadays.

R. T. D. and others.—The card is beneath notice.

J. T. P.—We do not remember the appearance of the receipt mentioned.

"NON-QUALIFIED, EXCEPT AS TO SURGERY."

To the Editor of THE LANCET.

SIR,—I shall be obliged by your letting me know at your convenience if there is any authority in the profession to which a member of the public might properly apply for opinion on a prescription. I desire such an opinion on a prescription given by a [illegible] practitioner, and acted on (but with unsatisfactory effect), in order to ascertain whether it is a competent prescription, the person who wrote it being a non-qualified practitioner, except as to surgery.

I am, Sir, yours [illegible],

Sept. 8th, 1884. [illegible] M.

*** There is no such authority. The fine distinction between qualifications is rather a legal refinement than anything else. It is kept up in the interest of the numerous separate corporations which, [illegible] in asserting their right to be maintained by the profession [illegible] the reasons for their separate existence have been abolished, [illegible] the result of entailing offensive charges of incompetence, as above, on [illegible].

A. T. Brand, M.D.—See the articles on Home Health [illegible] which appeared in THE LANCET of Aug. 9th and 23rd.

Richard James.—A work on the subject mentioned may be obtained from any of the medical booksellers.

Mr. J. G. Fennell.—We regret we cannot afford the information desired.

"SKILLED NURSING."

To the Editor of THE LANCET.

SIR,—So many people have written to me about the letter which appeared, signed "E. Faithfull," in THE LANCET a fortnight ago, that I should feel very grateful if you would kindly state in your next issue that I am not the writer of it, for I should scarcely wish to endorse the same. I have been in Scotland since my return from the United States, finishing my volume, "Three Visits to America," which will be brought out here and in New York in October.

I am, Sir, yours very truly,

Bryanston-street, W., Sept. 11th, 1884. EMILY FAITHFULL.

Digitized by Google

Inquirer.—No such appointment is recognised either by the Public Health Act or the orders of the Local Government Board, and that Board object to the delegation of sanitary work to a deputy. If a medical officer of health is temporarily unable to perform his duties, the appointment of a substitute is sanctioned; but if an officer is not capable of performing his duties, he is expected to resign.

M. M. M.—Medical men are supposed to attend each other without money considerations; but there are circumstances of distance, inconvenience, &c., which make it reasonable to offer a fee, or to take other means of showing that medical kindness is appreciated by medical men.

Justice Campbell.—There is no particular work on the subject, but the matter is treated in most books on Diseases of the Skin.

Enquirer shall receive a reply next week.

Mr. Crosbie.—The statement has already appeared in THE LANCET.

INFANTILE CIRCUMCISION.

To the Editor of THE LANCET.

SIR,—I frequently perform the operation of circumcision on new-born infants—that is to say, on infants eight days old. It forms part of the religious ceremony observed on initiating male children into the "Hebrew Faith," and is rarely, if ever, neglected. My experience may therefore be of use to "Foreign Practitioner," who seeks information on the subject in your issue of the 6th inst. Your able answer gives a clear description of the principal points of the operation; but, if I may be allowed, to add a few remarks, I think that it will be found that the operation is not so formidable as it may at the outset appear. When the prepuce is drawn in front of the glans, as you describe, I use a shield to grasp it, which consists of a tolerably thick silver plate, having a slit in it narrowing from the circumference to the centre. The prepuce is forced into this slit, and the shield is applied in a slanting direction from above downwards, as mentioned in Erichsen's Surgery, vol. ii. The advantage of this shield is that it is light, easily adjusted, and remains in its place without the aid of an assistant. Then, instead of slitting up the mucous membrane, I tear it along the dorsum with my thumb nails, which, to prevent slipping, I cut into points, so that they easily retain their retain it. In this way I tear no more than is sufficient to allow of the membrane being pushed well back, so that the glans are thoroughly exposed. I next apply a piece of boracic lint tightly round the penis behind the glans, as you describe. But I use no stitches of any kind in infants, nor even in children of two or three years of age; and my experience is that the edges come together of themselves, and the wound heals rapidly, usually in three or four days, without the necessity for further interference, beyond attention to cleanliness and the observance of the simplest rules in surgery. To guard against the lint being disturbed I bandage the child's knees and legs together with a napkin for a few hours after the operation. Performed in this way, I have never met with the slightest difficulty, and have always had most satisfactory results.—I am, Sir, yours obediently,

Wearrington-gardens, Sept. 8th, 1884. M. CLIFFORD, M.R.C.S., &c.

To the Editor of THE LANCET.

SIR,—In your issue of the 6th inst. "Foreign Practitioner" asks for information respecting the operation of infantile circumcision. In reply you recommend sutures to be used, and I believe the standard works on surgery do the same; but I am convinced it is a mistake. I have performed the operation on more than forty boys within the last two years, and rarely pass a week now without a case. At first I inserted sutures, but soon discontinued doing so, finding so much irritation and suppuration arise therefrom, besides leaving when healed a ragged and thickened edge to the remaining portion of the prepuce; and being, as I believe they are, worse than useless, it is as well to avoid the unnecessary pain caused by their insertion. In my last thirty cases I have not inserted a single suture, and they have all done well; neither have I used an anæsthetic of any kind, and have only dressed the wound with lint first wetted with cold water for three or four days, and then with olive oil. If any undue hæmorrhage take place (which is very seldom) after the operation, a drop of the solution of perchloride of iron has succeeded in, where the cold water has not proved sufficient.

I am Sir, yours truly,

Birmingham, Sept. 9th, 1884. A. G. WILKINSON.

A Constant Reader.—The questions are not free from difficulties. They involve not only the law of qualification, but the law of contract, upon which we cannot speak dogmatically; but, clearly, in a moral sense, an agreement is binding, whether witnessed or not.

"PERFORATED RUBBER KNEE-CAPS."

To the Editor of THE LANCET.

SIR,—With reference to the above, I observe that your correspondent, Mr. F. D. Huxley, has omitted to give the name of its inventor thirty years ago; neither has he mentioned the names of "practical" men who were compelled, owing to its inutility, to abandon its use in disgust. I recorded personal experience, and should be glad if that gentleman would furnish the same.—I am, Sir, yours faithfully,

Bristol, Sept. 9th, 1884. HUGH THOMAS.

Mr. ——.—There are many good works of the character desired, but we cannot particularise. The one mentioned cannot be recommended.

Mr. A. W. Graham shall receive an answer next week.

IN the list of the Westminster Hospital Lecturers, in our recent Students' Number, the name of Mr. O. Hehner, who conducts the practical chemistry classes, was inadvertently omitted.

Mr. Joseph Morton.—Our correspondent's questions are not clearly put. Question 1 is too hazy to be answered; but we may state that no medical school or society in London "passes" men.—2. No university will accept certificate of success in examinations elsewhere in lieu of its own examinations.—3. No.

Sempronius.—The case is eminently one for friendly settlement.

"CASE IN DENTAL PRACTICE."

To the Editor of THE LANCET.

SIR,—The case quoted by Mr. Percy May in your issue of the 30th ult. concerning the sympathy between ear and teeth is of very great interest, for the relations these parts bear to each other have been very little studied compared with those reflex phenomena which occur in the eye and its structure. In fact, I am not aware of very much explanation having been recorded concerning such cases. For this reflex trouble I have at various times been compelled to advise the removal of teeth for no other reason than that the means adopted for their preservation seemed to increase the evil. One case I have lately had under treatment where the patient, a young man, has a mesial cavity upon the left upper first molar. The tooth is "dead;" the fang cavities have been excavated and filled, but when the cavity is closed the deafness and slight pain in the ear are increased. The tooth is quite free from peridental lesions. Its retention being of great service to the patient, I have loosely filled the fang cavities with cotton-wool and inserted a tube through the filling. I believe there is very little inconvenience for the present.

I am, Sir, yours truly,

W. T. ELLIOTT, L.D.S. Edin. and Dub., F.C.S.

Birmingham, Sept, 8th, 1884.

Richmond.—Yes. Members of other British colleges can be admitted to the examinations of the Royal College of Surgeons of England and the College of Physicians. Certain conditions have to be observed, which will be found stated in our Students' Number or in the Medical Directory.

Volunteer Surgeon.—1 and 2. Longmans and Co.—3. Clowes and Sons.

CHOLERA IN MARSEILLES.

To the Editor of THE LANCET.

SIR,—In a recent issue of your journal I saw an allusion to the fact that there were cases of cholera in Marseilles last autumn. Now that the fact has oozed out there can be no harm in my stating what I know on the subject. Last October I stayed some weeks in Marseilles, attending the hospitals regularly. One day I was taken by a medical friend to see what he called a "clinical curiosity." It was undoubtedly a case of Asiatic cholera, though I was amused to see that the diagnosis put on the board at the head of the bed was "bilious irritation." I believe that an oath was administered by the chaplain to all the medical attendants that they would not divulge what they saw. No such precaution was taken with me, possibly because I was a heretic, and my word was considered as good as my bond—both being equally valueless. I am, Sir, yours faithfully,

ALFRED DRYSDALE, M.B.Lond.,

Mentone, Sept., 1884. Officier de Santé.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Clinical Lecture
ON
PELVIC HÆMATOCELE.

Delivered at St. Mary's Hospital,

BY ALFRED WILTSHIRE, M.D., F.R.C.P.LOND.,
JOINT LECTURER ON OBSTETRIC MEDICINE, AND PHYSICIAN-ACCOUCHEUR FOR OUT-PATIENTS; TREASURER OF THE MEDICAL SOCIETY OF LONDON; FORMERLY MEDICAL INSPECTOR TO HER MAJESTY'S PRIVY COUNCIL.

GENTLEMEN,—Pelvic hæmatocele, the subject of to-day's lecture, comprises the various forms of blood effusion occurring in the pelvic region or pelvi-abdominal cavity. Some of these internal hæmorrhages are accidents of great severity, may even prove rapidly fatal, and are usually more or less grave and painful. For clinical purposes it is desirable to group them under this comprehensive and well-known term, rather than to employ loosely or indifferently those of "retro-uterine," "peri-uterine," or "peri-metric" hæmatocele, or "pelvic hæmatoma," which, if etymologically more accurate as descriptive of varieties, are not altogether free from the fault of postulating hypothetical views, while they divert attention from that clinical concentration and convergence so essential for accurate diagnosis in an affection owning manifold origins. At the bedside it is helpful to have a wide grasp of the possibilities of causation in any malady, and in none more than in pelvic hæmatocele, which may arise in the pregnant or non-pregnant, be of spontaneous or traumatic origin, and may in some cases urgently demand prompt remedial measures. The clinical features of the affection will chiefly occupy us, but some reference to the subjects of etiology and pathology is unavoidable, because upon the correct appreciation thereof depends the accurate interpretation of clinical phenomena as to which there is little disaccord. Moreover, recent experimental and pathological researches, together with some bedside observations of my own, throw fresh light upon problems which to some yet appear obscure, and will, it is hoped, help to solve them. Blood effusions of the kind in question occur mostly during menstrual life, from the fifteenth to the forty-fifth year, and commonly during the prime of that period (twenty to thirty-five), although there are forms to which the epochs of puberty and the change of life are exposed.

As some of you may not yet be clinically familiar with the affection, let me describe to you a typical case, such as is commonly designated the "retro-uterine" form. At or near a catamenial period, which may be checked, retarded, suppressed, or otherwise deranged, and may have been preceded or accompanied by pain, weight, throbbing, tension, and discomfort about the pelvic region or genitals (although premonitory symptoms are not always present), a young woman, married or single, is seized with sudden and severe pain of a stabbing or tearing character in the lower part of the abdomen or groin on either side, and extending into the privates. Faintness ensues, and the sufferer is compelled to lie down. Thereupon speedily follow vomiting, sweating, more or less faintness or even collapse, with a thready pulse. A flow of blood from the genitals often comes on (metrorrhagia) and may be profuse, or there may be none. Frequent efforts at micturition urge the patient, but are followed shortly by retention. Unsatisfactory efforts at defecation may also annoy the sufferer, to whom every movement becomes increasingly distressing. She lies with her knees drawn up, one generally trending over the other—that on the side of the lesion usually—dreading every movement, troubled by thirst, and complaining of bearing down and pressure in the lower part of the body and privates. The countenance becomes anxious, and the extremities and surface generally chilled and clammy, and the whole body may be bedewed with cold sweat. The abdomen is excessively tender, and the parietal muscles tensely contracted. Such an attack may supervene without warning, but more usually patients have been exposed to sudden chill, to mental emotion, moral or physical shock, or have been making some violent effort, all occurring mostly about the time of the menstrual epoch. One of my patients got chilled in a snowstorm while menstruating, and had an intra-peritoneal hæmorrhage; another had a subperitoneal effusion from severe exertion; a third, an effusion between the folds of the left broad ligament from sudden effort in an awkward attitude—catching a young lady who jumped into her arms from a drawing-room stairs. After the acute stage, that of effusion, has subsided, distension of the abdomen supervenes, accompanied in most cases by exquisite sensitiveness. The tongue becomes dry, and later on glazed and striped. Thirst may be insatiable, and vomiting persistent. The aspect of the patient in severe cases is that of profound exhaustion and collapse; and in all of somewhat acute suffering, alarm, and shock. These symptoms, you will observe, resemble those of acute irritant poisoning,[1] and in several instances of sudden death from internal hæmorrhage the suspicion has justly been aroused that the fatal issue was due to poisoning, and has, very properly, led to post-mortem investigation to clear up the doubt.[1] They also simulate those of perforation of gastric ulcers (the ulcer of young women, chlorotic and other, which has a punched-out aspect and tends so readily to perforate, especially about the menstrual periods) or perforation of the intestines, notably in typhoid fever; of strangulation of intestine, hernial or other; of acute retroversion of the gravid uterus, as in a case of my own, and so on. Again, sudden and severe hæmorrhages may occur into the peritoneal cavity from splenic disease, from burst aneurysms or atheromatous arteries,[2] and from hæmatolytic changes, however originating.

So far it may be assumed that observation and inquiry have informed us as to the patients' condition and symptoms, but we are now led to desire such further exact information as physical investigation of the parts or viscera suspected to be implicated will afford. Usually the necessity for pelvic exploration is indicated. In proceeding to consider that subject, let me expressly inculcate the importance of extreme gentleness and delicacy, and enjoin upon you that it is imperative that you explore only with that best of all instruments, the finger—the index finger, and that alone. I am constrained to do this the more emphatically, because it is within my experience that large pelvic effusions, hæmorrhagic and other, have not only remained entirely unrecognised through the exclusive use of specula, but I might go further and mention examples, seen in consultation, where such effusions have altogether escaped recognition, owing to the omission to make any pelvic examination, digital or other. You are aware that I am chary of resorting to internal examinations as a routine practice, but when they are obligatory they should be properly and thoroughly performed. The illumination afforded by pelvic exploration may be great. Take an ordinary case, such as we have already supposed. What shall we find? We should divide the phenomena into those of the *early* stage, where the blood is fluid, and those of the *later* stages, when it has coagulated, omitting for the present changes that ensue when softening from suppuration &c. occurs. If a case be examined shortly after the blood has been effused a *soft* swelling will be found, bulging into the hinder wall of the vagina, and crowding the uterus downwards and forwards against the pubic arch (I am speaking now of the undisputed phenomena of what some call "retro-uterine" hæmatocele).

Should the patient, however, not be examined in the acute stage (and great caution, even reticence, ought then to be exercised) say for two or three days or more, then a similar globular mass will be felt in the posterior vaginal wall behind the womb; but it will be firm and tense, because the effused blood has coagulated, and later on it becomes hard. It is this physical condition, so often met with in a certain class of cases—a mass behind the womb crowding it down against the pubic arch—that has given rise to the name of "retro-uterine" hæmatocele, and has led theorists into disputes and embarrassments as to its seat, whether it is intra- or sub-peritoneal. Is the blood effused freely within the peritoneal cavity? or is it beneath and outside the peritoneum? This is a point upon which I hope to be able to throw some light by showing that usually the blood effusion which crowds the uterus downwards and forwards is beneath the peritoneum, and not inside its sac, as commonly alleged; and that in

[1] See case recorded by Drs. Ogston and MacQuibban, British Medical Journal, April 12th, 1879; also by Tomkins, Ibid., January, 1873. Tardieu relates cases.

[2] Gallard's case, in a woman about fifty-five, quoted by Poncet; De l'Hématocèle Péri-utérine.

Digitized by Google

cases of true intra-peritoneal hæmorrhage, which are apt to be more formidable, the relations of the effused blood to the womb and adjacent viscera are different. By many writers upon this subject it is assumed that the blood is effused into the peritoneal cavity; and upon this hypothesis they are driven to invent an imaginary "limiting membrane," which they allege bounds the superior limit of the mass, and which, it is asserted, is thrown out by the plastic peritonitis excited by the blood, regarded by them as an irritating fluid; and it may be supposed to account for the fact that the uterus is bodily displaced and thrust downwards and forwards, the phrase "crowded down" against or upon the pubic symphysis being a favourite one. As you will presently learn, there are several forms of intra-peritoneal hæmorrhage, but their physical disposition differs from that now under consideration, which is commonly known as "retro-uterine" hæmatocele, and, in accordance with the views advanced by myself and held by others, is beneath that membrane, and external to its sac.

Let us first appeal to certain physical laws—those of hydrostatics—and, so guided, abide by their arbitration. We may then appropriately inquire what light is derived from clinical investigation and experimental research. Observe, first, that if blood be shed freely into a cavity, such as the peritoneal, it obeys the ordinary laws of gravity, and being fluid, behaves as fluids do in accordance with those pertaining to hydrostatics. That is to say, it flows in directions of least resistance, and accommodates itself to bodies of greater specific gravity by adapting itself to them, instead of displacing them; in short, the blood behaves in relation to the pelvic viscera much as would melted fat, a warm solution of gelatine, or newly mixed and fluid plaster-of-Paris, if poured into the pelvic cavity; it moulds and fixes them in their normal positions. Another point to be remembered in this connexion is that patients suffering from these hæmorrhages are usually compelled to lie down speedily, and that obviously tends to favour gravitation of fluid backwards along the posterior part of the abdominal cavity into the most dependent parts. As the intestines often contain gases they may be displaced superiorly to the effused fluid, but only to the length of their mesenteric tether. On the other hand, if blood be shed into yielding tissues, and be bounded by a membrane, such as the peritoneum, or by resilient tissues encapsulating it, such as the broad ligaments with the pelvic platysma enfolded in them and beneath the peritoneum, what then happens? The limiting or bounding membrane or tissue may offer enough resistance to cause some displacement of mobile or partly mobile organs, such as the uterus, which may accordingly be thrust down in the direction of least resistance, downwards and forwards. But it is alleged by some that the peritoneum is so fragile a structure that it must tear easily, and would burst under pressure so slight that it could never withstand the strain of rapid effusion of blood from ruptured vessels. As evidence to the contrary, consider and weigh the following facts. The late Dr. Radford of Manchester published in the Obstetrical Transactions of London, vol. viii., 1867, an essay on "Cases of Laceration of the Uterus." In Case 15 the woman died undelivered just as Dr. Radford arrived, and he found the abdomen to present two tumours, which, on post-mortem examination, proved to be respectively the ruptured uterus on one side and on the other the fœtus (hydrocephalic) lying underneath the peritoneum in an unbroken sac.[3] In Case 17 an enormous blackish-looking tumour, caused by coagulated blood, was found underneath the peritoneum, extending as far as the right psoas muscle, and also distending the broad ligament. In Case 3, from a pound to a pound and a half of blood was found effused behind the peritoneum as high as the mesocolon. "The peritoneal coat was entire." The late Dr. Roberton,[4] among other cases of "laceration of the uterus in complicated labours," mentions one in which the patient died suddenly and unaccountably, and at the post-mortem examination rupture of the uterus was found, and several pounds of blood had escaped and lay under the peritoneum in the left iliac fossa. Dr. Blundell—a great master, whose foresight into abdominal surgery is too little known or recognised in these days—records a case similar to Dr. Radford's of escape of a fœtus from a ruptured womb into a pocket formed by the unlacerated peritoneum. This case occurred in the practice of Mr. Barlow of Blackburn, who deserves undying renown for having boldly forthwith performed abdominal section, whereupon he discovered rupture of the muscular substance without rupture of the uterine peritoneum. The patient recovered rapidly.[5]

Again, a woman admitted into the West Riding Asylum for puerperal mania died suddenly from pelvic hæmatocele, and at the inspection the effused blood was found to rise up to within an inch of the umbilicus, fully occupying the hypogastric and inguinal regions, and to be beneath the peritoneum, that membrane being raised up entire.[6] Mr. Morris[7] mentions a case of rupture of the bladder in a boy upon whom the late Mr. Lyell operated at the Middlesex Hospital by abdominal section, believing that effusion of urine, &c., had occurred into the peritoneal cavity, but neither fluid nor opening could be found. The boy died, and at the post-mortem examination a large quantity of effused blood was found behind and outside the peritoneum, overlying the spine, and in the right iliac fossa. Hæmorrhage had also taken place into the mesentery. "The peritoneum was separated from the anterior abdominal wall just to the right of the symphysis pubis, and was much bruised by the broken pelvis, but not torn anywhere." Mr. Heath[8] records a similar case in a man aged thirty, and Dr. Skerritt has recorded a case of abdominal aneurysm treated by distal compression, in which the aneurysm became diffused; and at the necropsy, seven weeks after compression, rupture was found to have taken place into the retro-peritoneal tissue, forming an enormous false aneurysm composed of soft dark clot and dark fluid blood.

The evidence already adduced is irrefragably conclusive that the peritoneum will bear suddenly produced strain to an enormous extent without rent; but a crucial test *ad hoc* is furnished by a case of Baumgartner's,[9] which he correctly diagnosed as a subperitoneal hæmatoma, and upon which he operated by abdominal section, finding the tumour to be completely covered by peritoneum. Again, a distinguished American physician, Dr. Fordyce Barker, in his admirable work on "Puerperal Diseases" quotes a case from Perret in which a thrombus was found post mortem filling the left lateral half of the pelvic cavity, and the infiltration of blood had extended into the subperitoneal tissue of the abdomen. Dr. Gowers,[10] speaking of splenic leucocythæmia, mentions that subperitoneal hæmorrhage (as well as intra-peritoneal), may occur in that disease. A case of rupture of a fusiform aneurysm of the left common iliac artery, producing an enormous hæmatocele, lying behind the peritoneum and extending from the scrotum below (where it formed a sausage-shaped tumour) up to the level of both kidneys along the back of the abdominal cavity, recorded by Dr. Uthoff of Brighton, is very instructive.[11] Chaussier[12] relates a case of sudden death in a woman pregnant five months where a large effusion of blood was found beneath the peritoneum, extending from the right iliac fossa to the kidney (Poncet). Moreover, the experiments of Tripier, made at the suggestion of Poncet, by injecting liquid coloured with Prussian blue into the uterine annexes, showed that the peritoneum readily stripped up from the subjacent tissues, and that it required a pressure of two atmospheres to rupture the peritoneum, as was determined by the manometer. Baumgartner's analogous experiments yielded similar results.[13] The peritoneum, then, displays marked distensibility under rapid strain, and will peel up with great celerity even under the stress of solid bodies, such as the fœtus, and still more under hydraulic pressure. And then, with reference to the supposed deleteriousness of blood when shed into the peritoneal cavity: that is hypothetical, not to say imaginary. Its innocuity is shown by experiment, as well as proved by clinical experience; neither plastic exudation nor peritonitis is necessarily excited by the effusion of *pure* blood. Again let me appeal to evidence. Of late years quite a number

[3] Dr. Radford's words are: "On opening the abdomen the peritoneum appeared perfectly free from disease; nor was any fluid discovered in its cavity.....The uterus, which was very large, formed one segment of the tumour—viz., the left—and the child's body, covered by the peritoneum, the other. Upon making a very careful examination of these parts, not the smallest laceration was discoverable in any part of the peritoneal covering. An incision was made through this membrane, which exposed the body of the child." A diffused clot was also found under the peritoneum with the child's body.

of experiments have been made upon the tolerance of the peritoneum for blood when poured into it artificially. Valpian and Laborde, Franck, Ponfick, Bizzozero and Golgi, Arloing and Tripier, Livon, Toussaint, Penzoldt and Cordua, have all made corroborative observations. Von Recklinghausen,[14] according to Ziegler,[15] first investigated with success the process of absorption of foreign substances in the abdominal cavity—e.g., milk, tinted liquids, and blood; but recent researches by already named observers are still more conclusive. Poncet,[16] alluding to the experiments of Valpian and Laborde of injecting blood into the peritoneal cavity, says that they throw light upon the little known tolerance of the peritoneum for large quantities of blood and its rapid absorption, and show in a peremptory manner the impossibility of provoking encystment of sanguineous effusions in mammiferæ when the peritoneum is quite healthy. Franck's[17] experiments are also striking and conclusive. He found blood transfused either directly from the carotid of one animal into the peritoneal cavity of another or after defibrination, to be absolutely absorbed within a little over a week, as was shown by post-mortem examination of the animals. Arloing and Tripier's inquiries gave identical results, even when large amounts of blood were used, as much as one-tenth the weight of some of the creatures. The results of M. Livon were similar, the blood was always promptly absorbed, and there was never peritonitis. M. Toussaint, Professor in the Ecole Vétérinaire de Toulouse, made like observations on large as well as small animals (using asses, sheep, &c.) with corroborative results, except in the case of an ewe which, like sheep generally, did not bear operation well. Poncet comments upon the prodigious rapidity with which large quantities of blood were absorbed from the peritoneal cavities of twenty-four animals. Penzoldt and Cordua have studied histologically the characters of the blood, and found defibrinated blood to be most rapidly absorbed. Bizzozero and Golgi[18] made observations on the influence of peritoneal transfusion of blood on the globular richness of the blood in the circulating apparatus, and found that it was rapidly enriched. Ziegler[19] remarks that the rapid absorption of blood from the peritoneum has a practical value, and suggests the possibility of similar successful transfusion in the human subject, and I think I have somewhere seen accounts of such a case, but I cannot find the reference.

It should be recognised that there are two distinct classes of pelvic or pelvi-abdominal blood effusion, and that either may arise from several, and in some cases identical lesions. First, there is that which is always external to the peritoneum—e.g., as between the broad ligaments, or rectum, bladder, and uterus, and beneath the peritoneum of the pelvic and pelvi-abdominal regions, where fused with the pelvic platysma (Rouget's muscle), arising from burst veins, &c. Secondly, that which is within the sac of the peritoneum, a large and important class, comprising rupture of ectopic gestation sacs, burst varicose or other veins of the utero-ovarian plexus, whether in the pregnant or non-pregnant (illustrations were given), from burst uterus (one horned or other); from hæmato-salpinx or burst Fallopian tube, or ovary; from aneurysm, ruptured atheromatous artery within the abdomen, burst bladder, and various traumatisms; from bleeding from the Graafian follicle in hæmatolytic conditions; from regurgitation through the Fallopian tubes, burst spleen, liver, or kidney; from exhalation of blood from the peritoneum, without recognisable lesion, as seen in purpuric states, acute specific diseases (e.g., small-pox), and after phosphorus poisoning; in short, in hæmatolytic conditions, however produced. These large, profuse, and sudden intra-peritoneal hæmorrhages have been well named cataclysmic by Dr. Barnes, and may be of deadly import.

Let us now learn what happens when blood is shed freely into the peritoneal cavity. If pure blood only be shed, the irritation from its mere presence *qua* blood is not severe, although death may speedily occur from collapse, and be preceded by convulsions. In conformity with the laws governing fluids, it does not collect only in the pelvis, but also flows backwards along the hinder part of the belly cavity, this reflux being favoured by the lying down of the patient. Nor, when pure, does it excite peritonitis, and thus provide an encysting capsule. That hypothesis is invoked by those whose minds are dominated by preconceptions as to the acrid or irritating action of blood upon the peritoneum. It is beyond question that patients suffer severely in various ways, from loss of blood, and so on; and probably in some cases the material effused is not pure blood, but either blood whose vitality is damaged or impaired (perhaps putrid), or matters from extra-uterine gestation sacs and the like, as foul blood from the tubes, ovaries, tumours, ruptured bladder growths, and so on. Hæmorrhages from malignant intra-abdominal growths are hardly within our present purview.

When patients do not sink under acute loss of blood internally, the physical condition found per pelvem in most cases (i.e., where pure blood alone is effused into the peritoneum) is that of fixity of the pelvic viscera in their normal relations and positions. This I have repeatedly verified in cases of intra-peritoneal hæmorrhage. When the blood is damaged, clotting may be absent or long deferred if the patient survive.

Let us now turn from the topical to the general or systemic symptoms of pelvic hæmatocele. As most of the early symptoms have already been mentioned, a brief recapitulation will suffice. The one-sided pain of a sharp character low down in the pelvis and down the genitals and thighs; the breathlessness, collapse, and, in very severe cases, convulsions from loss of blood; the cold sweats, the thirst, vomiting, and low temperature of the body; the attitude, the legs so significantly drawn up, the one on the side of the lesion usually the more so; the thready, flickering pulse; the dysuria and bearing down in the privates—all tell their tale plainly enough. Uterine epistaxis, metrorrhagia, or menorrhagia are frequent, almost constant, accompaniments.

Later on there will be feverishness when reaction supervenes. The tongue becomes dry, glazed, and striped, ribbon-like; it is the "pelvic tongue." The pulse becomes quick. The abdomen enlarges either from distension or from encroachment of the tumour upwards, as in many of the sub-peritoneal forms—the "hæmatomata," or "thrombi," as some prefer to designate them. Here I wish to mention another special symptom observable in hæmatoceles, the presence of which is constant, and of which I have satisfied myself by observation of many cases during the past fourteen years. It is that of an icteric or jaundiced hue which overspreads the surface after a few days. I was first made acquainted with this about 1870 in the person of a patient at the West London Hospital, who came under my care, in the first place as an out-patient, when I found a huge pelvic hæmatocele in the recent and fluid state. I at once admitted her into hospital, and in a few days the mass became firm and solid. It rose as high as the umbilicus, and almost blockaded the pelvis. I diagnosed a subperitoneal effusion, and watched the case carefully. After about a fortnight or more she became so distinctly yellow that a colleague remarked that she was a good case of jaundice. He was not a little surprised when I informed him that observation of her motions showed no want of bile, and that chemical tests of her urine yielded no evidence of presence of bile—that, in short, the case was not of biliary origin, but one of hæmatic jaundice, due to absorption of the colouring matter of the blood from the large effusion. Since that time I have been on the alert to observe all cases of hæmatocele whether occurring in hospital or consultation practice, and with invariably corroborative results. Of course the amount of icteric hue will depend partly upon the amount of effusion and partly upon its seat. Fortunately for the corroboration of this clinical manifestation a case of traumatic scrotal hæmatocele was admitted into the West London Hospital a few months after the observation of my pelvic hæmatocele case. It occurred in the person of a young man aged about twenty-four years, and was of considerable volume. Being present on his admission, and finding there was no wound, I begged my surgical colleague, under whose care he fell, to do me the favour of refraining from incising the scrotum to let out the blood-clots, explaining to him my object, and predicting that in a few weeks the patient would become icteric. Accordingly only spirit lotion was applied, and in due course the young man became quite yellow as the effused blood was absorbed. There was, moreover, no sign of biliary implication. Dr. Ginders of Normanton, surgeon to the railway works there, who has seen many cases of traumatic scrotal hæmatocele, kindly informed me, in reply to inquiries upon the point, that when he refrained from opening the scrotum the men not only became yellow, but some were actually green, an observation which tallies with the spontaneous remark

of a lady who suffered from a severe pelvic hæmatocele, that she became "sage-green." This condition of hæmatic jaundice agrees with the "Ictère Hématique Traumatique" of Poncet, and has analogies with the "Ictère Hémaphéique" of Gubler; it is due to rapid absorption of the colouring matter of the blood—the hæmoglobin. It is also akin to the icterics witnessed in other hæmatolytic affections, as in paroxysmal hæmoglobinuria (or, as I have formerly suggested, paroxysmal hæmatolysis or hæmatolysuria), chlorosis, icterus neonatorum, and blood poisons (animal—e.g., snake and other). The urine shows the source of the pigment to be the blood by the presence of colouring matters in excess—urohæmatin, &c.; and chemical and spectroscopic evidence is corroborative. The observations of Ponfick, MacMunn, Poncet, and others support this view. The clinical value of this symptom of hæmatic icterus has to myself been very great. It was well illustrated in a case seen by me with Dr. Lacey, also in one with Dr. Walker and another with Mr. Moon, and was helpful recently in one seen with the Messrs. Shillitoe, senior and junior, at Hitchin, besides in many others. Very notably, also, in a case recently in St. Mary's Hospital, where internal hæmorrhage to a considerable amount occurred from the stump of an old ovarian pedicle, after exertion, in a woman on whom I performed ovariotomy several years ago. This patient was so sallow that the general impression was that she had cancer, but her recovery verified the diagnosis of hæmatic jaundice. The yellowness beguiles many into the belief that "liver disorder" is present; and I have known horse exercise and blue-pill ordered for a lady whose pelvis was blocked with effusion. I mentioned that puberty and the menopause were not free from pelvic hæmatoceles. I have seen examples of both in consultation: one at the change of life notably with Mr. Moon of Norwood, and others at various times with other gentlemen.

Among the causes of one form of pelvic hæmatocele I have already mentioned bursting of extra-uterine pregnancy sacs, especially in the tubal variety. This cause is by some alleged to be the only one in pelvic hæmatoceles, but that inference or assertion is erroneous if imposed as absolute, although no doubt a large proportion of cataclysmic hæmatoceles own this origin. The class is unquestionably a large and important one, and I have myself seen several cases, some in consultation with Dr. Alderson, Mr. Mason, Mr. Duke, Mr. Senior, Mr. Parrott, and other gentlemen; others in public and private work. I show you specimens of ruptured tubal sacs and of fœtal relics from a case seen with Dr. Alderson. In these cases, when an accurate diagnosis is attainable, prompt operative measures may be required to save the patient, although they do not all die, for among the cases above alluded to only one proved fatal (the one seen with Mr. Mason), the patient succumbing a few hours after I saw her, without any operation being practised.

Among the causes of pelvic hæmatocele must be mentioned bursting of a vein in the utero-ovarian (or pampiniform) plexus, whether varicose or no. It is probable that this occurs in many of the subperitoneal cases, but it may also give rise to intra-peritoneal bleeding. The stress thrown upon the vascular apparatus of the pelvis during the menstrual nisus is great, and under abnormal conditions, such as chills, suppression of menses, emotions (erotic and other), and so on, weakened vessels may give way, as has been verified by many post-mortem examinations. An internal hæmatoma or thrombus thus produced has analogies with those occurring in the labia externally from various causes; and, like the latter, are no doubt in some cases vicarious. Cases illustrative are recorded by Jacquemier, Puech, Lissner, and Ledouple; and Billroth alludes to episio-hæmatomata. The venous plexus, internal and external, are *erectile* structures.

Rupture of Graafian vesicles is attended by a small hæmorrhage into the follicle normally, but under hæmatolytic conditions this slight "menstruation of the follicle" as it is called, may become excessive, and produce great internal loss. The specimens I show you illustrate this possibility. Certain writers on pelvic hæmatoceles allege that they chiefly arise from rupture of neo-membranes produced by pachyperitonitis. Bernutz advocates this view, which undoubtedly is a restricted one. This preliminary pachyperitonitis is sometimes invoked and formulated to help out the hypothesis as to encapsulation. It doubtless does occasionally happen that neo-membranes form, and they may yield blood on being torn; but it is doubtful whether they are at all a frequent source of hæmatoceles. Virchow first called attention to the formation of neo-membranes and possibility of some hæmorrhage from laceration of young vessels, but large effusions from such sources are rare. Traumatic rupture of ovarian cysts may cause serious trouble and internal hæmorrhage, as in a case seen by myself in consultation with Dr. Oldham, Dr. Swann of Dublin, and Mr. Skelding. The patient recovered, and remains well. Rupture of the uterus, in the lower segment particularly, is an occasional cause, and was present in a remarkable case I saw in consultation with Dr. Owen Roberts, where a large effusion of blood was produced within the folds of the left broad ligament from spontaneous rupture of the lower segment of the womb during labour a week after the accident of slipping on the patient's doorstep. Reflux of menstrual blood through the Fallopian tubes is asserted by some writers to be a frequent cause of pelvic hæmatocele. Probably this is extremely rare, and the evidence of its occurrence is by no means conclusive. Its possibility must be admitted, but it is remarkable how rarely anything of the kind occurs in imperforate hymen and other atresial conditions preventing the escape of menstrual fluid.

A very serious condition rarely met with is that in which an enormous quantity of blood is found post mortem in the peritoneal cavity, without discoverable source, and apparently from exhalation. I have seen one such case (I think with Mr. Mason), where we could find no lesion to account for the bleeding. I do not say there was none; but we failed to find any. In some of these cases the blood may resemble that of purpura—in short, may be a form of hæmatolysis, and in such cases it never clots. A case of peritoneal exhalation is actually recorded by Mollière in the subject of hæmophilia. My own clinical observation leads me to the conviction that there may also be a form of pelvic hæmatocele due to lesions in the nervous centres. Drapier's case, mentioned in his thesis "L'Hématocele Rétro-utérine consécutive à la Pelvi-péritonite" (p. 16), is an illustration.[20] I have met with a somewhat analogous case, which was seen with me by Dr. Ferrier. The researches of Nothnagel, Brown-Séquard, Vulpian, Jehn, and Charcot respecting hæmorrhages into the lungs and other viscera consecutive to cerebral lesions are interesting and suggestive in this connexion; while Andral cites a case from Serres of hæmorrhage from the sexual organs of an aged woman from cerebral hæmorrhage, and of priapism in men from like lesions, showing influence over the sexual zone. Dr. Savage's case (Bethlem) of "melancholia passing into partial dementia, following childbirth, which recovered suddenly and permanently after formation of retro-uterine hæmatocele," is suggestive, as also is the influence of emotion and shock.

Probably lesions of the spinal and sympathetic systems may be operative, especially when the latter implicates the vaso-motor system, which it so largely influences. Vulpian's observations in his "Leçons sur l'Appareil Vaso-moteur" are suggestive; and so also are those of Marotte,[21] who cites the influence of lumbo-sacral neuralgias on the production of hæmatoceles; and Cohen's on congestions seen in ileo-lumbar forms of neuralgia which provoke congestions of the womb and its annexes. It should not be forgotten in this connexion that embolism of the mesenteric arteries is attended by hæmorrhage from the bowel, the mechanism whereof has been shown by Vulpian.[22] Considered in their entirety, then, the various hæmorrhages which may occur in connexion with pelvic and abdominal lesions, and which for clinical purposes may be grouped under the comprehensive term pelvic hæmatocele, form an important class, some acquaintance with which is demanded from the diagnostician who desires not to be led astray by preconceived notions which would limit and hamper his grasp of the subject.

As to the treatment of pelvic hæmatoceles, the cardinal injunction in most cases is absolute rest and opium. The value of opium is here transcendent. It tranquillises, relieves pain, and enables the exhausted and collapsed patient better to bear the blood loss, while it compels repose, both mental and bodily. But to procure these desirable ends it must be given in full doses, and be repeated as may be necessary. The best method is to give it in one-grain

[20] Drapier gives it under the following heading:—"Hémorrhagie cérébrale; coma; mort. Autopsie: Vaste foyer hémorrhagique dans le lobe moyen de l'hémisphere droit; épanchement dans le ventricule latérale correspondant; anevrysme miliares; hématomes rétro-utérines; hématomes ovariens.

Digitized by Google

doses of the solid opium, either in pill or powder. Next to solid opium, Battley's sedative solution of opium is good; but morphia is much less useful in these hæmorrhages, especially in the cataclysmic forms. Ice and brandy, champagne, or other suitable stimulants may be requisite; and, above all, Valentine's meat-juice is most valuable. Peptonised meats and other foods (Benger's, Darby's, and others) may be useful adjuncts. In certain cases the hypodermic injection of ergotinine of Tanret (Paris) may be helpful, and tincture of hamamelis may help in certain forms. The bladder should be relieved by catheterism with antiseptic precautions, as may be required. The use of astringents, such as gallic and other acids, is not great in these accidents, nor can I recommend the use of heavy bags of ice to the abdomen. But besides medical treatment, certain grave surgical questions arise in some cases, and demand urgent solution: for example, in cases where there are reasonable grounds for suspecting the source of internal hæmorrhage to be a ruptured tubal or other pregnancy, and in similar accidents, such as bursting of a vein in the pampiniform plexus or elsewhere, where the diagnosis is sufficiently clear; in short, in those cataclysmic intra-peritoneal bleedings where rapid dissolution is threatened prompt operation may not only be justified, but become imperative to rescue the patient from impending death. It must not be forgotten, however, that even in ruptured ectopic gestations many patients recover without operation, as has happened several times within my own experience. The difficulty of accurate diagnosis is no doubt sometimes great, but not always; and when the well-balanced judgment arrives at reasonable grounds for belief that hæmorrhage threatening to be rapidly fatal is going on unchecked from a controllable vascular lesion, then a bold, but not rash, interference is justifiable, and in these days of heroic abdominal surgery laparotomy should be done without delay.

During the later stages of pelvic hæmatoceles watchful supervision of the patient is necessary. The bladder should be carefully attended to with scrupulous cleanliness and great gentleness. Bedsores should be prevented if possible. The bowels as a rule should be seldom opened. The mouth often becomes sore from the glazy and raw condition of the tongue and lips, therefore all food should be bland. Sedative mouth-washes give much relief (borax, myrrh, wine of opium, mucilages, and orange-flower or rose-water). The better patients are fed and cared for the sooner does the effusion disappear according to my experience. Care should be taken to guard against relapses or exacerbations, which are apt to occur about the time of the next catamenial period. I have been able occasionally to predict a fresh effusion at these epochs; and when such happens, it is followed by fresh manifestations of hæmatic jaundice. There is periodicity about these forms of hæmorrhage, and the explanation of effusions occurring at the inter-menstrual or fortnightly periods is that it is part of a minor nisus that happens then. The condition of the vascular system will warn the physician, and the sphygmograph or finger may indicate increased arterial tension, while the eye can see the venous turgescence. Undue vascular excitement may be reduced by aconite, amyl-nitrite, nitro-glycerine, the bromides, &c. The pelvic viscera may be quieted by actæa racemosa, monobromide of camphor, Indian hemp, opium, gelsemine, and so on, given internally, and by vaginal pessaries of iodoform, coniæ, morphia, atropia, &c., or by rectal suppositories. An atmosphere of turpentine about the sick chamber is good, both for styptic and purifying influences. With reference to the puncture of hæmatoceles, I should, as a rule, deprecate opening, and would counsel caution in resorting to any operative measures. Should relief become necessary in the later stages from suspicion of suppuration or decomposition of blood, or from clear evidence of intolerable or dangerous tension, then aspirate by the vagina and not by the rectum; but operation is generally undesirable, and should be carefully resorted to. During convalescence sea air and water will be found beneficial, and where absorption is tardy poultices of scalded seaweed and brine baths are essential. The air of Harrogate is also good as promoting metabolism, and occasionally iodine waters, notably those of Woodhall Spa, Horncastle, are good.

In conclusion, let me ask you to remember the two clinical points I would urge: the behaviour of effused blood according to its position, intra- or extra-peritoneally, and the symptom of hæmatic jaundice, slight or well-marked, from absorption of the colouring matter of the blood, and I believe you will find them helpful in your bedside practice.

LONDON TEACHERS OF ANATOMY: A RETROSPECT.

BY CHARLES HAWKINS, F.R.C.S.

IN the obituary of Mr. Cæsar Hawkins, published in THE LANCET of July 26th, it is stated that "he was the last member of the great Hunterian school founded by William Hunter in Great Windmill-street." Perhaps a few notes relative to those who taught in that school, as well as to some of the early days of anatomical teaching, will be interesting.

William Hunter may be said to have been the founder of anatomical schools in London. The first Act of Parliament respecting the practice of anatomy was passed in 1540, in which it was recited "that the masters and governors of the Mystery and Commonalty of Barbers and Surgeons in London should take the bodies of four persons condemned and adjudged and put to death; and make incision of the said dead bodies, or otherwise to order the same after their said discretion and pleasure for the further and better knowledge, instruction, insight, and learning in the said science or faculty of surgery." This Act was repealed by the Anatomy Act of 1832. The "Readers in Anatomy" at Barber-Surgeons' Hall were at first supplied by the College of Physicians. Caius, the pupil of Vesalius, is said to have been the first. In 1566 the United Company of Barbers and Surgeons passed a bye-law that no private anatomy be dissected out of the Hall under a fine of £10. In 1590 Dr. (afterwards Sir William) Paddy was appointed Reader; in 1609, Dr. Gwynne; in 1649, Dr. (afterwards Sir Charles) Scarborough; in 1708, Dr. Mead. In 1629 the Company ordered "that the ancientest master should read the lectures, and so after every surgeon in his antiquity and degree in the Company." In 1046 Edward Arris paid £200 for the Company to establish an annual public anatomy; in 1698 it was ordered "that there be an anatomy lecture called Gale's Anatomy."

In the beginning of 1700 private lecturing commenced. Cheselden, then twenty-two years old, lectured in 1711; Frank Nicholls in 1728; Nourse of St. Bartholomew's Hospital lectured at London House in Aldersgate-street in 1730; Bromfield of St. George's Hospital was elected anatomical demonstrator at Barber-Surgeons' Hall in 1744, Cheselden being one of the wardens. In 1746 William Hunter, a pupil of St. George's Hospital and a Member of the Corporation of Surgeons in 1747, succeeding Sharp, his teacher, commenced a course of lectures to a "Society of Navy Surgeons" in Covent-garden in the evening; but Garrick, at that time appearing at another theatre, was a rival Hunter could not compete with, and finding his theatre deserted was compelled to lecture in the afternoon. At this period the courses of lectures were not extended over a length of time. Bromfield comprised anatomy and surgery in thirty-six lectures; Nicholls professed to teach anatomy, physiology, and midwifery in thirty-nine; Nourse, the whole of anatomy in twenty-three. Hunter's first lecture produced about seventy guineas, which he carried home in a bag, remarking that it was a larger sum than ever he had been master of; this was the nucleus of the fortune he subsequently acquired which enabled him to spend £100,000 on that magnificent collection now at Glasgow, although it is recorded that he was obliged to postpone the commencement of his third year's lectures on account of not having the wherewithal for necessary advertisements. He continued to teach in, I conclude, the house of his master, Douglas, where he lived until he removed, about 1750, to Jermyn-street. In 1755 he admitted his brother as a partner in his lectures; this arrangement ceased upon John Hunter going abroad in 1761, and was never renewed, so that he was not a member of the Great Windmill-street School. At this time he was joined by Hewson; they parted company in 1770, upon a personal misunderstanding, he building a theatre in Crown-street, where he lectured, but died after a short illness in 1774.

In 1765 William Hunter applied to the Government to have granted him a piece of ground, part of that on which the National Gallery now stands, that he might erect a building fit for the purpose of a School of Anatomy, and supplied a plan "for a museum in London, for the improve-

Digitized by Google

ment of anatomy, surgery, and physic." Upon this being declined, he commenced building the Hunterian School in Great Windmill-street, comprising a mansion, museum, theatre, and anatomical department. He removed into the house in 1768, resigning his house in Jermyn-street to John Hunter, where he lived until he removed to Leicester-square in 1783. Most accounts give the date as 1770; but the lists of the College of Physicians show that his address in 1767 was Jermyn-street, and Great Windmill-street in 1768. In 1771 he was joined by Cruickshank, who lectured until the day of his death in 1800. On March 15th, 1783, he commenced a course of lectures on Surgery, but was removed from the theatre in an insensible state, to die on the 30th of the same month. In 1784 his nephew, Mathew Baillie, joined Cruickshank in lecturing, and continued to do so until 1799. In 1785 James Wilson, a pupil of William and John Hunter, commenced as demonstrator to Baillie, and when he quitted the school he became joint lecturer with Cruickshank, and continued teaching until his death in 1821, which was as sudden as his predecessors', Hunter and Cruickshank. In 1807 Wilson purchased the freehold of the premises in Great Windmill-street, and inhabited the house, as Hunter and Baillie had previously done. He subsequently sold the property, reserving the school part of the premises on a lease. When Honoratus Leigh Thomas began to teach in Great Windmill-street I am not certain. Brodie found him there in 1802, and says in his Autobiography:—"He delivered only a few anatomical lectures. He was not fond of his vocation as a teacher, and was led to play truant a good deal." In 1805 he resigned, when Brodie commenced to teach in Great Windmill-street, which he continued to do until 1812, when Wilson proposed that he should take the school off his hands. This offer he declined, not possessing the funds required for the transfer. Thus ended his career as a teacher of anatomy. In 1808 he had commenced lecturing on surgery, and on parting from Wilson he took a house in Great Windmill-street, where he built a theatre and museum; these lectures he continued until 1830, when the school removed to St. George's Hospital. On Brodie's retirement from the school in 1812 Charles Bell joined Wilson. He had commenced lecturing in London in 1806. In one of those most interesting letters published in 1870—which anybody wishing to have an insight of medical society at the commencement of the present century should read—he says: "I resolved to remain in London, and took a large ruinous house in Leicester-square, previously inhabited by Speaker Onslow. When I got into the house, the first night I slept in it, I had put out the candle, and leaping into bed, the floor gave way under my foot, and I found that I had displaced the board. On examining this in the morning I discovered a tube under the loose board; it was the house where the 'invisible girl' exhibited!" In a letter, October 7th, 1812, he says, "I gave my first lecture yesterday in Great Windmill-street. I gave an hour and a half to a full class; there were from eighty to a hundred, not gathered for the occasion, but pupils of the class." His brother-in-law, John Shaw, assisted him in his lectures and dissections until his death, which took place in 1827. In one of his letters at this time he says: "I have lost my dear and best friend, John Shaw. There is such a blank, I have not an idea left." In 1828 Bell opened the Medical School at University College, then called London University. On the institution of this school, Sir Benjamin Brodie was solicited by the Council to undertake the duties of either professor of anatomy or surgery, with any assistants he might wish to have. In 1826 Herbert Mayo and Cæsar Hawkins purchased Bell's interest in the school, he continuing to lecture in the session 1826-27, and they carried on the school until October, 1830, when Cæsar Hawkins left for the opening of St. George's Hospital School, and Mayo in 1831 for King's College. In the winter session of 1830-31 Mr. Thomas Tatum gave the anatomical demonstrations. Subsequently, Mr. Gregory Smith and Mr. Bushell delivered lectures. Mr. Smith afterwards removed to the school in Little Windmill-street, where Mr. Prescott Hewett joined him in October, 1836, as demonstrator previous to his being house-surgeon at St. George's Hospital in 1838.

I venture to add some criticisms on those I have mentioned as teachers. Baillie said of William Hunter: "He excelled very much any lecturer whom I have ever heard in the clearness of his arrangements, the aptness of his illustrations, and the elegance of his diction; he was perhaps the best teacher of anatomy that ever lived." Brodie, born the year William Hunter died, says in his Hunterian Oration, delivered in 1837: "Hewson partook in no small degree of his master's zeal and industry, and his works show how much may be accomplished by means of these qualities when infused into a mind of moderate dimensions. Cruickshank, over-sensitive and hypochondriacal as he was from disease, was much superior to Hewson; his physiological papers in the Philosophical Transactions and his treatise on the absorbent vessels exhibit a combination of genius and learning, and justify us in assigning him a very high place in the scale of men of genius." And in his Autobiography he says of Wilson: "He had a most profound knowledge of his subject, and his demonstrations were very far superior to those of any other anatomist of that day"—and I may, I believe, add to those of any one since.

In writing this sketch of a school I have been struck with an interesting intellectual lineage. A sister of William and John Hunter was the mother of Mathew Baillie and his gifted sister, the well-known authoress. Baillie married the daughter of the celebrated Dr. Denman, the father of the first Lord Denman, distinguished as a great lawyer. Dr. Denman married the aunt of Sir Benjamin Brodie. The second Sir B. Brodie, by his writings in science, gave evidence of his claim to be ranked as a distinguished professor of chemistry. Dr. Baillie's son, Mr. William Hunter Baillie, is one of the present trustees of the Hunterian Museum at the College of Surgeons.

Savile-row.

OSTEOTOMY FOR GENU VALGUM.[1]

By WILLIAM MACEWEN, M.D. GLASG.,
SURGEON AND LECTURER ON SURGERY, ROYAL INFIRMARY, AND SURGEON TO THE CHILDREN'S HOSPITAL, GLASGOW.

OSTEOTOMY, as a means of cure of genu valgum, has been before the profession now for about seven years, and during the last three or four it has been very extensively adopted by surgeons over the civilised world. The present is therefore a fitting time for eliciting an expression of opinion concerning it. From the manner in which the subject has been framed, I apprehend that we are not to discuss the various methods of treatment of genu valgum, but that we are to confine our attention to osteotomy for that disease. In the limited time at our disposal it is necessary that we confine our attention to a few points only. I have considered that the two following could be discussed with advantage:—

1. The various methods of performing osteotomy for genu valgum and their comparative qualities.
2. The results of these operations.

As to the first point, we have to consider whether the intra- or the extra-articular method ought to be adopted, whether the femur or the tibia ought to be selected for the operation. It is presumed that all of the members are sufficiently acquainted with the descriptions of Ogston's (and its various modifications), Billroth's, Schede's, Chiene's, and Macewen's operations to render it unnecessary to say anything on these points. It would be out of place in me to say anything as to the comparative qualities of these operations, considering my close connexion with the last one mentioned. I have the more reason for doing this as I know that the gentlemen whose names are most closely identified with the various operations are present. Regarding the second question, I have gathered statistics which will help the members in forming a conclusion on the subject.

A schedule was drawn out, asking for statistics concerning osteotomy for genu valgum, and a copy was addressed to every hospital surgeon in Britain. Replies have been received from about forty-five surgeons, but only thirty-seven of these have been able to answer the questions sufficiently fully to permit of them being of value. The statistics received have been formed into a table, which is here presented to the members of the International Medical Congress. The table must not be understood to be a complete one, inasmuch as many surgeons have not been able to reply, which it is hoped they will yet do. With regard to continental and American surgeons, I trust to be able to arrange a similar scheme by which they may be inclined to favour

[1] A paper read as introduction to a discussion on Osteotomy for Genu Valgum, International Medical Congress, Copenhagen, 1884.

Digitized by Google

me with their results, so as to obtain as wide a basis for deduction as possible. The table as it stands is made up of statistics furnished by thirty-seven surgeons. They have operated on 1118 limbs. In some instances only have the number of patients, as well as the number of limbs, been given. The ages of the persons operated on extend from three to thirty-nine years. The operations which have been chosen by those thirty-seven surgeons are as follows:—

Three surgeons have performed Ogston's exclusively; eight surgeons have performed sometimes Ogston's, sometimes another operation. Eleven surgeons in all have used Ogston's operation; these eleven surgeons have operated on 525 limbs, one gentleman alone having performed 370.

Chiene's method has been used exclusively by one surgeon, Professor Chiene himself. One surgeon has twice performed Chiene's along with another method of osteotomy. Two surgeons have thus performed Chiene's operation; these two have performed operations on fifteen limbs.

No one has operated by Schede's method exclusively. Two surgeons have performed occasionally Schede's operation; these two surgeons have operated by Schede's method on five limbs.

Twenty-two surgeons have used Macewen's method exclusively. Eleven surgeons have used Macewen's method occasionally, giving a total of thirty-three surgeons out of thirty-seven who have used Macewen's method; these thirty-three surgeons have operated on 560 limbs.

The next question referred to accidents during the operations. Hæmorrhage is mentioned in two of Macewen's, in thirteen of Ogston's, and in one of Chiene's. The knife was broken off in the joint in one of Ogston's. As to the conduct of the operation, thirty-four of the surgeons used spray and other Listerian precautions, while three conducted the operation by the open method.

The progress under treatment shows that thirty-two cases of Macewen's operation afterwards suppurated, eight cases of Ogston's, and one of Chiene's—that is, forty-one in all have suppurated. Of fatalities there are five cases in all after Macewen's operation. One from blood poisoning (this though stated to be Macewen's operation was not in reality such), one from septicæmia, one from phthisis, one from congestion of the lungs, and one from scarlet fever. In the last three the operation is not credited with the result. Of recoveries there have been 1113 out of 1118 limbs. The results as to utility of limbs show that anchylosis has taken place in two of Macewen's operations, in four of Ogston's (one with dislocation of the patella), and in one of Chiene's. In two of Ogston's bow legs resulted after the operation. All the others were good.

As to relapses after the operation, Macewen's operation has been followed by four such, mostly occurring in young children (one stated to have recovered after using supports for a short time is not counted). One gentleman who has performed both Ogston's and Macewen's has had three returns to the deformed condition. In one of Chiene's there was a return, but in this case the patient had led an irregular life. In one of Chiene's, amputation had to be resorted to about a year after he had performed his operation. The amputation was rendered necessary by the onset of gelatinous degeneration of the synovial membrane. The average duration of treatment has been from one to three months. Mr. Chiene, however, states that he only keeps his patients in the wards for twenty-two days after the operation. Regarding the answer to this question, it is evident that considerable difference of opinion exists as to the meaning of it. Some give the number of days necessary for the patient to remain in bed, while others give the time necessary to fit him for resuming his work.

Statistics of my own Operations.—Up to July 31st of this year I have operated on 804 limbs belonging to 490 patients, and on these have performed 820 osteotomies for genu valgum. The ages have been from seven to forty-six years; the great majority being adolescents. The operation was never undertaken unless after the stage of ramollissement had passed. The supra-condyloid method has been performed alone in 810 instances; in five it was assisted by Schede's operation on the tibia, while in the remaining five modifications of the supra-condyloid method were performed (in the earlier days of my experience). When operating for genu valgum by the supra-condyloid method, the anatomical lines formerly laid down by me have been strictly adhered to, and I have never had occasion to apply a ligature. As a rule there have only been a few drops of blood, sufficient to leave a slight stain on the sponge. The operations have been conducted throughout under the spray, and with strict Listerian precautions.

In eight cases suppuration took place; in six the cause was pressure or some extra force applied, under accidental circumstances. In one it was due to diphtheria of wounds. During the last three years no suppuration ensued after any osteotomy for genu valgum.

Mortality after Supra condyloid Method.—Since the last report two patients, who had been operated on for genu valgum, have died. Both were weak adults with marked deformities. The first was aged twenty-four years. He was operated on for aggravated bow-leg and knock-knee. He had a history of hæmoptysis, and the apices of his lungs were dull. From what could be ascertained at the time, as well as from the information supplied by his medical attendant, there were no recent advances of the disease. It was evident that the degree of deformity of his limbs was such that his health was necessarily kept below par by want of exercise. Unless the condition of his limbs was rectified, it was doubtful whether his strength would improve, and it was certain that he could not lead a useful life. So keenly did he feel this that he urged the operation. For the first week after the operation he progressed well. There was no untoward symptom. At the end of that period the temperature began to show a rise in the afternoons. He had a slight cough, accompanied by a considerable degree of aphonia. He had profuse night sweats. The upper portions of his lungs were affected with coarse crepitant rales, except at the very apices, which were dull. On the ninth day after operation there was a thin liquid discharge of pus found in the wound on the bow leg, which continued. His condition gradually became worse; hæmoptysis came on in a severe form, and he died one month and two days after the operation. The post-mortem showed that the wound on the bow-leg was not healed. The genu valgum wound was healed, though the union of the bone was weak. The upper lobes of the lung were filled with tubercle; at the apices it was of old standing, having undergone degeneration, while lower there was a fresh deposition of miliary tubercle, with ulceration at parts. The bases were free.

The other case was also that of a weak adult, who had marked genu valgum, preventing him from working or from walking other than very short distances. On the twelfth day after the operation his temperature rose, and on the thirteenth it had reached 102·6°. His limbs were examined, the wounds found healthy, and there was nothing in their appearance to account for the increased temperature. On the fourteenth day it was 103°, and still the cause was not discovered. On the fifteenth a stain was seen on the sheet, and on examination it was found to have proceeded from a sore over the sacrum, of which he had never complained, and stated that he had not been aware of its presence. This sore at first seemed superficial and was covered with a greyish membrane, which on removal left rather a deep raw inflamed surface. Next day it was seen that the area of the sore had considerably increased, and that another layer of greyish membrane implicating the tissues had formed over its surface. The temperature was now 104° to 105°. On the seventeenth day he complained for the first time of pain in his limbs. The wounds were therefore again inspected, when both were seen to be covered with a greyish false membrane, similar to that which covered the bed-sore. There was at this time very little discharge, and the little that was present was serous. This membrane was deeply seated, involving the superficial layers, and penetrated into the interior of the wounds. It was removed; but at the next dressing the sores had greatly enlarged, and were again covered by thick false membrane, while the discharge of thin matter—pus and bloody serum—was profuse. It was evident that we had to deal with a case of diphtheria of wounds, showing itself, first, in the sore over the sacrum, rapidly affecting the constitution, and through it the wounds on the limbs. Notwithstanding vigorous measures at destruction of the membrane by external means and internal remedies the sores increased with great rapidity. The greyish membrane on removal exposed a bleeding, raw, inflamed surface. The mucous membranes later became involved, and at the same time he had profuse diarrhœa, with shreds of membrane in the stools. The patient died thirty-two days after the operation and twenty after the onset of the illness. The post-mortem, besides showing the diphtheritic membrane on the sores, revealed its presence in the alimentary canal, the fauces, œsophagus, and rectum. The intestines were much congested. The liver was five pounds

and a half in weight and was two-thirds fatty. The ward drainage was at this time in a bad condition. Several patients who had been operated on for other affections were attacked. Enteric fever became epidemic, nurses and patients being struck down with it. As soon as the drainage was put in order it disappeared. Adding these two deaths to the three formerly reported, there have been in all five persons who died after the operation for genu valgum was performed on them; and in none of these was death due to the operation. The only one which admits of doubt is that one in which diphtheria commenced in the sore over the sacrum, and quickly showed constitutional manifestations.

It may be interesting to note that up to July 31st, 1884, I have osteotomised 1267 limbs belonging to 704 patients, and have performed on these 1800 osteotomies; all for deformities of the lower limbs. The deaths from all causes after these operations are: one from pneumonia (contracted on the eve of operation), one from tubercle of the lungs, one from diphtheria of the respiratory passages, one from diphtheria of bedsore and wounds, and one from enteric fever epidemic at the time in the wards (the two last-mentioned deaths occurred about the same time). The first five were for genu valgum, the last one for genu varum.

Results as to Utility of Limbs.—In all cases there has been improvement in the form, strength, and utility of the limbs of those who have been operated on for genu valgum. Where the knock-knee has been present without complications from other rachitic curves the limbs have been rendered quite straight.

The advantages of the operation and the results may be summarised as follows:—A deformity of a very grave kind has been removed; the height of the patient has been increased, often by several inches; the patients have been able to walk easier, much better, and a great deal further than they could prior to the operation. As a consequence they improved in health and strength, and in many instances they have been enabled to occupy situations from which they had previously been debarred. It would be out of place to give cases in detail, especially as they are numbered by hundreds, but by way of illustration the following may be quoted:—

1. A lad eighteen years of age was affected with genu valgum to such an extent that a horizontal line drawn from the internal malleoli measured eighteen inches, while a vertical line running from the horizontal one to the apex of the knees measured fifteen inches. He could neither walk nor stand for more than five minutes at a time, and was totally unfitted for work. After supra-condyloid osteotomy his limbs were straight; he could walk and leap with ease, the movements of the knee-joints being perfect. He was several inches higher than he was prior to the operation. A year afterwards he several times walked eighteen miles at a stretch without fatigue. He is now engaged as a mechanical engineer, in regular employment, and walks six miles daily in going to and coming from his work. This patient has now been operated on six years. There has never been any weakness of his legs since the operation. He has grown considerably during that time both in height and breadth, and he is a great deal stronger than he was ever likely to be had the operation not been performed.

2. A man twenty-five years of age, affected with double genu valgum (fifteen inches between the malleoli), had to give up his employment some time previous to his admission into my ward on account of his inability to walk to and from his work and difficulty of standing. After supra-condyloid osteotomy his limbs were straight; his knees were freely movable, his stature increased, and he was capable of doing his work with ease. A year afterwards he walked in four consecutive days over 100 miles without fatigue. This man has now been operated on about five years; he is now quite well, and has changed his occupation to that of a traveller for a publishing firm.

3. A third patient, affected with marked genu valgum, could scarcely walk with the help of crutches from his own door to the shop at which he wrought, situated thirty yards distant. There he had a sedentary occupation. After operation, besides having straight limbs which were freely movable, his height was increased, and he was able to walk without any support. He changed his residence, walking then daily four miles to his work. At one time he walked ten miles [illegible] without fatigue. [illegible] also been operated on [illegible] of the supra-condyloid [illegible] genu valgum. In a former paper I have answered the question as to whether the femora grow after supra-condyloid osteotomy. There is abundant proof that the operation does not interfere with the growth of the bone. Many patients, from eight to fifteen years of age, have been operated on, and have now grown considerably, and the femora have grown in proportion with the rest of the body. As an example, one boy aged eight years, affected with genu valgum, measured 4 ft. in height; after supra-condyloid osteotomy he measured 4 ft. 3 in.; four years later he was measured, and found to be 4 ft. 10 in., the femora having proportionately increased.

Relapses to the deformed Condition.—As to relapses to the deformed condition after osteotomy, I have seen in two cases in which osteotomy was performed for anterior curves of the tibia in young children, who were afterwards the subjects of severe illnesses, that the curve recurred; but in genu valgum, after supra-condyloid osteotomy performed by me, I have only once seen a case which showed a return, and that to a very slight extent. It occurred in a boy who had a standing occupation and was poorly fed. Four years afterwards he returned with a slight degree of knock-knee (4 in. between the malleoli, while the knees measured 12 in. from the malleoli).

Average Duration of Treatment.—The average duration of treatment is six weeks in the splints, and two in the wards after that, while learning to walk. The patients are then advised to go to the convalescent home for two weeks. Three months are ample to enable them to be fitted for walking about and to permit them to engage in their occupations again. I have never tried to find the very earliest limit which was necessary to enable the patient to get up and walk about, but rather tried to gain a point which would enable us to say that after that time there was no fear that any mishap would take place.

Combining these statistics of British surgeons with my own, we have 580 limbs operated on by others by the supra-condyloid method, and 804 operated on by myself, which gives 1384 limbs that have been operated on by British surgeons by this method. Of these, ten have died *after*, though not all *from*, the operation. There are only three that are stated to be due to the operation. In one of these cases, however, the operation though credited as Macewen's was not such; so that two only are left: in one the death is clearly due to the operation (septicæmia); while in the other there is a reasonable probability of the operation having been, indirectly at least, the cause of death, the operation having been performed in this instance under bad sanitary conditions.

I have observed in the medical journals within the last few months that there have been some cases in which hæmorrhage has followed the supra-condyloid method; one in which the anastomotica magna, and another in which the popliteal had to be ligatured. One surgeon says that he performed the operation in the usual place for Macewen's operation. He then states that he took his bearings "from the patella." The patella is not given by me as a guide to the place of incision, either in the soft parts or in the bone. It is not a fixed point, and does not bear a constant relation to the plane of the condyles in the deformed condition of the femur. It is probable that if such a guide was taken it might have led some to cut the anastomotica magna or the superior articular. With regard to the division of the popliteal, if the instructions given for the performance of the operation be attended to, it is difficult to understand how it can be divided, except by pure accident. It is, however, possible that it could be divided in one of the following ways. First, by the use of instruments which have a greater breadth than the diameter of the bone. A portion of the instrument might thereby project on the posterior border beyond the bone, and come in contact with the artery. Secondly, by not cutting the bone in a methodical manner, and especially by not attending to the directions given to cut the posterior and inner portion of the bone from behind forwards and outwards. If, instead of this, the osteotome be directed from within outwards and backwards, the popliteal might be divided. Thirdly, by holding the osteotome between the finger and thumb, and more especially when this is done at the head of the instrument alone, while the rest of the handle is left unsupported; the chisel is then apt to slip off the bone, and the impulse which it has already received might cause it to penetrate the artery. This is all the more likely to follow if the surgeon holds the osteotome so as to cut away from, instead of to, himself. Regarding suppuration, it seems to me that the chief point in bringing it about

Digitized by Google

is the exercise of force, either during the operation, or afterwards by tight bandaging. There is another way in which it might happen—viz., by the elastic rod which is sometimes used for arresting the flow of blood in the limb during the operation. This rod may be applied too tightly or too roughly, and so predispose to suppuration.

The placing of the limb correctly on the splints is a point to be attended to in connexion with obtaining perfect results. In any case where it is feared that suppuration might ensue, it would be an element of safety to enlarge the wound to a couple of inches and insert a drainage-tube. In fact, Mr. Lister in performing this operation always does so.

The work of continental surgeons has not been referred to, not that they have been idle—quite the contrary; but the data have not yet been furnished which would enable me to speak with sufficient confidence as to their work. Papers have appeared from the following (among others)—Paul Bruns of Tübingen, Boeckel of Strasburg, Checcarelli Alessandro, Panzeri, Margary, Romano, Morelli, Albertini, Ambrosio, Topai of Italy; and in America we have among others Fowler, Pilcher, and Hutchinson of New York.

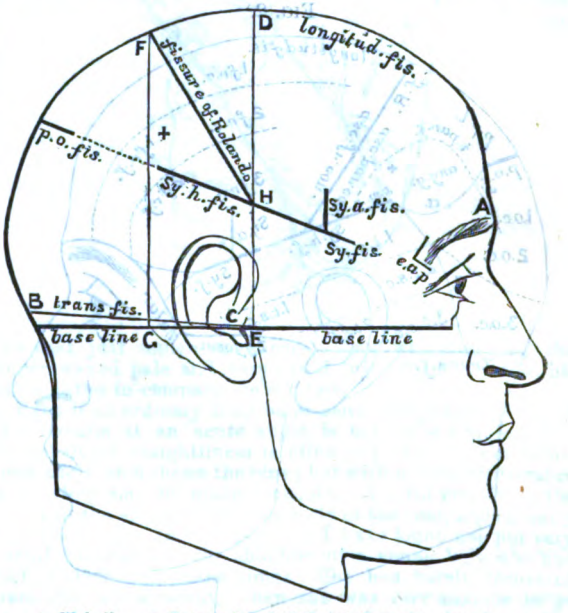
OBSERVATIONS ON THE

RELATION OF THE PRINCIPAL FISSURES AND CONVOLUTIONS OF THE CEREBRUM TO THE OUTER SURFACE OF THE SCALP.

BY ROBERT W. REID, M.D., F.R.C.S.,
LECTURER ON ANATOMY, MEDICAL SCHOOL OF ST. THOMAS'S HOSPITAL.

A GOOD deal has been written about the relation of the sulci and convolutions of the cerebrum to the outer surface of the bony cranium, especially with regard to the various sutures. Frequently these sutures are not to be felt through the scalp, and practically, therefore, such relations are of little value to anyone examining the head from a medical or surgical point of view. Hence it occurred to me that a gap might be filled up in regional anatomy by describing the relation of the principal sulci to the outer surface of the scalp, and consequently I made a series of investigations on the dead body, to try if possible to make out some guides by which, on examining a person's head, one might readily be able to localise the chief sulci, and thereby the position of the principal convolutions. Of course it is impossible to draw a line on the scalp exactly to follow a sulcus of the brain, for the simple reason that the sulci are never in any two brains precisely alike, or the shape of the head exactly the same in all cases. We must also remember that, as the surface area of the outside of the scalp is greater than the surface area of the corresponding part of the cerebrum, any lines drawn on the scalp to represent the sulci will be longer than the sulci themselves, and the spaces between those lines, indicating the convolutions, will be larger than the convolutions themselves.

What I propose to do is to show that by taking large and easily felt landmarks on the head, and drawing from these certain lines, those lines will indicate accurately enough for all practical purposes the position of the principal sulci, and that by removing in any of these lines a piece of the scalp and skull an inch square, or by applying the one inch trephine to the skull, with the centre pin on the line, we can expose the fissure in any part of its course.



The landmarks which can easily be felt on the outside of the scalp, and with reference to which lines can be drawn to indicate the position of the sulci are the glabella, or depression between the two nasal eminences just above the root of the nose, external occipital protuberance, superior curved line of the occipital bone, parietal eminence, posterior border of the mastoid process, depression just in front of the external auditory meatus, external angular process of the frontal bone, frontal part of temporal ridge, and the supraorbital notch. If the last is not to be felt, its position will be at the junction of the inner with the middle thirds of the supraorbital margin. We shall also suppose that the base line (Fig. 1), from which all perpendicular lines are drawn, runs through the lowest part of the infraorbital margin and the middle of the external auditory meatus.

Longitudinal fissure of cerebrum.—This of course is readily indicated by a line running along the middle line of the top of the head from the glabella to the external occipital protruberance.

Transverse fissure.—This is indicated by drawing a line along the superior curved line of the occipital bone from the external occipital protuberance to the external auditory meatus—that is, along the line of junction of the head with the neck posteriorly.

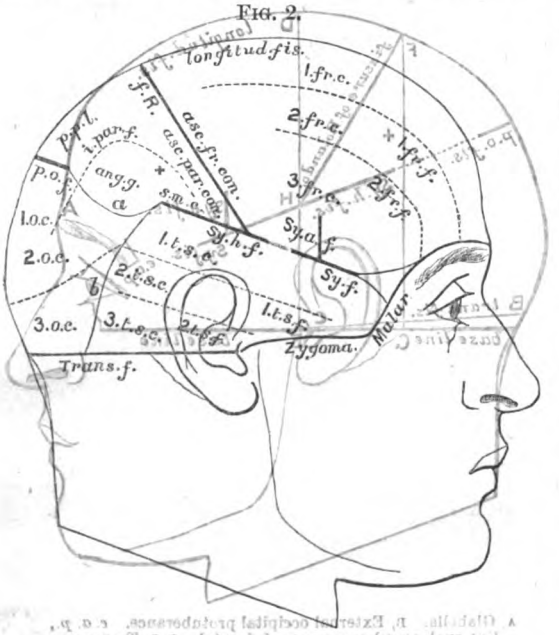
Fissure of Sylvius.—To find this draw a line from a point one inch and a quarter behind the external angular process of the frontal bone to a point three-quarters of an inch below the most prominent part of the parietal eminence. Measuring from before backwards, the first three-quarters of an inch of the line will represent the main fissure, and the rest of the line will indicate the horizontal limb. The ascending limb will start from the posterior end of the line indicating the main fissure—that is, two inches behind and slightly above the external angular process,—and run vertically upwards for about an inch. (See Fig. 1.)

FIG. 1.

A, Glabella. B, External occipital protuberance. *e. a. p.*, External angular process of frontal. B C, Transverse fissure. A B, Longitudinal fissure. *Sy. fis.*, Sylvian fissure. *Sy. h. fis.*, Horizontal limb of fissure of Sylvius. *Sy. a. fis.*, Ascending limb of fissure of Sylvius. D E, Perpendicular line from depression in front of external auditory meatus to middle line of top of head. F G, Perpendicular line from posterior end of base of mastoid process to middle line of top of head. F H, Fissure of Rolando. *p. o. fis.*, Parieto-occipital fissure. + Most prominent part of parietal eminence.

Fissure of Rolando.—To find this and, at the same time, the region of the ascending frontal and parietal convolutions, first indicate on the surface of the scalp the longitudinal fissure and the horizontal limb of the fissure of Sylvius, next, from the base line draw two perpendicular lines to the top of the cranium, one (D E, Fig. 1) from the depression in front of the external and auditory meatus, and another (F G, Fig. 1) from the posterior border of the mastoid process at its root. We shall thus have described on the surface of the head a four-sided figure, bounded above and below by the lines for the longitudinal fissure and horizontal limb of the fissure of Sylvius respectively, and in front and behind by the two perpendicular lines. If we now draw a diagonal line (F H, Fig. 1) from the posterior superior angle to the anterior inferior angle of the space, this diagonal line will lie over the fissure of Rolando. In the majority of cases the fissure of Rolando does not actually run into the fissure of Sylvius, a convolution bridging across at that point; hence the lowest half inch or so of the line would cross this convolution. In those cases where the two fissures join the fissure of Rolando would be indicated by the whole length of the line.

External parieto-occipital fissure.—This fissure is more variable in its position than any of the other principal fissures of the cerebrum, and consequently any indication of it on the



Digitized by Google

surface of the scalp must be approximately accurate. If we continue the line for the horizontal limb of the fissure of Sylvius onwards to the line indicating the longitudinal fissure, we shall find that on trephining over the inner inch of this line we shall expose the external parieto-occipital fissure, or some part of it. In most cases we have seen the whole of the fissure in the opening so made, in others it showed itself in the posterior half of the opening, and in still fewer cases it was seen in the anterior half.

Having now indicated the position of the principal fissures, it will be comparatively easy to map out the areas of the frontal, parietal, temporo-sphenoidal, and occipital lobes, with their chief sulci and convolutions as far as they are in relation with the outer surface of the scalp.

The *frontal lobe* will be bounded above by the line for the longitudinal fissure, below by the line for the trunk and horizontal limb of the Sylvian fissure, behind by the line for the fissure of Rolando, and in front by a line just above and parallel with the supra-orbital margin. A line drawn from the supra-orbital notch backwards to within three-quarters of an inch

FIG. 2.

+ Most prominent part of parietal eminence. *a*, Convex line bounding parietal lobe below. *b*, Convex line bounding temporo-sphenoidal lobe behind. *1 fr. c.*, First frontal convolution. *1 fr. f.*, First frontal fissure. *f. R.*, Fissure of Rolando. *Sy. f.*, Sylvian fissure. *Sy. h. f.*, Horizontal limb of Sylvian fissure. *Sy. a. f.*, Ascending limb of Sylvian fissure. *p. o. f.*, Parieto-occipital fissure. *i. par. f.*, Intra-parietal fissure. *ang. g.* Angular gyrus. *s. m. c.*, Supra-marginal convolution. *1 t. s. c.*, First temporo-sphenoidal convolution. *1 t. s f.*, First temporo-sphenoidal fissure. *1 o. c.*, First occipital convolution. *p. p. l.*, Postero-parietal lobule.

of the line for the fissure of Rolando, and parallel with the line for the longitudinal fissure, will indicate the first frontal fissure. The frontal part of the temporal ridge will indicate the second frontal fissure. The first, second, or third frontal convolutions will thus be mapped out. The ascending frontal convolution will occupy a space about three-quarters of an inch broad parallel with, and in front of, the line for the fissure of Rolando. (See Fig. 2.)

The *parietal lobe* will be marked out by the line for the longitudinal fissure superiorly, and in front and behind by the lines for the fissure of Rolando and the parieto-occipital fissure respectively. Below, the line for the horizontal limb of the fissure of Sylvius will separate it from the temporo-sphenoidal lobe. The interval between the posterior end of the Sylvian line and the outer end of the parieto-occipital line is occupied by the junction of the postero-parietal lobule (*p. p. l.*, Fig. 2) with the first annectant convolution and the angular gyrus (*ang. g.*, Fig. 2) with the second annectant convolution, the arrangement of these convolutions with regard to one another being very variable, the angular gyrus usually projecting somewhat more posteriorly than the postero-parietal lobule. We can therefore only indicate the separation of this part of the parietal lobe from the neighbouring temporo-sphenoidal and occipital lobes by drawing a line (*a*, Fig. 2) slightly convex downwards from the posterior end of the Sylvian line to the outer end of the parieto-occipital line. An irregularly triangular space will thus be marked out to indicate the parietal lobe. If in this space we draw a line from a point half an inch outside the outer extremity of the parieto-occipital line to a point about an inch above and behind the anterior and inferior angle of the space, this line will lie over the *intra-parietal fissure* (*i. par. f.*, Fig. 2). The line must be curved, with its convexity directed forwards and inwards, and parallel in its anterior third or so with the line for the fissure of Rolando, and about three-fourths of an inch behind it. In the space above the intra-parietal sulcus we shall have, in front, parallel with the whole length of the fissure of Rolando, the ascending parietal convolution, and behind, the postero-parietal lobule. The space below the sulcus will indicate, in its anterior part, the supra-marginal convolution (*s. m. c.*, Fig. 2), filling up the most prominent part of the parietal eminence, and, in its posterior part, the angular gyrus (*ang. g.*, Fig. 2).

Temporo-sphenoidal lobe.—This lobe, like the last, is somewhat difficult to indicate posteriorly, because it becomes continuous there with the parietal and occipital lobes without any distinct line of demarcation. Its outline will lie in the lower part of the temporal region, extending a little beyond the temporal ridge behind. It will be bounded above by the line of the main trunk and horizontal limb of the fissure of Sylvius, below by the upper border of the zygoma and a line carried back from the posterior end of that to a point midway between the external occipital protuberance and the posterior border of the mastoid process at its root. The anterior border or apex of the lobe will extend as far forwards as the posterior superior border of the malar bone. Behind, the lobe will be bounded by a slightly convex line (*b*, Fig. 2), with the convexity directed backwards, extending from the posterior end of the Sylvian line to the posterior end of the line indicating the lower boundary of the lobe. A line running about one inch below and parallel with the line for the main trunk and horizontal ramus of the fissure of Sylvius will indicate the first temporo-sphenoidal fissure (*1 t. s. f.*, Fig. 2), and another line about three-quarters of an inch below and parallel with the last will indicate the second temporo-sphenoidal fissure (*2 t. s. f.*, Fig. 2). Thus the first, second, and third temporo-sphenoidal convolutions will be mapped out (*1 t. s. c.*, *2 t. s. c.*, *3 t. s. c.*, Fig. 2).

The *occipital lobe* will occupy the remaining surface of the scalp. It will be bounded above by the parietal lobe, below by the superior curved line in its inner half—that is, the part of the line unoccupied by the lower limit of the temporo-sphenoidal lobe. Internally the line of the longitudinal fissure, and externally the convex line for the posterior border of the temporo-sphenoidal lobe, will bound it. The area of the lobe being marked out, the first, second, and third occipital convolutions can be readily filled in (*1 o. c.*, *2 o. c.*, *3 o. c.*, Fig. 2).

The above description has been taken from a series of dissections made by myself and kindly allowed to be carried on by the demonstrators of morbid anatomy in the post-mortem room of St. Thomas's Hospital. It has been frequently tested on the dead body and found to be accurate, and is merely intended to afford for practical purposes a general idea of the surface of the cerebrum in relation to the scalp. It does not take into consideration the shape of the head in different races, or in those heads which present an abnormal outline from pathological conditions.

Lambeth-palace-road, S.E.

ON A CASE OF POISONING BY SARDINES.

BY AUGUSTUS W. ADDINSELL, M.B.

THERE are few things more embarrassing to the practitioner than to be called upon suddenly to treat a case of poisoning, especially when it is not quite clear what the poison is. The rarity and gravity of the following case make it, I think, worthy of record.

On Tuesday, June 17th, at 7 P.M., I was hastily sent for to visit a lady who was vomiting very severely. I went immediately, and the husband told me the following details:—At 3 P.M. Mrs. A—— had taken for luncheon some brown-bread-and-butter and four sardines, which were the remnant

Digitized by Google

of a box that had been opened some days. She had noticed a small speck of white on one or two of them, but had thought nothing of it. Almost immediately she commenced to yawn, but, being tired with nursing some children lately with measles, this was overlooked; the yawning, however, increased towards 4.30 P.M., and from that time became incessant, until it culminated in an act of vomiting. She was then seized with diarrhœa and violent abdominal pains. Between 5.30 and 6.30 P.M. she vomited five times, and had seven evacuations of the bowels. I found the patient much prostrated; no pulse could be detected in any of the superficial arteries but the temporal, and there very feebly indeed; a cold clammy sweat bedewed the face, which was perfectly colourless; the eyes were much sunken and the pupils contracted, the mouth very parched, the lips perfectly livid, and great thirst was complained of, with severe pains in the umbilical region and cramps in both lower extremities. The mind was a little wandering, though she fully recognised me. The temperature was 97·2°. Though she was scarcely able to speak for yawning, she pleaded piteously for water. I gave her ice to suck and placed hot flannels with turpentine over the abdomen, which relieved the pain for the instant only. This not producing any permanent relief, and the evacuations continuing every quarter of an hour, I injected three minims of morphia hypodermically, and gave one drachm of brandy with ice. At this time (7.45) she was fainting, and the collapse seemed more complete. I administered another drachm of brandy, which was vomited in ten minutes. I had previously ordered the vomited and evacuated matter to be kept, and I found the latter consisted entirely of blood and mucus. The former merely contained water and the brandy. By nine o'clock the cramps had ceased, and there had been no vomiting and but one evacuation during the last hour. The temperature had remained all along subnormal and the yawning had persisted. I then gave half a pint of rice-water with an egg beaten up, with some ice to allay the thirst, which was causing great agony. By 11.30 P.M. the pulse had returned so as to be felt at the wrist; the temperature had gone up to 99·2°; in the next hour she vomited once, and had two motions of the same sanguineous description. By 1.30 A.M. the temperature was down again to 97·4°, and the pulse distinct though very feeble. During the night the patient slept fitfully, but vomited twice and had three motions by 9 o'clock in the morning. Bismuth and carbonate of potash were then prescribed, with plenty of rice-water and egg, which was taken freely during the day. At noon on the Wednesday, seventeen hours after I first saw the patient, the temperature was normal; the pulse fairly full. There was no pain, and the patient felt comparatively well, though of course very weak. From this time she rapidly recovered, and is now perfectly well again.

It seems to me that the great interest in this case lies in the violence of the symptoms (for certainly not less than six pints of liquid and bloody evacuation were passed in a few hours) and the rapid recovery; one was naturally on the look out for enteritis and peritonitis to supervene, but no approach of these disorders could be detected. Primarily, I consider the vomiting, by removing a portion at least of the irritant matter was beneficial to the patient, and that the subsequent morphia injection had the effects for which I gave it—viz.: (1) To allay the pain; (2) to stop the cramps; and (3) to arrest peristalsis. Had this not been done and the diarrhœa allowed to continue, I think the patient must have succumbed. Now the question is, What was the exciting cause? The oil being rancid could scarcely account for it, and besides, but a very small quantity of oil was taken. It has been proved in a rather recent case that tin (Professor Attfield in a paper read before the Pharmaceutical Society, 1883) in sufficient quantity to poison would be so extremely objectionable that the patient would have refused to take it; one is therefore forced, *per viam exclusionis*, to the conclusion that it must have been the sardines which had caused the mischief, and as the box had been opened some time, and others had been taken from it with no evil results, it becomes an interesting and important question for the profession, as well as for the public, how long it is safe for a box of sardines to be open and in use, and what the precise nature of the poison is to which they become subject. That it is an irritant, and a very strong one, is clear from the foregoing account; but as far as I can gather this is the first case reported of the evil, and as it arose from the use of such a very popular article of diet, I thought it worthy of being brought forward.

Talgarth-road, West Kensington, W.

A PIN SLING.

BY SAMPSON GAMGEE, F.R.S.E.,
CONSULTING SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

A GENTLEMAN consulted me the other day, for a painful condition of the tip of his left little finger. To secure the benefits of physiological position and immobility, I bent the elbow at an acute angle and raised the hand; then, pinching up the sleeve at the wrist, fixed it to the coat by a strong safety-pin; with another I attached a fold of the sleeve to

the coat just under the elbow. Rest was absolute; the finger waxed pale and easy; and my patient went to his office duties in comparative comfort.

Even if an ordinary sling be at hand, the process of fixing the forearm at an acute angle is not quite simple; and the resulting unsightliness is often unpleasant. For clearness, the sketch shows the pins; but with a little contrivance a pin sling may be made invisible. A third pin, fixing the inside of the arm sleeve to the body of the coat, adds greatly to immobility. In this position I have found one pin very useful, in steadying the shoulder of a young lady who had had it dislocated three times. She had barely recovered *from* the last accident, when she was very anxious to go to a ball. By fixing, with a safety-pin, the inside of the sleeve to the bodice, a trusty, yet invisible, checkmate was provided, allowing freedom of hand, but barring abduction. These are trifles, only noted apologetically, because *pro re nata* they may be useful.[1]

Birmingham.

CEREBRO SPINAL WHITE LINE.

BY JAMES OLIVER, M.B. EDIN.

THE term white line I employ to designate a condition of skin produced in the same way as the "tache cérébrale" of Trousseau, but its direct opposite, and dependent on a spasmodic instead of a paralytic state of the capillaries. The capillary wall, although devoid of anything like a distinct muscular coat, such as can be demonstrated in the larger vessels, is nevertheless capable of being acted on, dilating or contracting according to circumstances. To a certain extent the minute blood channels may resemble an ordinary elastic tube, varying in width according to the amount of pressure exerted on their walls by the contained fluid. That, however, they have more than a passive existence in the animal economy there can be little doubt. It must still remain a debated question whether they are or are not governed by a special nerve influence. The minute structure of the capillary wall is a simple one, being a single layer of cells, epithelioid in character, and continuous with the similar layer of cells

[1] While correcting this proof, I find that Research (The Surgeon's Hand-Book by Clutton, p. 58) has made slings by pinning up the skirt of the coat, or the coat and shirt-sleeve; but the pin sling as sketched above seems likely to commend itself for simplicity and effectiveness

Digitized by Google

lining the larger vessels. The epithelioid cells of capillaries in process of development have been seen to vary in shape. We are, therefore, justified in concluding that they are most probably protoplasmic in nature. The protoplasm of the bloodvessel is the same as the protoplasm of muscle, only less active, and this lessened activity is altogether due to the character of its limiting membrane. The application of dry faradaism to the skin exerts for the time being an apparent paralysing influence on the healthy capillary wall. Should, however, the epithelioid cells be already altered by some morbific change, the paralytic condition is more apparent and more lasting. In many cases the use of the faradaic brush prevents the production of white line in the most marked cases for at least an hour after its application. That the protoplasmic masses are not readily acted on is evidenced by the fact that twenty seconds as a rule elapse before they respond to the pressure influence. The condition may be one belonging to the category of reflexes. I am, however, inclined to believe it is due to an inherent contractility of the cells. The cells acted on alone contract. In some cases heat appeared to aid in the production of the phenomenon, and rendered the white line more likely to be obtained on the body than any of the extremities. In cases of progressive muscular atrophy, associated with well-marked fibrillary twitchings and no pain, the white line was readily produced all over the body, even on the scalp. It is not, however, obtainable in all cases of progressive muscular atrophy. It is quite possible that whilst many cases of this disease may, and apparently do, depend on central change existing in the nervous system, others are primarily due to a change in the muscle itself.

Montague-street, W.C.

A CASE OF
AUTOGENETIC PUERPERAL SEPTICÆMIA, WITH REMARKABLE EXACERBATIONS AND REMISSIONS; RECOVERY.

By H. S. REYNOLDS, F.R.C.S.E.

MRS. P——, primipara, was confined, after a natural labour, on the 9th of August last. The loss after the labour was very scanty. Next morning the temperature was 102°, pulse 125; great pain over the area of the left ovary, with unmistakable peritonitis; lochia still very scanty. Evening temperature 104°; pulse 125. I ordered quinine, half a grain of opium every two hours, and hot fomentations. She had temporary paralysis of the bladder, necessitating catheterisation twice daily. She remained in this condition, with exacerbations and remissions, for four or five days. On the third day she had a rigor; pain was still felt over the left ovary, and then appeared over the right, necessitating the continuance of the opium. On the fifth day the temperature was 105°; on the 6th, 105·4°. I gave her large doses of quinine, which had a very beneficial effect. On the ninth day, for the first time, the temperature and pulse went down to normal. I have omitted to say that, contrary to my anticipation, the breasts failed in the ordinary course, and I had them drawn twice daily. The pain over the ovaries gradually subsided. There had also been considerable tympanites, which subsided also. The bowels were in a relaxed condition from about the fifth day. From the ninth to the eleventh day the temperature and pulse went up till they were 105° and 125 respectively, and she had a severe rigor, lasting half an hour. Next day the temperature was 106°, both temperature and pulse dropping the following day to normal, although the skin acted profusely and the tongue was moist and clean.

Remarks.—I consider the septicæmia autogenetic in origin, as I have not had any cases of erysipelas or zymotic diseases in my practice, neither are there any cases in the village in which the patient lives calculated to produce such symptoms. I am at a loss to account for so severe a rigor appearing so late as the ninth day, as I surmised it certainly was too late for further septic absorption, and since which rigor the patient has gone on well towards recovery, and at the present time is in a satisfactory condition. One of the remarkable features of the case was the almost entire absence of lochia.

Castle Donington.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

GUY'S HOSPITAL.

TWO CASES OF EXTRACTION OF CATARACT IN WHICH THE EYE FIRST OPERATED ON SUCCESSFULLY WAS LOST FROM SYMPATHETIC OPHTHALMITIS, FOLLOWING UNSUCCESSFUL EXTRACTION IN THE SECOND EYE.

(Under the care of Mr. C. HIGGENS).

CASE 1.—Sophia H——, aged sixty-seven, was admitted on May 2nd, 1881. Cataract had been extracted from the left eye by small flap section upwards with iridectomy on February 7th, 1876; iridectomy downwards was performed at the same time in the right eye.

On March 20th, 1876, the vision of the left eye was $\frac{2}{60}$ with + 3-inch lens, and Snellen No. 3½ with + 2½ inch.

On the date of admission (May 2nd, 1881) the cataract was extracted from the right eye by oblique corneal section downwards. At the end of the third week the pupil was entirely blocked by inflammatory material; there was no anterior chamber, the eye had perception of shadows.

The patient left the hospital shortly afterwards, but returned on August 8th with severe iritis in both eyes. The right eye was excised. The left eye improved somewhat after excision of the right, but the improvement was not maintained. On September 20th the pupil of the left eye was entirely adherent. The eyeball eventually shrunk.

CASE 2.—Thos. McT——, aged seventy-five, was admitted on July 23rd, 1883. Iridectomy had been performed in both eyes, upwards in the left and downwards in the right on June 12th, 1882, neither cataract being at that time mature. Extraction by small flap upwards had been done in the left eye on July 10th of the same year. Subsequently (Nov. 6th) an operation for spasmodic entropion was performed on both sides. On Nov. 13th, the vision of the left eye was $\frac{5}{60}$ with + 13 dioptres (Jaeger). No. 12 with + 16 dioptres.

At the date of admission (July 22rd, 1883) extraction by small flap downwards was performed, the vitreous humour escaped before the cataract, which was removed with a sharp hook. Much soft matter was left behind. Severe iritis supervened.

Nov. 30th.—The globe was shrinking, and there was no perception of light.

In January, 1884, the patient presented himself with sympathetic ophthalmia well established in the left eye. When last seen in May of this year the eye was soft and shrinking.

RADCLIFFE INFIRMARY, OXFORD.

CASE OF SUNSTROKE; NECROPSY; REMARKS.

(Under the care of Dr. W. TYRRELL BROOKS.)

FOR many of the following notes we are indebted to Dr. Street, late senior resident medical officer at the infirmary.

John M——, aged twenty-nine, was admitted into the infirmary on August 10th, 1884. From his friends it was gathered that he had been doing harvest work at Windsor, and on the evening of the 8th had walked thence to Wolvercote (a village near Oxford), which he reached on the afternoon of the 9th. After resting a short while and taking some bread-and-butter and tea, he set to work reaping, and worked about two hours when the rain compelled him to stop. In the evening he had a meal of bacon, bread, and beer, and after walking about for a short time he went to bed in a loft. Early the next morning (about 4 A.M.) a man sleeping near him noticed him rolling about, and at 6 A.M. he was found in an unconscious state with froth issuing from his mouth. He was then taken to the infirmary.

On admission he was comatose, with his face congested; his eyes closed; his conjunctivæ insensitive; his pupils equal, dilated, and not reacting to light. Reflex action was totally abolished, but the sphincters of the rectum and bladder were unaffected. Respiration was laboured and

Digitized by Google

stertorous, the diaphragm and the interepetals not working rhythmically. On listening over the lungs a few râles were heard, but the respiratory sounds were masked by the loudness of the stertor. The pulse was regular and full, and no abnormal sounds were detected over the heart. The number of pulse beats per minute was 72; the respirations were 136 per minute; temperature 102·4°. The bladder was distended and a large quantity of urine was drawn off by the catheter, which did not contain either albumen or sugar. The contents of the stomach were drawn off, and that organ washed out with tepid water. The stomach contained a small quantity of dark-brown fluid with shreds of leaves in it; there were not any solid masses of undigested food. The surface of the body was clammy and warm; the superficial vessels, especially the veins, being much congested.

The patient died in three hours after admission from failure of respiration, the pulse persisting a short time after the respiratory movements had ceased.

At the necropsy the surface of the body was found to be livid and rigor mortis, which came on before four hours after death, had passed off. On removing the calvaria the sinuses of the dura mater were seen to be full of fluid blood. The pia mater did not show anything abnormal, except at the base of the brain, where it was opaque in places, especially within the circle of Willis. The cortex of the brain was congested; the substance was firm but presented a number of bleeding points where cut. The medulla was sliced, but no abnormal appearance discovered. The lateral ventricles contained about two ounces of cerebro-spinal fluid, but no clot. The lungs were emphysematous, the large veins filled with black fluid blood, the heart being entirely empty. The remaining organs of the body were healthy.

Remarks by Dr. BROOKS.—This disease falls, I think, under the second category of Sir Joseph Fayrer's classification of sunstrokes—viz., those in which there is a profound disturbance of the nervous centres, due to the combined influences of heat and exhaustion. It was elicited at the coroner's inquest that the patient had had a sunstroke many years before, which had left as its sequela a certain amount of cerebral irritability; thus, although he had been in service as a butler, he was unable to take alcohol, even in small quantities, without losing more or less self-control. He was, however, not in fear of the sun, as he had been working in the harvest fields during the very hot weather. The amount of fatigue he underwent may be estimated by the fact that, after reaping at Windsor he walked a distance of over thirty miles, and after only a short rest recommenced work; the weather during the time was exceedingly hot until the evening, when rain came on, and there was a considerable amount of moisture in the air owing to the rapid evaporation. The full effects of the sun do not seem to have been manifested as long as the air was dry and evaporation from the surface of the body considerable; when, however, the air became moist and the evaporation from the body somewhat checked, the powerful action of the heat in the man was shown. His case was, as far as I know, the only one near Oxford (certainly the only one brought to the infirmary) during the past summer, and he would be a subject in whom there existed a predisposing cause on account his former attack. The thickening and opacity of the pia mater at the base of the brain were of old standing, the result probably of the former attack. The failure of respiration, I think, was due to some changes taking place in the respiratory centre. The vagus was not affected so far as its cardiac fibres were concerned, the heart beat being normal both in frequency and rhythm. The want of coördination in the muscular mechanism of the respiratory act would point to the involvement of the respiratory centre rather than to any affection of the vagus. There was not any engorgement of the lungs, and both sides of the heart were empty and contracted. This emptiness and contracted state of the heart might be due to tonus of the cardiac muscle brought about by the heat and analogous to the heat tetanus of ordinary skeletal muscle.[1] It seems probable that the comatose condition was preceded by convulsions, though little can be said on this point, as the fellow-sleeper of the man was extremely unintelligent, and could not give any trustworthy account of the period before the man became unconscious. The lividity and congested appearance of the surface of the body, together with the fulness of the venous system, point to a relaxation of the arteries due to some vaso-motor paralysis. The rapidity of the onset and disappearance of the rigor mortis is what might have been expected from the exhausted state of the patient. I do not know if any explanation of the post-mortem fluidity of the blood in such cases has been advanced. It appears a curious circumstance that of the two important coagulable substances in the human body—viz., blood plasma and muscle plasma—that in the case of the one the power of coagulation should be diminished, whilst in that of the other it should be increased.

[1] Vide Sir Joseph Fayrer on Sunstroke.

THREE COUNTIES ASYLUM, ARLSEY.

PASSAGE OF A SPOON AND OTHER FOREIGN BODIES THROUGH THE ALIMENTARY CANAL.

THE following case, for the notes of which we are indebted to Mr. S. E. De Lisle, senior assistant medical officer, is worthy of record, as showing the capabilities of the alimentary canal for the passage of foreign bodies of even a large size.

S. P——, a delicate-looking woman, aged thirty-two years, was admitted a patient in November, 1882, into the asylum, in a state of acute melancholia. She was actively suicidal, having attempted to kill herself by thrusting things down her throat and by starving herself.

About six weeks after her admission she succeeded in evading the watchfulness of the nurse placed in special charge of her, and snatching a teaspoon from the table, instantly swallowed it. The spoon was 6 in. long, 1¼ in. wide in the bowl, and weighed 7 drs. 20 grs. She subsequently succeeded, although specially watched, in tearing pieces varying from 4 in. to 6 in. square from her blanket and swallowing them. This was discovered by the holes being noticed in the blanket and the pieces subsequently found in her stools.

In April, 1883, four months after she had swallowed the spoon, whilst walking in charge of two nurses she suddenly broke from them, picked up a stone from the ground and swallowed it. About four days later she passed it. The stone weighed 4½ drs. and was about 1½ in. long and 1 in. broad.

In March of this year, fifteen months after she had swallowed it, she passed the spoon per rectum. It was found to have lost size and weight, its dimensions now being, length 5½ in., width of bowl 1½ in.; weight 5 drs. 11 grs. It will thus be seen that the spoon lost ½ in. in length and 2 drs. 9 grs. in weight during its passage through the body.

On August 7th she swallowed a large steel thimble, which she snatched from a nurse sitting beside her. This she passed on the 11th.

Note.—It will be noticed that while the spoon was in her stomach and intestine she passed through her several foreign bodies of various shapes and sizes; also that the pieces of blanket, the stone, and the thimble all took about the same time to pass through the alimentary canal—namely, four days. The spoon was made of the composition known as Britannia metal. During the time it was making its way through the intestine her condition was variable. She suffered from jaundice for a considerable period, with pain and tenderness over the right hypochondriac region. It seems as if the spoon lodged in this situation for a long time. Her condition then was critical. She persistently refused food, and was fed with the œsophageal tube. She then improved and gained weight, and seemed free from pain or inconvenience till the spoon appeared to have reached the right inguinal region, when she became very ill. She again improved after some time, and seemed to suffer no further distress. The treatment adopted was rest, with opium and belladonna and soft pulpy food. Constipation was relieved by enemata.

A NARROW ESCAPE.—At Bridgewater on the 5th inst. a labourer fell into a trance, and his wife, thinking he had died suddenly, made preparations for the funeral. The vicar, however, on being informed of the facts, inspected the supposed corpse, and refused to allow it to be buried, since it was not cold enough to satisfy him that actual death had taken place. The body was placed in a coffin and conveyed to the church, where it was frequently visited by the vicar and others. On the 8th inst. a slight movement occurred, the man was removed to bed, and has since slowly recovered.

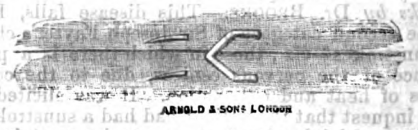
New Inventions.

RICHMOND'S PREPUCE DILATOR,

FOR THE TREATMENT OF PHIMOSIS WITHOUT OPERATION.

THE only method of treating phimosis, in common practice, is by operation. There are, however, a great many patients suffering from this malady who absolutely refuse to undergo any operation for its relief. Numbers of cases are constantly presenting themselves of men considerably advanced in years who have never been able to get their foreskins back, and have consequently suffered continually from discharges attributable solely to the irritation attendant on this condition. Yet many such patients will rather pass their lives with the inconvenience and risk which this state of things involves than submit to the knife. There can, however, be only one other possible means of treating phimosis, and that is by stretching the prepuce. But this method appears to be very seldom put into practice, for when it is tried it generally results in failure. I can see no reason, however, why the skin and mucous membrane surrounding the glans penis should not be as freely dilatable as in other parts of the body. The reason of the failure, I take it, is simply that no proper instrument has been invented for the purpose. Extemporised instruments, such as dressing forceps, aneurysm needles, or blunted hooks, are painful and inadequate dilators. An instrument proper for the purpose should (1) possess blades which could be introduced separately;



(2) the blades must be of suitable size and shape to suit the case; and (3) it should be possible to open them parallel to one another or at any angle. The instrument which I have devised for this purpose consists of two rods, A B, connected together by means of two long screws, C D. At one extremity they are bent inwards and fixed to the blades, E E. These blades can be removed and may be of any size and shape. The rod, B, is of a tuning-fork shape with the screw-nut, M, sliding in the groove between the two branches of the fork. Through the nut, M, is passed the long screw, C, the end of which is received into a cup working on a hinge joint attached to the cylinder, K, which slides along the bar, A. The screw end may be detached from the socket by pressing a little spring. The blades are passed separately down between the foreskin and glans. Very small blades are used at first, and they are of course previously oiled to facilitate their passage. They are then attached to the rods, which are united by fixing the end of the screw, C, into the cup-joint, K. The other screw rod, which is fixed only to the bar A by a joint, can be pulled over into the groove of B. Gradual extension can then be applied by turning the nuts M and N. Since there is a joint at K the blades may be opened parallel to one another, or at any angle, and in fact the relative position of the blades may be altered in any direction. The idea is not to stretch the foreskin forcibly, and at one sitting, but to dilate it gradually in the same manner as a stricture of the urethra is dilated by repeatedly passing a catheter. If the instrument be used once or twice a week for about ten minutes at a time, the foreskin will in most cases go back in a month or six weeks. The larger blades are used to thoroughly stretch the tissues and complete the treatment. The foreskin may thus be dilated to any reasonable extent, and will after a time easily roll back over the corona. The instruments are made by Messrs. Arnold and Sons.

St. Bartholomew's Hospital. W. STEPHENSON RICHMOND.

A NEW FORM OF SUTURE.

I BEG to submit to the notice of the profession a form of suture which in my opinion would be useful, and might in certain cases and in certain situations supersede with advantage the ordinary means of approximating the edges of wounds. I am not aware that such a contrivance has been used before, although the age of the thread suture and the absence of recent attempts to modify its principles of fixation would seem to indicate that it has reached the stage when modification is unnecessary and impossible. Nevertheless, the suture is objectionable in ways which will immediately suggest themselves to anyone who reflects for an instant on its application. 1. It fails to approximate the walls of a wound in a desirable manner, only too often bringing into contact the limited superficial portions of the tissues corresponding to where the threads are inserted, and leaving the deep parts unapproximated. 2. There is a circular constriction, which frequently leads to ulceration and

strangulation of the tissues enclosed within it, and thus to uselessness of the suture; while this defect is not at all times caused by a too tight application, but is indirectly owing to the smallness of the body which bears the strain of the tissues. 3. The suture acts as a foreign body in the wound, and causes those conditions which are known to prevent early union. These not being imaginary objections, but based on experience, I wish to suggest the following form of suture as fulfilling indications not met by the ordinary interrupted suture, and being at the same time easy of application. These sutures may be very readily introduced by a torsion forceps, which is made to grasp the V-shaped bend, while the fingers of the left hand approximate the edges of the wound; after which, if the wound is not thoroughly closed, the wire may be clamped at the bend and the points brought closer together, with or without being held by a thread, or a piece of cork fastened on them. A piece of folded lint may then be applied under the bend to afford support to the wound. The sutures may be introduced either in the long axis of the wound, which is preferable; or across it, when a foreign body would of course be present. These sutures may be had of various thicknesses, sizes, and curves, with lancet points. They are made of silver, with hardened points, by Messrs. Arnold, of Smithfield.

JAMES MAC MUNN,

Finsbury Park. Late Res. Med. Officer, Gt. Northern Hosp.

A NEW TRACHEOTOMY TUBE.

THOUGH gum elastic has, I believe, been used for tracheotomy tubes, hitherto all attempts have been failures. For the tube I now bring before the profession I cannot of course promise a success, but on theoretical grounds, as well as having received approval when a friendly criticism has been asked from distinguished members of the profession, I am induced to publish the results of my endeavours. I believe that of all tubes now in use, Mr. Durham's lobster tail, and the indiarubber tube of Mr. Morrant Baker have the most general popularity, the aluminium, the other silver, celluloid, vulcanite, &c, being found inferior in one or other respect. For the lobster tail, durability, the rectangular curve, its method of introduction, and its movable shield give it special advantages, but it is very costly, complicated, heavy, and prone to produce ulceration and irritation. The indiarubber tube is light,

Digitized by Google

soft, and consequently unlikely to irritate or ulcerate, and cheap; but its thickness, especially if on a webbing, its tendency to rot, collapse, and fall to pieces if not on a webbing, render it very unsafe, while it cannot be used from the beginning. In the gum-elastic tube I have sought to achieve all the virtues, while reducing to a minimum the disadvantages, of the other tubes. Messrs. Baker, of 243, High Holborn, have successfully made some under my direction. They are constructed of the thinnest material that can be made on a webbing (the shield and tube can be made in one piece), are very light, simple, and compressible when warm, but to a degree far short of collapsing, thus enabling them readily to accommodate themselves to the shape of the trachea and its movements, while their webbing framework will keep them from rotting and falling to pieces. They are very cheap, and as no mould is required as for indiarubber tubes, any modification of shape can be adopted according to the fancy of the surgeon. Those I have had made are rectangular, the tracheal end slightly incurved, with a small shield having lateral processes, varnished both inside and outside, and, provided due care be taken with their preparation and keeping, will, I believe, be always found clean and not sticky. I have

tried some other shapes, but I think that the one shown in the engraving, and just described, will be found the most useful. The engraving shows the tube a little tilted to one side. Those who have tied catheters in the bladder will know how much the best the gum-elastic catheter is for the purpose, and I may say it was that fact that first suggested to me the use of gum elastic for a tracheotomy tube. Finally, as regards its use: When desired, it can be used immediately in conjunction with a lobster-tail inner tube, the latter to be left off as soon as convenient. And though this may increase its bulkiness and weight, yet it will not do so to such a degree as to impair its utility. But believing as I do that Mr. G. Bird's dilator is the best instrument in general for the first few days, especially in croup and diphtheria, its use would then be limited to those cases in which a tube has to be worn for a long time—e.g., after injuries of the larynx and other parts of that region, tumours, some inflammatory diseases, and during and after some operations upon the tongue and jaws, when tracheotomy is deemed advisable. Messrs. Baker are preparing tubes in different sizes, so as to make sets.

A. REA EDWARDS, M.R.C.S., L.R.C.P.
Late House-Surgeon King's College Hospital.

THE ANTIDOTE BAG.

MR. MARTINDALE, of New Cavendish-street, was the first to adopt a suggestion to produce a bag fitted with every remedy and appliance likely to be needed in the treatment of a case of poisoning. A notice of this really useful innovation appeared in these columns three years ago, and since that time other similar bags have been devised. Mr. Martindale has further improved upon his by omitting some articles, as the stomach-pump, enema, catheter, &c., which are always at hand, and has thus not only rendered the bag more portable, but has been enabled to supply it at a greatly reduced cost. This smaller bag contains the following antidotes, which are labeled with directions for their use,—viz., dialysed iron, syrup of chloral, chloroform, aromatic spirit of ammonia, spirit of chloroform, oil of turpentine, acetic acid, tincture of digitalis, nitrite of amyl capsules, sulphate of zinc, ipecacuanha, bromide of potassium, calcined magnesia, tannin, and a hypodermic case with syringe and solutions of acetate of morphia, apomorphia, nitrate of pilocarpine, sulphate of atropia, and nitrate of strychnine. The bag is supplied with a copy of Dr. Murrell's "What to Do in Cases of Poisoning."

MICRO-ORGANISMS OF YELLOW FEVER.

IT will be remembered that Dr. Domingos Freire is the author of several communications founded on investigations directed to prove that yellow fever is a contagious disease which owns a micro-organism as its proximate cause. A few weeks ago (THE LANCET, July 29th, p. 29) we published an abstract of some experiments by Messrs. Mozley and Harrison, which went to prove that none of the conclusions at which Dr. Freire had arrived were correct. The latest phase of this discussion is a communication sent to us by Dr. Freire himself, and we propose to give here a *résumé* of his latest arguments and observations.

He thinks that the divergence in results is to be attributed to the widely different conditions under which their experiments were carried out. In the first place, Messrs. Mozley and Harrison injected into the animals liquids obtained by cultivating the earth taken from the graves of persons dead of yellow fever, whilst Dr. Freire employed the earth itself a few minutes after it had been merely diluted and mixed with pure water. It is contended that the particulate liquid injected by Dr. Freire was of great virulence, whereas on cultivation the virulence steadily diminishes. Further, the earth used by Dr. Freire came from individuals dead hardly a year, whilst the material employed by Messrs. Mozley and Harrison had lain three times as long. It is likely that the organisms would in that time have perished, the dead bodies having been reduced to little more than the condition of a skeleton; the more so as the bodies buried in coffins were separated from the earth which covered them by a layer at least of a corrosive substance (lime). In Dr. Freire's experiments the bodies were not surrounded with lime, and were not buried in coffins.

The two authors did obtain fatal results when material was taken immediately from the dead bodies; yet they were not inclined to look on the cause of death as due to yellow fever, but rather to a form of septicæmia. Dr. Freire, however, believes that in their experiments the micrococcus xanthogenicus was the agent in the production of the fatal disease, and he asks how it was, supposing the disease to have been septicæmia, that no bacteria were discovered in the blood. He perceives many lacunæ in the researches made by Messrs. Mozley and Harrison, and is curious to know whether they discovered in the earth employed the micrococcus which he has described as characteristic of yellow fever. He further argues that it is impossible for all guinea-pigs to manifest the symptoms of yellow fever, because species makes a difference, and may profoundly modify morbid processes. Moreover, accurate descriptions of the conditions of all the viscera in guinea-pigs dead after inoculation with the peculiar earth are wanted, and these, with fresh evidence in support of his views, are about to be published by Dr. Freire, who has kindly sent us some of the proof-sheets in advance. In the first autopsy of a guinea-pig inoculated with some drops from a mixture of water and earth taken from the cemetery of Jurujuba, where individuals dead only of yellow fever are buried, the following lesions were noted:—Slight tint of jaundice over the skin of the animal; the brain of a decided grey colour; the lungs congested, and their surfaces studded with black areas; the heart dilated, and containing blackish blood in the ventricles; the liver swollen and blackish; the spleen also dark-coloured; the stomach full of food, and its mucous membrane of a yellow colour; the intestines of a yellowish tint at certain parts and brownish in others; the kidneys swollen and congested; the urine albuminous; and the bladder full. A second necropsy was made, with similar results, on a guinea-pig, which had died after injection of some blood of another guinea-pig, which had lived in a confined atmosphere saturated with the spores of micrococcus xanthogenicus taken from the cemetery of Jurujuba. In all the post-mortem examinations Dr. Freire has found the same morbid changes, with yellow scattered granules and cryptococci of various sizes, shapes, and colours on microscopic examination of the blood. And here Dr. Freire ceases for the present, in the hope that Messrs. Mozley and Harrison will repeat the same experiments with all the necessary precautions.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 27, 1884.

THE near approach of October reminds us that educational work must soon begin again; and it begins this year, it must be admitted, under somewhat new circumstances—circumstances which throw upon the medical authorities unusual responsibilities. The Medical Council is to meet on the 7th of October. All the later meetings of the Council have been held with a halter round its neck. This curiously constituted body, in which the Apothecaries' Society of Ireland and the Glasgow Faculty of Physicians have as much representation as the University of London and twice as much as the University of Edinburgh, has been threatened with wholesome change ever since attention was directed to its composition. For two years past the Government has been trying to pass a Medical Bill that would abolish the individual representation of bodies which are pecuniarily interested in medical licensing, and to substitute a Council in which they should be collectively represented, and confronted with representatives of the Crown on the one hand and of the profession on the other. The complete failure of these attempts, and the exhibition of the Government—the strongest Government of recent times—being at the mercy of gentlemen of the Home Rule party, who have condescendingly given out that they will allow the Bill to pass on the slight condition of sixty or seventy amendments, and of other exacting gentlemen, of whom better things might have been expected, have for the present disheartened, almost to despair, those who ventured to hope for medical reform. The failure of the Government, and the proved incompetence of Parliament, with its present Rules of Procedure, to deal intelligently and effectually with the reform of our licensing system, may well embolden the existing bodies to conclude that they are their own masters, and that Parliament neither knows nor cares how they execute their trust or discharge their duties towards medical students on the one hand and the public on the other.

The ostensible duty of the Medical Council at its approaching meeting is to elect a President. It is vain to speculate on the action of the Council in this matter. Sir HENRY ACLAND has served the Council long and well. He was for years only too complacent towards that body, of which he has been a member from its creation. But of late he has faithfully testified that in his judgment legislation was essential, and that only such legislation as was proposed in the recent Bill of the Government could quiet the disturbed state of medical education, and reduce to a reasonable and more uniform shape the increasing mass of knowledge which our students are required to produce at the examining boards. It will be very interesting to hear what Sir HENRY has to say on the collapse of the Government's efforts to effect even that portion of medical reform which has been proposed in every Bill, by whatever party or by independent members, since reform was first attempted—viz., the consolidation and conjunction of the bodies for licensing purposes. Sir HENRY ACLAND has more to gain by a stout and determined refusal to betray this fundamental principle than he can gain by giving way to those bodies which cannot look at this subject in any other than a parochial and commercial light.

It is too much, however, to expect that these bodies will not see their opportunity in this practical defeat of the Government by its *quondam* colleague, Sir LYON PLAYFAIR. And one result possibly will be, that at the approaching meeting the Council will be asked to sanction a conjunction of the English Colleges, as it has already sanctioned a conjunction of the Scotch corporations. By effecting voluntary combinations, the corporations hope to abolish the demand for combinations enforced by law. There is every reason to believe that the combination of the two English Colleges now contemplated is the same as that set forth in the scheme presented to the Council in March last, by which the College of Physicians and the College of Surgeons respectively undertake to "abstain, so far as allowed by law, from the exercise of its independent privilege" of licensing, to co-operate in the appointment of a board of examiners in this division of the kingdom, and in conferring upon every candidate who shall pass the series of three examinations, two diplomas—the licence of the Royal College of Physicians of London, and the membership of the Royal College of Surgeons of England—for the modest sum of £36 15*s.*—a few shillings more than the sum for which the M.D. of Edinburgh can be obtained. This scheme includes some good points and many bad ones, which we will not at present consider in detail; the more so, as we have done so at length on former occasions (see THE LANCET, March 10th and 17th, 1883). We are looking at the scheme for the moment as a public proposal made by responsible and respectable bodies, and one to which the Medical Council will be asked to give its sanction. The Council should feel more than ever bound to see fair play to medical students and to the community at large in public medical arrangements. Should it sanction this scheme, no English student, however desirous—as, we think, all English-trained students should be—of obtaining a complete English qualification, will be able to do so under a cost of £36 15*s.* The Royal College of Physicians can now give a complete diploma in medicine and in surgery—and a respectable diploma too, one recognised by the State as a qualification in medicine, surgery, and midwifery—for the sum of £15 15*s.* It is somewhat strange that the College of Physicians should be willing to forego the rare power of complete diplomatisation conferred by ancient charter and amply recognised by modern usage. It is very doubtful whether in point of law it can do so. But it will be strange indeed if the Medical Council gives its sanction to a body discontinuing its legal and honourable function, in the exercise of which it has not been accused of performing slovenly work, and so compels the student to take two diplomas where one completely qualifies him for the duties of all branches of the profession. There is another aspect of this question. The Council has sanctioned a scheme for the co-operation of the three Scotch corporations, in which they agree to give three diplomas for £25. We say nothing here about the fact that the mere combination of corporations in the several divisions of the kingdom gives no guarantee of good work. The conjoint diplomas of the Scotch corporations have occasioned

Digitized by Google

more suspicion and scandal than any others. But what can the Medical Council hope for in the way of giving guarantees to England—which must really now look after itself—by sanctioning a scheme which will set two diplomas of England at £36 15*s.* against three diplomas of Scotland at £25? The Colleges of England should not drive men to the corporations of Scotland, and if they do so they should receive no sanction from the Medical Council.

LEAVING the personal issues involved in the regrettable dispute which has been raised by Mr. MUNDELLA'S equivocal mode of traversing Dr. CRICHTON BROWNE'S report on the subject of "over-pressure of work in public elementary schools," we turn to the main question: Is it, or is it not, the fact that over-pressure exists, and that it is doing mischief? The case seems to us to lie in a nutshell, and it would be difficult to cast the underlying hypothesis in a more terse form than that embodied in one of Dr. CRICHTON BROWNE'S concluding sentences. No one alleges, or for a moment supposes, that the Vice-President of the Council, or any influential member or official of the Educational Department, is either wilful or careless in the matter. It is simply a question of policy; and the most that need or can be justly said is said in these words: "It is quite possible that a scholar, whose body is twelve years old, but whose brain stopped growing at eight, might by his pleasing exterior and superficial sharpness impress the inspector with the idea that he is rather clever, while all the time he is childish, not to say babyish, in intellect, and ineducable beyond the first standard." If this be conceded, as we think it must be, then it follows that the inspector is not in a position to determine whether a particular pupil is or is not physically able to do the work required of him or her, and fit safely to be pressed through the educational curriculum. This seems to us to cover every contingency. It is not necessary to argue closely or warmly as to the question of experiences. It is conceivable that not a single case of injury may actually have occurred, and yet the system which makes a non-medical inspector—however humane and competent for his *proper* task—the judge of physico-mental fitness, whether of pupil or pupil teacher, must be indefensible. What are we doing? Simply this: applying a uniform pressure to a vast multitude of brains, some of which must, in the nature of things, be too weak or too ill-developed to bear the strain thrust upon them. It is a monstrous and inexplicable blunder this insistance on a level code of education for *all*. Why, even as regards the muscular and general organism of the soldier and the sailor a medical examination precedes the commencement of drill, and medical inspection from time to time keeps the question of health in view. Muscular weakness is not half so serious a bar to physical training as mind weakness is to intellectual exercise. How comes it to pass, then, that without any medical examination or supervision whatsoever the brains of a multitude of children, the majority of whom are under-bred and ill-fed, should be subjected to the same discipline and required to do the same task? It is not considered enough to know the age of a recruit for the army or navy; means are taken to ascertain whether his heart, lungs, and organs generally are healthy, and medical officers are specially appointed to examine him from time to time with a view to determine whether he is bearing the strain healthily; but no provision whatever is made for testing or watching the immature cerebral organs upon which the public pedagogue is not only left free, but required, to operate. The mere fact that this obvious measure of individual scrutiny, from the health point of view, is omitted puts the case for the Department out of court.

Dr. CRICHTON BROWNE insists that "in a great number of cases of dulness of intellect, a medical man could at once recognise the physical defects (which are often distinctive enough, although imperceptible except to the medical eye) which accompany mental weakness, and would support the judgment of the teachers; and in many cases of bodily disease and debility he could interfere to protect the children, even against the teachers, by preventing scholars who, although quick-witted and eager to learn, are certain to suffer in the process from being unduly pushed forward." The profession will endorse this statement as one of fact, and with that endorsement the dispute ought to end. Dr. CRICHTON BROWNE has undoubtedly proved his case. It is not to the point whether the victims are many or few; the system extant is radically bad; and that being so, the magnitude of the mischief wrought is of secondary importance. The blunder of striving to enforce a uniform code ought to be repaired without more ado. It may be strictly true, as Lord SHAFTESBURY has remarked, that "there does not live on the face of the earth a man who is more opposed to tyranny and oppression than Mr. MUNDELLA, or anyone more earnestly desirous of putting down all over-pressure as regards women and children." Then why, in the name of common sense, does not the Vice-President adopt the suggestion made to him, instead of fighting what must needs be a losing battle against his own moral and statesmanly consciousness of right?

Headaches, short-sightedness, neuralgia, and sleeplessness are not normal contingencies of youth, either for pupil teachers or children, yet it is a fact which Dr. CRICHTON BROWNE has demonstrated, and which men "engaged in the ordinary practice" among the humbler classes, and who, according to Mr. FITCH, are "able to know something of the children of the poor, their pursuits and their ailments," can substantiate, that these troubles—the direct fruits of over-pressure of work—largely prevail. Nothing can be gained by denying this fact, and certainly a lay inspector is not the person to contradict an able and experienced practitioner on the subject. Dr. CRICHTON BROWNE modestly says, "I cannot doubt that many of the facts which I have brought before you in this letter will be disputed, and that many of the principles which I have incidentally laid down will be challenged; but the former admit of verification, and in the latter I shall, I believe, have the support of the medical profession." We accept the facts and support the principles. If Mr. MUNDELLA is not satisfied with one of the best professional opinions obtainable, let him appoint a small commission of physicians and surgeons, men of mark, in whom he and the public will have confidence, but who are in no sort of way connected with the public service or the department, and let the issue be left in their hands. It is not for Mr. MUNDELLA and his lay inspector to impugn the judgment of a qualified physician. The presumption of

Digitized by Google

so doing does not beseem these gentlemen: it goes better with the crass heartlessness—to use no stronger epithet—of the school manager who, when a wearied mistress ventured to sit while teaching her class, ordered all chairs to be removed from the building! While the administration of our educational system rests in hands like these, there is little hope of success or safety in its operation. For the sake of children and teachers alike, the schools ought at once to be placed under medical supervision. In an able and interesting paper on "The Brain of the School Child," read before the Social Science Congress at Birmingham, Dr. FRANCIS WARNER has insisted on the urgency of the need which exists for medical inspection. We cordially endorse and support his argument. It is the cry of common sense. If the reasonable demand be not met fairly and fully, there cannot fail to be disappointment and regret when the inevitable issue of a mistaken and futile policy is fully worked out.

THE doctrine that phthisis is a communicable disease, to which the discovery of the tubercle bacillus gave some countenance, and the report last year of the Collective Investigation Committee of the British Medical Association tended in part to confirm, should, if it be a fact, find most support in the medical history of those places which are resorted to by invalids suffering from the disease. For thither there flock year by year numbers of tubercular individuals, mingling in social intercourse with, and inhabiting the houses of, the residents, many of whom have themselves chosen the place for their home on account of pulmonary affection or of an inherited tendency to it. Not very long ago Mr. THOMSON of Melbourne collected facts to show that tubercular phthisis had been in this way imported into Australia, and formulated thereon a "germ theory of phthisis" before KOCH'S discovery was made known. But it is reassuring to find that such an inference does not apply universally, and that, at least as regards Madeira, phthisis has not been disseminated in consequence of the annual influx of consumptives. Professor PAUL LANGERHANS, who is the author of a work upon Madeira, and has practised there for many years, contributes an article to VIRCHOW'S *Archiv*, based on a painstaking statistical inquiry which bears on the face of it evidence of accuracy, so far as it has been possible to attain it.

When Madeira was discovered by the Portuguese in 1419 it was uninhabited, and amongst the first settlers to join the Portuguese colony were families from France, Italy, and other European States. During the Napoleonic wars it was occupied by the English, who now form the major part of the inhabitants, of whom a small proportion are Germans, these residents being distinct from the original Portuguese element, who form the industrial class. For nearly a century the island has been annually resorted to by invalids to the number of about three or four hundred, who, together with an equal proportion of healthy visitors, add largely to the population during the winter months. The largest number of these are English, some remaining for several years, and others taking up their abode permanently. Since the failure of the wine trade the number of residents has fallen off—viz., from about 320 in 1836 to 270 at the present time, of whom 250 are English. It is plain that the residents must be brought into contact with the annual influx of visitors, who occupy about 100 houses in winter and 50 in summer, so that with the lapse of time there is scarcely a house that has not received the phthisical at one period or another.

The material for an inquiry into the influence exerted by this phthisical environment is afforded by registration records, which Dr. LANGERHANS has analysed. These records date from the year 1836, when there were 321 residents, and among these he has traced the subsequent history of 267, of which number 210 were healthy subjects and free from any inherited phthisical taint, the remaining 57 being individuals who had come for their health or who had inherited a disposition to phthisis. Of the 210 healthy people (34 being then under the age of ten years), 78 have died in Madeira since 1836, at an average age of sixty years. Four of these died from phthisis, two contracting the disease apparently abroad and returning to Madeira to die, the third dying after a slow illness at the age of thirty-eight, and the fourth at the age of fifty-five from acute pneumonic phthisis. There have also died after leaving Madeira 46, none from phthisis. There still survive 86 of these people, at an average age of sixty-two, but only 24 now reside in Madeira. There is no case of phthisis known amongst these survivors. Turning now to the 57 who in 1836 were affected with lung disease or disposed to it, there have since died 35, 9 being from phthisis, but only 2 of these deaths occurred in the island. Of the survivors, 9 remain in Madeira at an average age of sixty-nine, and 13 are living elsewhere, one only, a woman fifty-one years of age, presenting indications of phthisis. The writer next inquires into the fate of those people who have settled in the island since 1836; and dealing only with those who have dwelt there for more than twenty years, he has compiled a table including 115 persons, 83 of whom were of healthy and 32 of unhealthy stock. Amongst the 31 deaths that have occurred in the former group there has not been one case of phthisis, nor is there any phthisical person among the survivors. Of the 32 who came phthisically disposed, 17 are dead, including 12 cases of phthisis. Again, he finds that 253 children have been born to the 382 (residents in 1836 and subsequent immigrants) between 1836 and 1884, 147 being of healthy and 106 of tainted parentage. Amongst the former there have been 28 deaths, one from phthisis at the age of thirty-seven, after alcoholic excess in England; whilst of the latter 23 have died, 8 from phthisis; and 8 phthisical individuals survive in this group of 106 children, at an average age of thirty-six years.

The sum of these observations, which are far more fully elaborated in the article, is that between 1836 and 1884 Madeira contained 835 residents, of whom 440 were of healthy and 195 of presumably tainted stock. Tracing the subsequent history of these, it appears that of the 440 there have died 208, only 5 from phthisis during this long period, and 2 of these dying elsewhere than in Madeira. Not one of the 237 survivors exhibits signs of lung disease. If this be true, it is a striking fact, for it shows that in spite of conditions most favourable to infection, phthisis barely ever occurs amongst those free from inherited taint. Indeed, the proportion of the phthisical is below the average of other countries, and implies that residence in Madeira affords immunity against the onset of the disease, even under most

Digitized by Google

unfavourable conditions. It is of course otherwise with the 195 who have either arrived in the island ill, or have derived a tendency to the disease from their parents; and yet the numbers show that the disease must have been arrested in many; for although 29 of the 75 deaths in this group have been from phthisis, there are but 12 of the 120 survivors who show evidence of the disease. Dr. LANGERHANS does not rest here, but in a further analysis he separates the members of each of the four generations from 1836 onwards. The numbers are too few to admit of generalisation; but they tend to show that phthisis appears in the later generations, to become milder in type, and slower in its evolution.

Dr. LANGERHANS thinks that these facts, and especially the fact that since 1836 almost the only individuals to fall ill of phthisis in the colony have been those in whom heredity could be traced, point to the very great importance of inheritance in the etiology of phthisis. They seem to be wholly opposed to the notion that phthisis is an infective disease, and rather assign it a place with such affections as cancer or hæmophilia. As showing the influence of heredity, he gives the genealogy of eight families, whereby it is seen that the tendency to phthisis may remain latent for one generation, to be manifested in the next; and it also appears as if special forms of the disease were transmitted. Nor does his inquiry, necessarily limited as it is, lead him to endorse the popular belief that children born of parents who have inherited phthisis, but who do not manifest the disease until a later period, are any the less liable to become its subjects than are those who are procreated after the disease is manifest. Indeed, the liability may be even greater in the earlier than in the later born progeny. These are suggestive points; and we wish that the family practitioners of our country, where phthisis claims so many victims, would compile similar genealogies for the benefit of science. It would not be difficult in many cases to so trace the medical history of a phthisical family through several generations, and the result of such an inquiry, if conducted on all sides, might serve a very useful purpose.

A SERIES of experiments of much interest has been performed on the supra-renal body during the past year by M. TIZZONI. In order to avoid unnecessary sacrifice of life, the author studied the best methods of removing the supra-renal capsules without damage to the surrounding structures and with the infliction of the least possible injury to the system at large. After having made a small incision in the lumbar region at the level of the adrenal body, the parenchyma of the capsule was lacerated and its ablation practised, strict antiseptic precautions being observed. On the right side the neighbouring vena cava inferior rendered the operation of extirpation difficult. For his experiments TIZZONI generally made use of rabbits weighing only about a kilogramme each, because in this circumstance the muscular mass of the lumbar region was but little developed, and so the operation was facilitated. When the animals succumbed as the result of the operative procedure, death was not due to the nervous accidents signalised by BROWN-SÉQUARD, but was caused by subcutaneous and intermuscular suppuration infiltrating the neighbourhood of the wound. The majority of the animals which exhibited contracture of one or other of the front or hind limbs recovered, and it was only rarely that paralysis and death followed the appearance of the spastic contraction. The necropsy revealed in such cases the presence of an exudation about the meninges of the spinal cord and a softening of the spinal marrow without any demonstrable direct connexion of the lesion of the supra-renal capsule with that of the nervous centres. Outside these complications—which may be regarded as quite exceptional—the operation was generally followed by no grave accidents; the animal, if the etherisation were not too powerful, gave signs of pain only when the adrenal capsule was seized and lacerated. If this body, instead of being completely removed, were allowed to remain in the cavity of the abdomen (of course, after laceration of the capsule), the healing was much more rapidly effected; and if, some days later, the animal were killed, not a trace of the lacerated parenchyma of the suprarenal capsule could be detected; complete absorption of the essential elements appeared to have taken place. Then, according to TIZZONI, the suprarenal body is absorbed without giving rise to any phenomena such as might be interpreted to be of the nature of blood-poisoning, so that the adrenal capsule contains no organic poison; and if by treating the organ with various chemical reagents a poison be obtained, one may affirm that it is not produced during life, and consequently the poison must be due to cadaveric decomposition. A certain time after the extirpation of the capsule there commences to appear a brownish discoloration of the nose, as if the animal had been plunged in charcoal powder after having drunk some liquid. Some small blackish linear markings also may be found scattered here and there, over the mouth and nasal fossæ. The mucous membranes of these regions seem at first to be intact, but at the end of some days they become dotted with minute spots of the colour of tobacco; the minute areas become circular as they enlarge, and by coalescence a bronzed surface of considerable extent and of a uniform tint is formed, and reaches its maximum intensity about the sixtieth day after the operation of removal or laceration of the suprarenal capsule. A remarkable circumstance is mentioned by the Italian observer, which is to the effect that the destruction of one capsule only brings about unilateral pigmentation of that side of the body on which the operation was performed. If, however, the median line of the body were trespassed upon, the pigmentation extended to the whole of the surface of the body. (The text from which this report is taken leaves it doubtful by what the median line of the body was to be trespassed upon. We take it that should the pigmentation proceed beyond the mesial line then the discoloration would be universal.) White rabbits did not present any of the pigmentary phenomena.

From a histological point of view the following observations were made. When the coagulum of blood and the parenchyma of the lacerated organ had been resorbed, the fibrous envelope of the capsule was found to be filled with a connective tissue of new formation, together with large granular cells like those which are found in white softening of the brain; giant cells which had undergone caseous degeneration were also to be seen. The last fact would seem to negative NOTHNAGEL'S opinion that chronic caseous inflammation of the adrenal body was always of a

Digitized by Google

tubercular nature. These giant cells were produced in the same way as those which develop as the result of irritation of serous membranes by a foreign body. Another observation was made by TIZZONI, which appears to be extraordinary, to say the least of it. The various elements of the suprarenal capsule in the rabbit may be "reconstructed." This fact is alleged to have been observed 144 days after the almost total destruction of the suprarenal body in a rabbit. The size, colour, and structure of the organ were normal in another rabbit twenty-six days after the operation, presumably, of free laceration. At the autopsy a small nodule exhibiting active new formation of suprarenal parenchyma was also discovered. A fine interlacement of filaments of the great sympathetic cord with numerous ganglion cells and gangliform swellings had developed and covered the cortical substance of the adrenal gland of the animal last referred to. The Italian pathologist does not speculate on the mode of production of the bronzing which he observed. Many of the statements made by him require careful consideration at the hands of other experimental pathologists, but as opening up afresh the relations of the adrenal body to the system at large the results of TIZZONI'S experiments must be admitted to be of decided value.

THIS unsavoury but essentially important subject is again to the front. The only marvel is that it should ever be lost sight of even for a moment. The correspondence which is going on in *The Times* has not, so far, been characterised by the making of any new disclosure. It is perfectly well known to all who have investigated the subject of house-drainage and sewerage, that the pipes designed to convey the soil and waste-water from house-closets and sinks, and which often run under kitchens and between floors without isolation—in any true sense of the term—are not uncommonly simply placed together without being properly connected. We recently heard of an instance in which the workmen employed on the outside drain did their work well enough, and those engaged on the house drains performed their task with commendable skill and integrity; but no one seems to have been appointed to connect the two systems, so that the contents of the house-drains were discharged into the earth of the basement under the kitchen and formed a large cesspool, while the free end of the outside drain or pipe ventilated the sewer into the premises, and delivered sewer-gas without let or hindrance. The work was in this case well done, as far as it went, only it did not go quite far enough. The omission to make good the joints of drain-pipes is a quite ordinary piece of negligence. The correspondents in *The Times* insist that house drains should be periodically tested by filling them with water, and then noticing whether, when the proper outlets are stopped, the water level sinks; because if it does there must be an improper outlet—in short, a leak—somewhere. This is all very well as a rough test; but it is not enough to rely upon as ground for a guarantee of safety from sewer-gas. We know perfectly well that gas will escape from an opening which is not large enough to allow any perceptible escape of water! Many a crack or opening, which would suffice to fill a house with sewer gas would not allow so much water to escape as to make any notable difference in the level, even though the drains were charged for some hours. The fact is no test will suffice to make this matter safe, and safety ought not to be looked for solely in the integrity of the work done, important as this must be. Perfect "disconnection" should be insisted upon, so that whatever is wrong in a house must needs be of the householder's own making. It is not the soil from the house that does harm, but the sewer gas entering the house-drain from outside. Of course, if the inside work be bad there may be an escape of the contents of the house-drain into the earth of the basement, as in the case just mentioned; but this is a contingency well within control. The great evil against which those who would have healthy homes have to contend is the effect of blundering on the part of sanitary engineers and drain-makers generally. They *will* make openings "for the inlet of fresh air" at the lower levels, forgetful or ignorant of the fact that where air can get in gas can and will escape! It ought to be made imperative on every householder to erect a ventilating shaft immediately outside his house system, and to carry the same above the roof of his house away from his chimneys. No ventilating pipe or grating should be allowed to open on the lower levels. It is all nonsense about letting fresh air into the drains from the ground levels. The aim and scheme should be to afford such vent for the contained air, or gas, of the outside drain, at a high level as shall prevent the comparatively warm house-drains and pipes from sucking the gas into the house. All the year round a house and its pipes are warmer than the sewer, and when the fires are lighted they are very much warmer. As a natural physical consequence the house is always drawing air from the sewer; and the only proper and safe precaution is to place a ventilating shaft immediately *outside the house-system*, so that there shall be no pressure from without inwards to create a *vis a tergo* supplementary to the *vis a fronte* created by the higher temperature of the house-drains. We know this will seem strange doctrine, but we are convinced it is sound, and that it ought to be generally understood and acted upon by householders who would be safe.

Annotations.

"Ne quid nimis."

OUT-PATIENT DEPARTMENTS AT LARGE HOSPITALS.

THE conditions under which the physicians and surgeons to the out-patients at our large hospitals have to work are anything but hygienic in the more limited sense of the term. The crowded waiting-rooms, which frequently discharge their loaded and poisonous atmosphere into the very working-rooms and up the very nostrils of the physicians, are certainly not the kind of apartments favourable to the best intellectual work. We have no desire to find fault with the authorities of any of our hospitals—their task is hard enough in many ways; but we do hope that the condition of their out-patient departments will receive the consideration they so much need. We are fully aware that some of the hospitals which are most numerously attended are amply provided for in respect of the distribution and management of their out-patient arrangements; but we should like to see this provision more general at all the hospitals. Really the matter is one of serious importance. The out-patient department falls to the lot of the junior members of a staff who have before them many years

Digitized by Google

of labour and weary waiting. For them it is essential that the bodily vigour and intellectual activity which they possess should not be consumed before the time comes for their term of service in the wards. Anyone who will take the trouble to spend one afternoon in assiduously doing the duty or following the steps of the out-patient medical officer will soon be brought to a sense of the weariness and hard work which such physician or surgeon must undergo. And when we remember that this task has to be performed thrice or oftener a week all the year round, it will be readily conceded that the labour is one which calls for comfortable quarters and hygienic surroundings. Every man has, or ought to have, a reserve of force; and this reserve ought never to be drawn on. No physician or surgeon should be expected to do more than two hours' work in the out-patient department; four or more hours spent in the out-patient rooms severely tax the reserve force of most physicians and surgeons, and make it correspondingly difficult for the reserve power to be recouped. Indeed, this continued over-work is a too frequent cause of the premature breakdown of some of the junior medical men attached to hospitals; and usually it is precisely these who are least able to obtain the needed annual holiday; they have to do their own work during the session and that of their seniors in addition during the vacation. It is time that the offensiveness, uncleanliness, and overcrowding of our out-patient departments should by necessary alterations be reduced to the minimum.

THE LONDON WATER-SUPPLY.

WHETHER the London water-supply is good or bad is a moot point now as it was a dozen years ago. Dr. Frankland still thinks it unsatisfactory; while Messrs. Crookes, Odling, and Tidy, who represent the water companies, seem to consider it as practically perfect. Some natural bias, no doubt, exists on both sides; for each of the eminent chemists concerned has held and fought for his opinion so long that it is impossible to suppose him an absolutely impartial witness. Thanks to external pressure, and by no means to their own spontaneous action, the great London water companies have greatly improved their supply of late years. They have long been debarred from the use of tidal water, and have been compelled to filter all the water drawn from rivers and store it in covered reservoirs. In the last few years the filtration has been greatly improved, and the water delivered to the consumers is now, as a rule, free from visible suspended matters and of fair organic purity. Probably sand filtration is now doing its utmost in the purification of the contaminated waters of the Thames and Lea. The question is, therefore, whether we ought now to be satisfied with our water-supply—to "rest and be thankful." We are compelled to believe that we ought not; for even if we were to accept all the statements of the water companies as to the present purity of their supply, we could not forget that the source of that supply is a polluted one, and that in addition to the ordinary sewage pollution, representing the excreta of an immense number of persons, there is at all times the risk of an accidental and far more dangerous pollution in the neighbourhood of the companies' intake. The Thames, for example, is in summer a crowded thoroughfare. Many people bathe in it; dead dogs are by no means infrequent; barges, house-boats, steamers, and smaller craft throng its waters; and it is certain that foul matters do, from time to time, find their way into the water from these, as we can testify from personal knowledge. A single case of cholera or choleraic diarrhœa occurring in a barge might obviously lead to most disastrous results; for the filter-bed would be a poor protection against the subtle poison, and the chances are that an outbreak occasioned in this way would never be traced to its source.

THE EPIDEMIC AT KIDDERMINSTER.

THE outbreak of enteric fever at Kidderminster has assumed very serious proportions, and although its incidence is mainly on some of the worst parts of the town, yet all classes are suffering, and at least one of the principal medical practitioners has been attacked. Dr. Parsons, of the Local Government Board, is investigating the causes of the epidemic, and he has already conferred both with the sanitary authority and a number of the medical men in the town. The outbreak, as we have already explained, had at the onset much of the appearance of having been produced by water pollution, and the fact that one of the wells of the public service is in such relationship to the area of the sewage pumping works that its use has now been abandoned, gives some additional colour to this view. The condition of the sewers, if correctly described in the local press, is precisely such as to favour the spread of diseases like enteric fever, for it appears that, instead of allowing the sewage to flow away, certain catch-pits have been constructed in the line of the sewers, and that in these solids are retained. Whether the statement be true or not as regards Kidderminster, it is certain that this system is at times adopted, and any more dangerous or offensive contrivance it is difficult to conceive. Such pits are cesspools, and cesspools have no *raison d'être* in a system of sewers. Sewers are designed to carry away sewage in the most rapid manner practicable, not to retain its most injurious constituents. It is to be feared that the epidemic at Kidderminster has already attacked some 500 persons, and we are now arriving at the stage of the disease amongst those first attacked when fatal results most commonly ensue. We sincerely trust the mortality will be small, and that the cause will turn out to be one which can be expeditiously rectified.

URÆMIA.

THE pathology of uræmia reminds one of attempts to thread a needle in darkness, the distance of the point of the thread from the eye of the needle being very difficult to determine. One year we are informed on good authority that urea may be injected into the system without serious results, and the next year the direct opposite is affirmed. This is but one aspect of this many-sided subject. The chief dispute in the pathology of uræmia is as to the nature of the toxic agent. MM. Gréhant and Quinquaud have returned once more to the question, and in an experimental method. Subcutaneous injections of aqueous solutions of pure urea have been employed in gradually increasing quantities on frogs, guinea-pigs, rabbits, pigeons, and dogs. The result was constant for the different kinds of animals, and consisted in a more or less rapid death from tetanic convulsions, similar to those produced by strychnia. The most numerous experiments were performed on dogs. The toxic dose of urea in the blood was fixed with exactitude, and the influence of urea on muscular contractility was studied. Death always ensued when a dog received into its system 0 grammes of urea for every kilogramme of body weight, or in other words when a hundredth part of the body weight of urea was injected. The proportion of urea in the blood, as estimated just before or after death, was ·6 gramme for every 100 grammes of blood, and this relative proportion obtained in all the other animals employed. In a case of anuria in a man the proportion was ·410 per 100 grammes, and in another case of retention of urine ·278; in a case of interstitial nephritis, the patient suffering from uræmic dyspnœa, it was ·210, and in a case of uræmic coma ·215. Under the circumstances of the experiments all the tissues of the animals were impregnated with urea, so that 100 grammes of blood yielded 613 milligrammes of urea; 100 grammes of liver, 589

Digitized by Google

milligrammes; 100 grammes of cardiac tissue, 311 milligrammes; 100 grammes of spleen, 662 milligrammes. The observers always noticed that the urea injected under the skin was never completely absorbed, even at the time of death, though death might have been delayed for ten hours. By exposing the sciatic nerve and displaying the calf muscles, to the cut tendo Achillis of which a dynamometer was connected, the authors decided that uræmia does not increase or diminish muscular contractility. The blood of the dead animals, when submitted to distillation at a temperature of 40° C. *in vacuo*, furnished a liquid absolutely free from ammonia; the conclusion drawn from this experiment is that urea does not act as ammonic carbonate.

FRIENDLY SOCIETIES' PROVIDENT MEDICAL INSTITUTIONS.

OUR readers are well aware that in some towns the old and friendly institution of the "club doctor" has been threatened with overthrow by the wholesale amalgamation of Friendly Societies into one huge Provident Medical Institution, to be served medically by one doctor, with perhaps an assistant. Everything in this institution was to be on a huge scale, except the remuneration and the liberty of the medical man. His work was to be that of several medical men; he was not to be allowed to do it in his own way, but on a system of iron rules, and his salary was to be as small as his liberty. Such arrangements have never had our approval. They did not appear to us likely to secure the best results to the members of sick societies and their friends; they treat thousands of human beings as if they were without choice and preference in regard to medical practitioners; they presume on the eagerness of young medical men "wanting a start" and tempted to overlook what is due to the profession and to seniors who have worked other provident arrangements patiently and conscientiously, and by so doing have formed extensive medical relations with the working classes which are most beneficial and creditable. Moreover, such institutions seem to be manipulated by small committees or caucuses, without reference to the wishes of the members, and with such scanty appreciation of the respect due to professional men, that even the youngest and most eager of these must soon find that in serving them he is serving a hard master. We have on various occasions expressed these views, but never with any but the most respectful feelings to the members of friendly societies, who deserve all praise for their provident intentions and for their efforts to put the medical attendance of the working classes on an independent footing. Our objections meet with striking illustration and confirmation in a pamphlet sent us by Dr. Maunsell, containing letters published first in the *Bath Argus*, and setting forth the arbitrary way in which the Committee of the Bath Amalgamated Friendly Societies' Provident Medical Institute have called for his resignation, without deigning to give any reasons. The only reason seems to be that he appears to have been overcome with doubts as to the perfectly satisfactory working of such institutes, and to have been bold enough to suggest changes for "placing them on a basis that will enable medical men to accept and retain the appointments." He has published letters from gentlemen holding the existing appointments, some of which are no doubt aggravating to committees of such institutes as the B.A.F.S.P.M.I. One honorary surgeon of the Bath Institute, Mr. Hoblyn, says: "I know very little of their rules, or how they intend to work, but from all I have as yet made out I do not see how any man is to do all the work, and I do not suppose that any one can retain the appointment longer than six months. For my own part, I do not, as my age, object to be tied down to time in any manner. I have no objection, myself, to be called consulting surgeon, with any definite duties to perform, for a guinea a visit." A medical officer of such an institution writes: "I am working beyond powers of endurance." Another says: "I 'put up' with the work for three years, during which time I suffered enough insult and annoyance to last a moderate lifetime, had it not been condensed into three years. I resigned in disgust because the committee was powerless to enforce their own rules, the members of which body were quite at the mercy of their various clubs, and although quite ready to make rules, only required me to keep them, and always interpreted them as the members of the Association wished. Professionally, the rank and file of the medical profession here put me 'in Coventry;' the consulting men did not actually refuse to meet me, but practically I was outside the profession." The Bath Institute should initiate a testimonial to Dr. Maunsell instead of dismissing him. Let the working classes take the whole profession a little more into their respect and consideration, and they will find that they have no better friends in the dark days of trouble and sickness than the tried practitioners by whom they are surrounded.

COMMITTAL AND DISCHARGE OF DR. WOLFF.

OUR readers will remember that during the conflict of opinions that has raged at the Diamond Fields respecting the nature of the disease which has proved so disastrous in its results, Dr. Wolff has been a persistent opponent of the theory which supposes the epidemic to be one of small-pox. It was with deep regret that we heard of the committal of Dr. Wolff on the charge of "culpable homicide" for having, as alleged, allowed a woman to be exposed to the contagion of small-pox, not only without warning her of the danger, but with the positive assertion that neither infection nor contagion was to be feared. According to the sworn testimony of the witnesses, Dr. Wolff attended a patient who was suffering from an eruptive fever which proved fatal. The woman who laid out the deceased sickened twelve days afterwards and died, from the effects of what Dr. Grimmer, who was called in to see her, declared was no other than small-pox. It was of having indirectly caused her death that Dr. Wolff was accused. For obvious reasons we did not discuss the merits of the case at an earlier date, although we were then, as now, convinced that before a grand jury found a true bill they would have to satisfy themselves (1) that Dr. Wolff was *primâ facie* answerable for having contributed to the death through wilful and culpable negligence; (2) that he had contravened the 35th section of the Public Health Act, which orders that a medical practitioner shall inform a householder as early as possible of a case of small-pox, or a disease declared by the governor to be infectious, having occurred in his house; (3) that even supposing the deceased to have succumbed to small-pox, the infection was, without reasonable doubt, derived from the source set forth in the indictment. Drs. Sauer, Grimmer, and Smith, who examined the body after its exhumation, were agreed that the death was due to confluent small-pox, and the two former deposed to that effect. Dr. L. S. Jameson, who was called for the defence, is reported to have said that the epidemic is not one of small-pox, and that it is not contagious, and is probably propagated by the soil. Notwithstanding we are entirely opposed to this view of Drs. Jameson and Wolff, we give them the credit of being honestly persuaded of its truth, and it would be unjust to hold Dr. Wolff responsible for the consequences of error of judgment. As he stated in his defence, if he believed the disease was not small-pox he could not be expected to notify that it was. The present epidemic has not been declared by the governor to be small-pox, and the only disease [illegible] small-pox specified as infectious in the section of the Act

Digitized by Google

referred to is syphilis. On these grounds alone, as it seems to us, the prosecution must have failed. Although Dr. Wolff was committed for trial by the local magistrate, the public prosecutor refused to take up the case against him, and a warrant was made out for his discharge. Whilst congratulating Dr. Wolff on his deliverance, we take the opportunity of entreating him and Dr. Jameson to once more weigh the evidence as to the character of the scourge with which the Diamond Fields are visited, and see if they cannot adopt the almost universally accepted belief that they are confronted with what is commonly known as small-pox. As to the executive authorities, we urge upon them the taking of such steps as will render the recurrence of the unhappy affair related above an impossibility.

THE OUTBREAK OF ENTERIC FEVER IN THE GLASGOW HOSPITALS.

DR. RUSSELL, medical officer of health for Glasgow city, has presented to the Health Committee a long and elaborate report on the outbreak of enteric fever in the Glasgow Hospitals. He describes the rise of the epidemic in the Western Infirmary towards the end of August last. The disease was not confined to patients, but attacked the nurses and attendants, and was not limited to any ward or department. In the history of the hospital only one case of enteric fever had ever originated in the building, and that was some years ago, in the person of one of the nursing staff who was in attendance on an isolated patient admitted to the house. As to the cause of the outbreak, water, says Dr. Russell, may always be set aside as an epidemic agent. The fact of cases occurring simultaneously also in the Royal Infirmary and the Belvidere Hospital, institutions deriving a portion of their milk-supply from the same farm, however, at once directed suspicion to the latter as the source of the mischief. On close investigation this suspicion was confirmed. On the farm in question several cattle had suffered from disease, arising, in the opinion of a local veterinary surgeon, from drinking foul water. An analysis made by Dr. John Clark, city analyst, showed the water of the well used on the farm to be grossly contaminated with the products of sewage, indicating that the soil in the vicinity of the well was saturated with sewage matters. There was evidence, moreover, to show that enteric fever was produced in consumers of milk from the farm who were not inmates of either of the hospitals. The report gives in detail an account of the main features of the outbreak in the three institutions up to September 17th. In the Western Infirmary forty-four cases in all occurred; in the Belvidere Hospital thirty-one persons were affected; and in the Royal Infirmary the sufferers numbered twenty-nine. Dr. Russell concludes his report with a severe animadversion on the supineness of the local authority in allowing the district in which the farm is situated to remain in the bad sanitary condition in which it has been long known to exist, and after the attention of the authority had been repeatedly called to the matter.

RHEUMATIC PERIOSTITIS.

A DISCUSSION took place at the recent meeting of the French Association for the Advancement of Science, held at Blois, on a communication by M. Verneuil, entitled "Ephemeral Rheumatic Periostitis," an affection which has not attracted a large share of attention from writers on medicine. It is described by M. Verneuil as appearing in the form of a hard swelling, becoming softer after the lapse of a certain time. Fluctuation, which is sometimes present, leads to the suggestion of pus; but this phenomenon disappears and the swelling subsides. There is no hyperplasia like that seen in ordinary surgical periostitis, no fever, and no alteration in the colour of the skin. In some places the affection spontaneously disappears, in others the swelling first diminishes and then increases in size; there seems to be a congestive element in the swelling, for "when the patient took cold" one of the swellings on the face became double its former size. In none of the cases was there evidence of antecedent syphilis, though the arthritic diathesis was well represented. Many observers who spoke on M. Verneuil's paper had witnessed similar affections. On purely theoretical grounds there does not appear to be any argument against the occurrence of rheumatic nodes or periostitis. We have nothing to do on this occasion with the "subcutaneous rheumatic nodules" so well worked at by Drs. Barlow, Warner, and others. We may also take it for granted that the periostitis was not confounded with the nodose erythemata of rheumatism, where the skin is the site involved. Physicians of large experience cannot fail to have seen examples of periostitis occurring in rheumatic cases. We have no wish to beg the question; and it is right that the whole evidence on which the rheumatic origin of such cases of periostitis exists should be placed clearly before us. In our experience there has been distinct affection of joints of typical rheumatic nature with sweating, and in some instances heart affection and fugitive erythemata with fever of moderate degree. In one case which we recall, the tonsil was also inflamed, whilst there was mitral disease of some standing, distinct affection of both knees and the right wrist, with periostitis of the lower third of the inner side of the right tibia, occurring in a man aged twenty-four, in whom no evidence of syphilis could be elicited, and who was not suffering from gonorrhœa. We should be chary of admitting the presence of rheumatic periostitis when no other "rheumatic" manifestations are to be found. We may also state that in our experience nothing we should call fluctuation was detected. The subject is one well worthy of extensive investigation, and would undoubtedly add to our knowledge of that most protean and most ill-understood affection—rheumatism.

DAIRY FARMS AND SCHOOLS.

WE have received the prospectus of the Southern Counties Dairy Farm Association, Limited, which has been started with the double object of providing farm and dairy produce on sanitary and scientific principles, and of establishing a school at which all that pertains to dairy farming can be practically taught. On a former occasion we wrote at some length on the advantages that would accrue from the adoption of such a line of action. We fear that English dairy farming generally is carried on without due regard to many points essential to the success of an enterprise which, apart from the question of monetary remuneration, has an important bearing on the health and comfort of the community. It is an undoubted fact that the "milk-producing power" of cows is largely under the control of those who have charge of them. The selection of animals suited to certain pastures is of primary importance, but of greater moment still is the development of the resources of grazing and arable land by natural and artificial means. Proper drainage and water-supply need only passing mention. A large field is open for improvement as regards the proper cultivation of the soil, including its preparation for those kinds of pasturage best adapted to thrive upon it. There is no reason whatever why every farmer and grazier should not be able to avail himself of the knowledge which the agricultural chemist and the sanitary engineer are able to give. In the present depressed condition of trade in land there are few, we fear, who will be induced to try what appear to them as new-fangled ideas of getting more for their money and labour than they have hitherto succeeded in doing, unless tangible

Digitized by Google

results are brought under their notice at some one else's expense. For this reason we trust that associations similar to that above referred to will be multiplied and worked with rigorous economy yet generous treatment. The allotment of "broad acres" into small farms is preferable to the system of extensive "runs," both for the prevention and arrest of diseases that decimate our herds and flocks. This holds good alike as concerns serious epidemic disorders and certain diseases dependent on accident, overcrowding, or the spread and development of entozoa. "Sturdy," or "the gid" in sheep—e.g., which is due to the presence in the brain of cœnurus cerebralis, the larval or hydatid form of tænia cœnurus of the dog, is not nearly so common in enclosed pastures as in unenclosed, where the sheep are herded by dogs. There are many other considerations which might be urged in favour of a more enlightened system of dairy farming than at present obtains, but enough has been written to justify the attempts that are here and there being made to make us at least equal in this matter to our Continental neighbours.

"TEXAN FEVER."

THE stipendiary magistrate at the Birkenhead Police Court had before him on Sept. 17th a very important case for decision. The meat inspector for the Corporation applied for an order to destroy the carcase of an animal belonging to Messrs. Nelson, cattle importers, which animal, it was alleged, had died from the effects of a disease known as "Texan fever." The 117th Section of the Public Health Act of 1875 states that if a magistrate is convinced that the meat is diseased he shall condemn it, even if he is not certain that it is unfit for human food. The meat inspector deposed that the carcase of the beast recently killed was deeply bile-stained and was of a dirty yellow colour, that in the fourth compartment of the stomach (abomasum) were a number of erosions and ulcers, that the spleen, which was congested, weighed 9½ lb., the normal weight being about 2 lb. (Armatage gives 2 to 3 lb.) The liver weighed 24½ lb., whereas it should only have weighed about 15 lb. The kidneys weighed 1½ lb. more than normal. He was of opinion that the disease was "Texan fever," which he said was the twin sister of splenic fever. Mr. Moore, V.S., Privy Council Inspector of Cattle, corroborated the inspector's evidence as to the nature of the complaint the animal suffered from. He stated that "Texan fever" was conveyed from animal to animal by direct contagion, and that it took from ten to forty-two days for its full development. Drs. Vacher, Braidwood, and Craigmile gave similar testimony. For the defence, Mr. Wylde, Chief Inspector of Meat for the City of London; Mr. Holman, V.S., Inspector for the Privy Council at Deptford; Drs. Imlach and Paul, of Liverpool; Professor Williams, of the New Veterinary College, Edinburgh; and Inspector Luyd, of Liverpool, were called. The magistrate, puzzled, as well he might be, by the contradictory nature of the evidence, decided the case on the grounds that from his own inspection he could not say the meat was unfit for human food; therefore he could not say it was diseased, and consequently he refused to condemn it. The logic of this argument is a little confused, as it seems to us, yet under the circumstances we cannot impugn the magistrate's decision. Whether there is such a disease as "Texan fever" or not, and whether the animal in question died from it or not, we hold that a very strong case was made out by the applicants. It is not usual for "coarse feeding" nor a sea voyage to cause ulceration of the stomach and enlargement of the liver and spleen to the extent described in this instance. A much wider issue was involved than the mere condemnation of a carcase of beef. If "Texan fever" is a blood disease at all resembling splenic fever, the most rigorous measures ought to be adopted to prevent its diffusion. It is but just to add, that out of 540 animals carried by the same vessel, only one was affected in the manner described. In the event of a like case occurring in the future, we hope that it will receive a full and impartial scientific investigation, so that this vexed question concerning a disputed disease may be finally set at rest.

SUCCESSFUL NEPHRECTOMY FOR CALCULOUS PYELITIS.

La Gazzetta degli Ospitali (Aug. 31st) contains a report by Dr. A. Salomoni of a case in which Professor E. Bottini successfully removed the kidney. The operation was performed at Milan, on the 8th of June last. The patient, Annibale M——, aged twenty-seven, had had two calculi removed by lateral lithotomy fifteen years previously. Three years after that operation an abscess formed in the right iliac fossa. It opened spontaneously, and after a few months reappeared in the lumbar region, when it was opened with caustic potass. A permanent fistula resulted, and proved intractable to all local and constitutional treatment. The patient lying on the left side, under chloroform, Professor Bottini, under strict antiseptic precautions, made a vertical incision through the whole ilio-costal space, three inches outside the quadratus lumborum. The kidney having been isolated, the renal artery was secured in one ligature, the vein and ureter in another. The space having been well cleared and all bleeding stopped, a drainage-tube, about one-third of an inch in diameter, was introduced. The walls of the fistula were excised, and the wound united by one deep metallic suture and eight superficial silk ones. The operation lasted a little over an hour. The antiseptic dressing was renewed daily, the metallic suture was removed on the third, and the silk ones on the fourth day, when the drainage-tube was shortened. It was withdrawn on the eighteenth day. Progress was uninterrupted. The highest temperature, 37·8° C, was reached the second day; urine in normal quantity and without deposit was passed without pain or trouble. The patient left his bed on the sixth, and went home the eighteenth day, when only a slight sinus remained, about an inch deep. The extirpated kidney weighed forty-eight grammes, and measured vertically six centimetres, four across, and two anteroposteriorly. Its consistence was greater than normal; colour greyish. On section the upper three-fourths consisted of fibro-cellular tissue, the lower fourth of renal parenchyma, altered, with the pyramids in process of disappearance. The fistula led into the pelvis of the kidney, which was dilated, with thickened and suppurating walls, and contained, besides some uric-acid sand, two small calculi about the size and shape of grains of barley.

SULPHUR FIRES IN CHOLERA EPIDEMICS.

IN the autumn of 1872, when sanitary officer at the Sonepore Fair and during the height of the pilgrimage, when the people thronged in thousands to the bathing ghats, Deputy Surgeon-General Tuson first used sulphur fires as a prophylactic measure against cholera. These fires were made at fifty yards apart and kept alight during the whole time that the fair was at its height. Not a single case of cholera occurred; a remarkable circumstance, since cholera had generally broken out at previous fairs. A similar good result was obtained at Dinapore, where cholera was actually prevailing. In the pamphlet on this subject, which is published by W. H. Allen and Co., Waterloo-place, Dr. Tuson has adduced certain facts and arguments in support of the contention that sulphur fires are efficacious in epidemics of cholera. The basis of his explanation of their efficacy is the germ theory of the disease.

CARDIOPATHY OF NEURAL ORIGIN.

THE field of nervous disease is a field for all. There seems to be nothing in the disorders of the body which may not emanate from disorder of the nervous system. M. Teissier of Lyons read a paper at the Congress of the Association for the Advancement of Science, held at Blois, on "Cardiopathies d'Origine Spinale." He said that transitory cardiac affections due to nerve disturbance were by no means rare; Graves' disease and the altered cardiac rhythm of certain lesions of the spinal cord—for instance, chronic pachymeningitis—were examples of this. But the influence of disease of the spinal cord in the production of organic heart disease had not yet been demonstrated. Nevertheless, such cardiac changes do exist, according to M. Teissier. The mechanism of their production is either by the induction of trophic changes in the valves, or else by the causation of true dilatation of the cavities of the heart. Trophic troubles are represented by a rarefaction of the fibro-cellular tissue forming the basis of the valves, and chiefly the sigmoid valves of the aorta seem to be affected. This tissue is absorbed much in the same way as occurs in emphysema of the lungs. A small perforation is caused, which increases as the result of the traction of the elastic tissue elements which have remained or form the partitions between neighbouring holes of the same nature. Seven or eight may be seen at one orifice, and several may measure as much as six or seven millimetres in length. It is in the course of chronic affections, such as Friedreich's disease, locomotor ataxy, and paralysis agitans, that these lesions were observed; but they are in no case found more marked than in locomotor ataxy, especially when vaso-motor disorders have been conspicuous. Cardiac dilatations of spinal origin are still less common. A case was given in illustration. The patient was a merchant, who suffered from disease of the cervical portion of the spinal cord, the result of a railway accident. After a period of six months the patient, who had previously been free from heart mischief, began to suffer from palpitation and angina. False rhythm, evidence of dilatation, and the appearance of a basic bruit were found on physical examination. When seen by Teissier, eighteen months after the accident, there was evidence of great dilatation of the right side of the heart. A murmur was heard, which appeared to be exo-cardial. All the symptoms and signs of the cardiac disease subsided as the affection of the cervical part of the spinal cord passed away. Unilateral vaso-motor phenomena in the form of flushings were observed in the course of the case. In this annotation we have simply given an abstract of M. Teissier's paper.

THE HOSPITAL FLOWER MISSION.

THE season for the distribution of flowers in hospitals and infirmaries will soon have closed, but it is not perhaps too late to express our appreciation of the spirit which has daring the summer maintained this kind work among the sick. It may stand as a good general rule, that the more sensitive one is to bodily or mental pain, the more capable and desirous his mind is of finding relief in every attraction outside himself. Diversion in one or other form is what he seeks, and what on medical grounds is often prescribed for him, for diversion has much therapeutic value, and even a pharmacopœia of its own. Among its many remedies, none is readier to hand or more widely applicable than that which we are now considering. To no state of illness is the presence of wholesome flowers unsuitable. Almost every invalid can enjoy them through one or other sense. It should therefore be a point of skill with those whose office it is to distribute them to understand and be able to meet the several needs of those whom they visit. A blind man, for instance, cares nothing for a brilliant flower which has no smell; a subdued colour, again, is probably more grateful to a restless temperament than a bright one; a rank odour is in favour with no one; and so forth. The satisfaction with which these flower gifts are received affords abundant proof that judgment is generally used in their selection. There is much, too, in the fact of the gift, and in the way of giving. The sick man, like all others, values what is given him, not only for its intrinsic worth, but even more for the friendly feeling which accompanies it. Many words are not required to express this feeling. The absence of speech in such cases is often a kindness in itself, and this, we take it, most of the flower-distributors know. In consideration of these points, the fact that members of the Flower Mission are usually ward visitors as well, is a circumstance which must commend itself.

TYPHUS FEVER AT CHORLTON-ON-MEDLOCK.

A RATHER serious outbreak of typhus fever has occurred at Chorlton-upon-Medlock. According to the report of the clerk to the guardians eight cases have been shown to have originated in one house. The district may be fitly described as a fever den. The ventilation and drainage are such as to make it matter of surprise that the untoward event that has recently happened has been so long delayed. The inhabitants seem to be living in the most abject squalor. The houses, which are built on the back-to-back system, are in a wretched state of repair; in fact, nothing seems to have been done of recent date to improve their sanitary condition. Those that have become more dilapidated than the rest have been in whole or part appropriated as closets. In three of these a chamber used as a sleeping-room forms the roof of what is nothing more nor less than a cesspool. We learn that disinfectants have been freely distributed, and that the officers of the Nuisance Department of the Manchester Corporation have received strict orders as to the removal of refuse. This is a step in the right direction; but to grapple with the case in its entirety something of a more radical nature will have to be done. The simple removal of filth and the use of carbolic acid can only be of temporary benefit. Unless the account we have received is grossly exaggerated, and we have no reason to suppose that it is, we fear the Chorlton guardians have sufficient on their hands to tax their resources and ingenuity. From a sanitary point of view, the best course would be to close compulsorily all the houses in the district, with a view to their being demolished; but such a proceeding would necessarily involve the provision of domiciles for the evicted tenants, a matter which experience in large towns has shown to be of no inconsiderable importance.

WHOOPING-COUGH AND RESORCIN.

AN excellent monograph on the nature and treatment of whooping-cough has recently appeared at Rio de Janeiro[1] from the pen of M. Moncorvo, a most distinguished member of the medical profession in that country. He accepts in a great measure the consequences of the germ theory as regards pertussis, and looks on the affection as due to the presence of micrococci which proliferate abundantly upon the mucous membrane which coats the upper part of the larynx above the rima glottidis, where the epithelial cells become infiltrated, and which region appears to be the seat of election for the proliferation of the micrococci. Resorcin directly applied to the mucous membrane of the region indicated has led to diminution in the number of spasmodic attacks, which lose their intensity, whilst the total duration of the disease is shortened. The benefit is said to be wholly due to the resorcin, because no other means were employed.

[1] G. Leuzinger & Fils, 31, Rua do Ouvidor; and Paris, O. Berthier, 104, Boulevard Saint Germain.

Digitized by Google

The drug was used in the strength of a one per cent. aqueous solution as a topical application, by means of a soft brush mounted on a long handle. The application was made three, four, or five times a day.

THE DIAGNOSIS OF CANCER.

FROM a painstaking study of a series of cases M. Rommelaere believed that he had established the conclusion that cancerous affections were attended with a decrease in the amount of urea daily discharged. We have given in outline the results of this observer's examinations in vol. ii. 1883, pp. 379 and 737. MM. Dujardin-Beaumetz and Albert Robin have reconsidered the question, but seem to be unable to support the conclusions of M. Rommelaere. They have shown that the daily discharge of urea may remain normal or even augment whilst cancer is progressing, provided the patients take nourishment; further, it was demonstrated that the daily discharge of urea may diminish considerably in chronic affections of the internal viscera if the patients vomit or cease to take food.

DR. G. Y. HEATH.

OUR Newcastle-on-Tyne correspondent writes:—Some time ago I mentioned with regret the serious accident sustained by Dr. G. Y. Heath of this city, who was driving a pair of horses in an open vehicle, when owing to some mechanical defect in the carriage, it was overturned, and he was thrown with violence against the parapet of a bridge, fracturing four of his ribs. Thanks to the doctor's vigorous constitution and elastic mental organisation, he has made an excellent recovery, and is again to be seen in our midst, having resumed his professional duties. Everywhere he will receive a hearty welcome, for as a citizen, a consulting surgeon, and a teacher, he has long occupied a prominent position in the north of England.

LIGHT AND VEGETABLE CHEMISTRY.

THE effect of light on tissues destitute of chlorophyll has been recently investigated by MM. Bonnier and Mangin (Comptes Rendus, xcix., p. 160). Roots, rhizome, flowers, blanched plants, and parasitic plants without chlorophyll—e.g., monotropa—were the materials employed. It was uniformly found that the intensity of respiration was decreased, more carbonic acid being eliminated, and more oxygen absorbed when these structures were placed in darkness than when they were exposed to light. The amount of oxygen absorbed, however, bore the same proportion to the carbonic acid given off in light as in darkness.

THE LEIPSIC CHAIR OF PATHOLOGY.

SEVERAL *savants* have been mentioned as likely to succeed the late Professor Cohnheim in the important Chair of Pathological Anatomy at Leipsic. Amongst them are Dr. R. Koch of Berlin, Professor Klebs of Zurich, Professor Rindfleisch of Wurzburg, Professor Ziegler of Tübingen, and Professor Weigert. It is said that the first named has actually received the "call," and that he has replied by expressing his determination to remain in Berlin, where he will doubtless succeed Dr. Struck as Chief Director of the Board of Health, and be also nominated Professor of Hygiene. It is probable that the choice will lie between Klebs and Ziegler.

DEATH OF DR. OULMONT.

DR. OULMONT, honorary physician to the Hôtel Dieu, and member of the Academy of Medicine, died on the 18th inst. in the seventieth year of his age.

THE MEDICAL SOCIETIES.

THE vacation is gradually drawing to a close, and before long the various Societies will have again commenced work. The Obstetrical Society leads the way on October 8th; the Ophthalmological Society opens on the 9th, and the Clinical Society on the day following. The Pathological Society will hold its first meeting on October 21st; the Association of Medical Officers of Health on the 24th, and the Medical Society on the 27th of next month. The session of the Royal Medical and Chirurgical Society commences on October 28th, and the Epidemiological Society on Nov. 5th.

SEWER VENTILATING PIPES OPENING AT HIGH LEVELS.

WE are glad to see that the suggestion we made repeatedly some time ago for the benefit of Brighton has been adopted by the Corporation of the City of London, and that the Commissioners of Sewers are about to arrange with all builders of new houses to construct pipes for ventilating the sewers, and to carry them to a level above the roofs of the houses. When this is done the ground-level openings can be closed, and then the plague of sewer gas will be a thing of the past.

"HIGH" GAME.

IT is sheer wantonness to throw away game because it happens to be a little "high," but is it necessary to use permanganate of potash to purify it from the taint, though that is sometimes used successfully if carefully employed? It will generally suffice to cleanse the game thoroughly and wipe it quite dry with soft cloths, rubbing a little salt into the worst parts. Game which is simply "high," without being *putrid*, is particularly easy of digestion, and of great value to invalids.

A MINISTER OF HEALTH.

IN his presidential address at the Social Science Congress, Dr. Norman Chevers urged the need and importance of appointing a Minister of Health. We have so repeatedly insisted on the wisdom of creating such an office, that we cannot but hail the revival of the proposal by the President of the Health Department of a body largely representing public opinion.

THE International Association of Surgical Instrument-makers held its second annual meeting at Dresden on the 15th to the 18th inst. There were about seventy members present from Germany, Austro-Hungary, Switzerland, England, Roumania, Russia, &c.; and the Association has doubled in numbers since its formation last year. The objects are to protect the medical profession and the public from badly constructed appliances. The topics mainly discussed at this meeting concerned the establishment of a journal devoted to the publication of new and improved instruments, and the means for training the *employés* in the objects and methods of their work. The next meeting will be held at Berne.

THE Aberdeen University Court has appointed the following six gentlemen to be Extra Professorial Examiners in Medicine for next year—viz.:—Dr. John Alexander, Glasgow; Dr. Alex. Campbell, Dundee; Dr. Alfred H. Carter, Birmingham; Dr. J. A. MacWilliam, London; Mr. Frederick Treves, London; Dr. Francis Warner, London.

THE Harveian Oration will be delivered by Dr. Russell Reynolds, at the Royal College of Physicians, on Saturday, Oct. 18th, at 4 P.M.

THE *Bombay Gazette* says: "Cholera has broken out at Ecoaim and Penga de France, Goa, where five fatal cases have occurred. It appears that the disease has been imported by Hindoo pilgrims who have just returned from Pondichery, where cholera is prevalent."

WE learn from Indian papers that typhoid fever is very rife at Simla and Murree, which, in place of being "health-resorts," are, owing to the want of sanitary arrangements, proving themselves to be death-resorts.

DR. KOCH is now giving a course of lectures in Berlin, the purpose of which is to instruct military medical officers in the microscopic investigation of the cholera bacillus, with a view to the prompt detection of cases of Asiatic cholera.

IT will be interesting to many of our readers, especially at the present time, to learn that the Ocean Steam Yachting Company, Limited, purpose sending the *Ceylon* on a cruise to the Mediterranean as far as Alexandria.

WE learn that the medical officers of the Indian Medical Service propose to present to Mr. E. Gibson, M.P., a testimonial in recognition of his efforts to obtain a removal of certain grievances of which they complain.

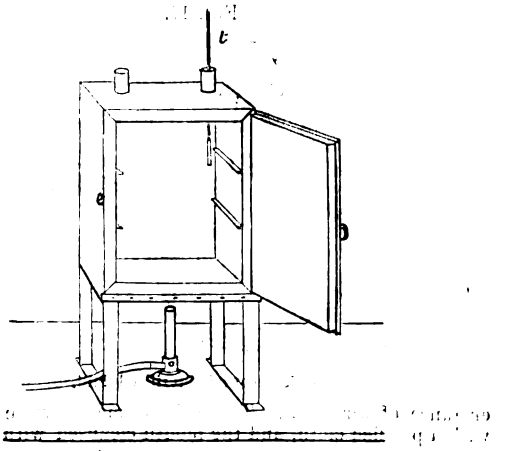
IT is understood that the scheme for the employment of female nurses in the naval hospitals is to come into operation experimentally at Haslar Hospital on Oct. 1st. Nine trained nurses have been engaged.

TYPHOID fever is reported to be on the increase in Paris. The Seine is in a foul state, smelling like an open sewer. Even the drinking water has a distinct odour which is only removed by boiling.

A SEVERE epidemic of measles is reported to be prevalent at Bolton.

THE BIOLOGICAL LABORATORY AT THE HEALTH EXHIBITION.

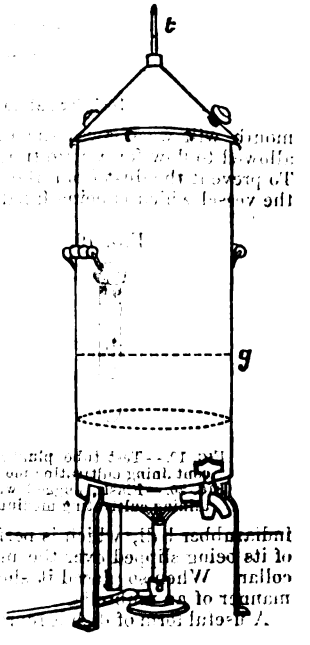
No. IV.



ORGANISMS PRODUCING CHANGE OF COLOUR IN THE MEDIA IN WHICH THEY GROW.

CERTAIN bacteria produce colours in the media in which they grow. They are characterised by their form and their manner of growth in solid media in the same way as others, and possess this striking feature in addition. The colour produced by an organism is always the same under the same circumstances, and is a constant character of the species. The colouring matter is round about the organisms, not in them; and in many cases it is formed only when in contact with the air. The bacteria of this character cultivated in the laboratory are the following: Micrococcus prodigiosus, which produces a crimson colour; Micrococcus Indicus, producing a bright rusty red; the "*violet*" and "*fluorescing*" bacilli; the bacilli of green and of blue pus; and a species of Sarcina, which produces a yellow colour. Two species of Torula are also cultivated, one of which produces a beautiful coral red ("Rosahefe") and the other a black colour.

METHODS OF CULTIVATION.



In cultivating the bacteria which have now been described, it is of essential importance to have trustworthy means of sterilising the apparatus and fluids used. In sterilisation by heat, it must be borne in mind that, besides the active, rapidly dividing form of the organism, which is readily killed by the temperature of boiling water, there is another form, that of the spore, which is more resisting. These may be raised to a considerably higher temperature in the dry state, without being killed. In order to ensure sterilisation of the vessels &c. used in cultivations, they are heated to a temperature of 150° C. for three hours. This is done in the hot box represented at Fig. 15. It is made of sheet iron, and the walls, floor, door, and top are double, and contain air. It is heated from below by a Bunsen's burner. The vessels to be sterilised are first cleaned and firmly plugged with cotton-wool.

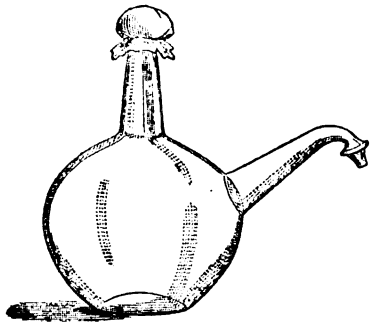
FIG. 15.

Hot box for sterilising apparatus, at a temperature of 150° C.

FIG. 16.

Steaming apparatus.

Fig. 16 represents a convenient form of *steaming apparatus*. It is a cylindrical box with a conical lid. An iron grating is fixed at a level below the middle, and serves to support what has to be steamed. The water is poured in from above, and heated by a Bunsen's burner. The box and lid are invested by a thick layer of felt, which reduces the loss of heat, and so maintains the interior at a uniform temperature. A hole in the top of the lid admits a thermometer, which is held in place by cotton-wool.



VESSELS.

A peculiar kind of flask is used to contain a sterilised fluid, and is so constructed that part of the fluid may be poured off without the remainder becoming infected from the air. It was introduced by Sir Joseph Lister. A wide neck opens into the body of the flask. To the side is attached a spout, which gradually narrows and is bent over at the end. A sort of collar a little above the mouth of the spout allows a cotton-wool cap to be fixed over it. When the flask contains some sterilised fluid both apertures are closed by means of cotton-wool caps. When it is desired to pour off some of the fluid, the cap is removed from the spout for the purpose. When sufficient liquid has passed out the flask is set upright, and the part of the contents

Digitized by Google

which is contained in the spout flows back into the body of the flask. There remain, however, in the extreme end, which is bent over, a few drops, and these serve the purpose of closing this orifice and preventing the

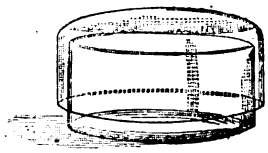


FIG. 17.

Flask to contain sterilised fluid.

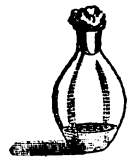
entrance of air by it. These drops may now be removed with a purified cloth, and the mouth cleansed with an antiseptic and covered again with the cap. On again removing liquid from the flask, the first part which flows over the

FIG. 18.

Dish for potato cultivation &c.

mouth will wash away the antiseptic, so that the stream is allowed to flow for a little time before the liquid is collected. To prevent the dust from the air falling into the mouth of the vessel which is being filled, it is convenient to use a half

FIG. 19. FIG. 20.



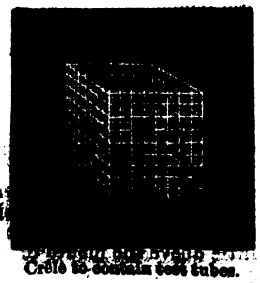


FIG. 19.—Test tube plugged with cotton-wool, and containing cultivating medium.
FIG. 20.—Flask plugged with cotton-wool, and containing cultivating medium.

indiarubber ball, which is perforated in the middle to admit of its being slipped over the mouth of the spout above the collar. When so placed it shelters the space below it in the manner of an umbrella.

A useful form of dish is represented in Fig. 18. It consists

FIG. 21.

Crate to contain test tubes.

of two similar parts, one of which fits over the other as a cover. The floor of the inner one is flat, so that plates &c. placed in it are approximately level. Cultivations are usually contained in test tubes. These should be wider than are generally employed for chemical purposes. When they are to be sterilised in the hot box they may conveniently be contained in the wire framework represented in Fig. 21. Fig. 20 represents a form of flask which is convenient for containing milk, bread infusion, &c.

The *inoculating needle* consists of a piece of platinum wire which is fixed in the end of a glass rod. Before it is used for inoculation it is passed through the flame of a spirit lamp, so as to kill any organisms which may be adhering to it.

Pharmacology and Therapeutics.

ROOT OF COTTON PLANT.

HAVING learnt that in America the root of the cotton plant (Gossypium herbaceum) is employed by doctors as a substitute for ergot of rye, M. Prochownick of Hamburg has studied the subject. There does not seem to be any glucoside or alkaloid in the root. Clinical observation goes to prove that a fresh infusion of the root best preserves the properties of the remedy. Administered as a fresh infusion in doses of from three to six or ten grammes, the root gives rise to intermittent uterine contractions like those pertaining to the natural process of parturition. Owing to these effects the drug may be given before the birth of the child, whereas ergot cannot be so recommended. The new remedy is not so powerful in its action on the smooth muscle fibre of the uterus, and so is of less value in post-partum hæmorrhage. M. Prochownick has used the infusion of the root of the cotton plant in some cases of metrorrhagia due to fibroid tumour. When given at the time of the hæmorrhage, the infusion does not influence the loss of blood; but if administered immediately after the bleeding the further losses are diminished in quantity, and occur at longer intervals. It is said that fibroid tumours have diminished in size under this treatment, and no increase in size has taken place in cases where the drug has been administered several months without intermission. The daily allowance is a single dose of ten grammes, or fifteen grammes in two doses. The same doses may be employed in cases of subinvolution. The commercial cotton plant ought to be macerated in cold water before making the infusion.

SCOPOLIA JAPONICA.

"Japanese belladonna root" has been the subject of an investigation by Professor Eykman, who confirms the results reported by Dr. Langgaard (*Pharmaceutical Journal*) so far as relates to the presence in the root of an alkaloid capable of dilating the pupil; it is stated that the mydriatic action is exercised by a solution of the strength of 1 in 5000. The fluorescence observed by other chemists in aqueous extracts of the root appear to be due to a non-nitrogenous body, obtained by exhaustion of the root with chloroform, and which has been named "scopoletin." It forms colourless needles or prismatic crystals, and is soluble in hot alcohol or boiling water; the aqueous solution has an acid reaction and both solutions a strong blue fluorescence. Scopoletin is said to be the decomposition product of a glucoside named "scopolin," which has a narcotic action but does not dilate the pupil.

KOLA NUT.

Specimens of fresh and dry kola nuts, Sterculia acuminata, a native of tropical Africa, were shown at the Société de Thérapeutique by M. Dujardin-Beaumetz. The nut contains a large proportion of caffeine, as well as a small quantity of theobromine and tannin. It is employed in the Soudan in two forms: as an infusion and for mastication, the nut being first roasted and then powdered. M. Dujardin-Beaumetz has used the article in cases of chronic diarrhœa with excellent results, thus confirming the statements of naval surgeons who have employed the remedy in the diarrhœa of Cochinchina. In cardiac affections where there is a tendency to asystole the drug has been found to act like coffee and caffeine, as a diuretic and as a tonic to the heart muscle. In many maladies showing signs of adynamia the tonic and stimulant properties of kola nut are of much value. M. Dujardin-Beaumetz has used the infusion of the burnt nut in the dose of fifteen grammes to a cup of water. An elixir or tincture has been prepared from the fresh nut and administered in doses of a dessert to a tablespoonful. Other alcoholic preparations may be made.

PHELLANDRIA.

This ancient remedy has received fresh attention, and is said to be a most valuable agent in treating various affections of the chest characterised by excessive cough, whether dry or attended with expectoration. Its action appears to be of a sedative as well as of an alterative and strengthening kind. Narcotism is not produced by its administration. It appears to have a special action against pulmonary phthisis. The most acceptable preparation is the syrup of phellandria used in a concentrated form. Other preparations, such as the arseniate of iron, may be advantageously prescribed with the syrup.

BORATE OF QUININE.

This salt of quinine has been prepared by Zimmer of Frankfort-on-the-Maine. It is an amber-coloured powder of faintly bitter taste, and soluble in an equal weight of water. The dose varies from eight to sixteen or more grains. In chronic and acute diseases it is said to be borne even better than the hydrochlorate, particularly if given in wafer capsules with water or a little wine. The preparation is cheaper than other salts of quinine.

CEREBRAL ANÆMIA AND HYPERÆMIA.

Curci has shown, by trepanning experiments on dogs, that chloral, chloroform, ether, paraldehyde, and quinine produce anæmia, whilst morphia and nitrite of amyl cause hyperæmia of the brain. Atropine in small doses has but little effect; in larger doses it is rather an "anémiant."

PURE CANNABINE.

Some months ago the tannate of cannabine was highly recommended as a soporific and substitute for morphine. But as the tannates of organic radicles are said to have a very indefinite composition, and are only of value in masking the taste of the alkaloid itself, Eugene Bombelon of Neuenahr has proposed to employ pure cannabine. The tannate is first prepared by precipitation, and then decomposed by means of oxide of zinc. Cannabine appears as a greenish-brown dry powder, volatile without residue on platinum foil. It is a prompt soporific in doses of ·05 to ·1 gramme, and is said not to be preceded by a period of excitement. The pure drug is tasteless, insoluble in water, but readily soluble in alcohol, ether, and chloroform.

KAIRIN.

Chlorhydrate of kairin has again been the subject of investigation—this time by M. Dreby of Lyons. As the use of the drug is yet in its infancy, we shall give here a *résumé* of the latest worker's conclusions. Kairin may be given in doses of from six to eight grammes a day without inconvenience to the patient. It may be given in all febrile states, but more especially in cases of meningitis, acute articular rheumatism, and typhoid fever. By its action on the heart and pulse the remedy is really antipyretic. Like quinine, it is a powerful antiseptic agent. Kairin may be an efficient antipyretic when quinine and other agents fail. It does not act by causing stimulation of the vaso-motor centre, nor by diminishing the excitability of the heat-regulating centres, but by lowering the activity of the tissue changes. The accidental discomforts, such as vomiting, frontal headache, collapse, and cyanosis, are very unfrequent and not marked, with the exception of the chill which attends each fresh elevation of temperature.

FRUIT OF CALABASH TREE.

Dr. Peckolt, of Rio Janeiro, who has contributed so much to the history of South American plants, has published a communication upon the fruit of the "calabash tree" (Crescentia cujete, L.) The plant is generally supposed to have been introduced into America from Africa by negroes; but Dr. Peckolt says that the Portuguese found it in America on their arrival. At any rate, it has long been utilised by the natives for economical and medicinal purposes. The flesh of the barely ripe fruit and the expressed juice of the fruit are popularly esteemed as medicines, and Dr. Peckolt confirms the estimate of the latter as a laxative. An alcoholic extract, in doses of ·10 gramme, had the effect of a mild aperient, and the quantity could be increased to ·5 gramme, which exercised a strong drastic action without griping or ill effects. As an application against erysipelas, the fresh pulp is boiled with water until it forms a black paste, to which vinegar is added and the whole boiled together, after which it is spread upon linen. A chemical examination of the fresh fruit pulp yielded a new organic acid, crystallising in plates, to which the name "crescentic acid" has been given. It was obtained by exhausting with water an alcoholic extract of the pulp, heating the aqueous solution with lead acetate, suspending the lead precipitate in water, and decomposing and removing the lead, then evaporating the solution to a syrupy consistence, and leaving it to crystallise in a cool place. Besides crescentic acid, there were found tartaric acid, citric and tannic acids, two resins, a bitter, and an aromatic extractive substance, and a colouring matter that appeared to resemble indigo (*Pharmaceutical Journal*).

FLUORIDE OF QUININE.

Fluoride of quinine has recently been recommended by Dr. Weddell of Calcutta in the treatment of enlarged spleen. He has investigated the action of fluoric acid and the fluorides, and has come to the conclusion that in cases of chronically enlarged spleens of malarial origin the effects obtained are often very striking. In very small doses the fluorides have produced marked benefit in cases of rickets and other diseases associated with malnutrition of the osseous system. Of the salts of fluoric acid, Dr. Weddell considers those of quinine or quinetum (i.e., of the mixed cinchona alkaloids) to be the best.

ARTIFICIAL (?) CONIINE.

Some researches made by Herr Ladenburg some time ago led him to believe that some propyl derivatives of pyridine had a close resemblance to the natural alkaloid conia. After some trouble the one of these derivatives which appeared to be the most promising (α—isopropylpyridine) has been isolated and purified. The smell of the base is described as being strikingly similar to that of conia, and some experiments on frogs showed that the two bases (artificial and natural coniine) correspond in their physiological action. The specific gravity of α—isopropylpyridine at 0° C. is ·8660, that of coniine being ·8625; the former boils between 162° and 164° C.; coniine boiling at about four degrees higher. The two hydrochlorates, the hydrobromates, and the platinum salts correspond in crystallisation and solubility, but the hydrochlorates and hydrobromates differ slightly as to their melting points. The two bases also behave similarly towards certain precipitants. Herr Landenburg is inclined to look on the slight differences hitherto observed as being connected with the optical inactivity of the artificial base, and he thinks it is possible that if the base can be split up into its two optically active components, the dextro-rotatory portion will prove to be perfectly identical with conia.

SALICYLATE OF ATROPINE.

Salicylate of atropine appears to be in some quarters displacing the sulphate. Herr Frederici has prepared the neutral salt by dissolving the atropine (twenty-three parts) with the aid of gentle heat in a suitable quantity of pure alcohol, and then adding the salicylic acid gradually to complete neutralisation (eighteen parts), the solution being carefully tested with litmus paper during the operation. The liquid is then evaporated in a water bath to a gelatinous consistence, the mass assuming an amber colour, and the drying is finished in a sand bath or drying closet. The compound deliquesces quickly when exposed to the atmosphere, but is said to keep well if properly preserved, though the solution is very unstable.

CONVALLARIA MAJALIS.

As the result of a series of experiments made by M. Reboul on the physiological action of convallaria on the heart of warm-blooded animals, the following conclusions have been drawn:—Convallaria acts primarily on the nervous system of the heart, and more especially on its intracardiac elements; the chief effects observed consisted in the slowing or arrest of the cardiac beats (*Lyon Médical*, Nos. 37 and 38). Several tracings illustrating the effects of the drug on the cardiac beats and blood-pressure are given in the paper by Reboul.

THE Director-General of the Army Medical Department visited Aldershot on the 19th inst. for the purpose of examining the medical officers who have been undergoing a course of Army Hospital Corps instruction during the past three months. Dr. Crawford also examined two large classes of non-commissioned officers and men of the Army Hospital Corps who have been undergoing the special course for some months past.

THE INTERNATIONAL HEALTH EXHIBITION.

COWLS AND VENTILATORS.

THE problem of ventilation should occupy a large space at the Health Exhibition. It is a question that affects everybody. Whether well or ill, an adequate air supply is equally indispensable for the maintenance of health or the curing of disease. At the Health Exhibition this all-important question is treated in a somewhat irregular manner. There is a small gallery or annexe close to the Central Gallery devoted exclusively to ventilation, where rival cowls in regimental array stand in long rows defiantly facing each other. But many more cowls may be found in quite another part of the Exhibition—namely, the section devoted to machinery in motion. We cannot attempt to describe individually all these contrivances; the battle of cowls has not yet been definitively fought. There are three or four rival principles governing the manufacture of cowls, but the votaries of each system imitate each other so closely that it is almost impossible to discern any crucial difference between them. Best known among the manufacturers of ventilating cowls is the name of Boyle, but in close opposition, and acting on a very similar principle, are the ventilators of Messrs. C. Kite and Co., Mr. Buchan's ventilator, and others. In each case the air strikes upon the angle of a metallic plate and is deflected to either side. The deflected wind passes in front of an opening, and produces a suction which creates the up draught. This opening is protected from the direct current of air by a metallic plate or shield; thus the air cannot blow over the chimney or pipe, cannot pass through the ventilator, but is turned aside; and this passing round instead of across the pipe gives rise to the upward suction within the pipe, which almost entirely obviates the danger of a down draught. A plane pipe without any cowl will, it has been shown, draw up, under certain conditions, as much air as the best ventilating cowls; but it cannot prevent the occasional down currents, and is less effective when there is only a very slight wind blowing. Mr. Buchan asserts that on one occasion his ventilator drew up 82,739 feet more air in eighteen hours than any of the rival ventilators with which it was competing. On the other hand, Messrs. Kite and Co.'s ventilators are much cheaper, and no one has studied the question without meeting endless and voluminous reports in favour of Boyle's patent. In any case, none of these are new inventions; and, indeed, though this section of the Exhibition is useful, it is certainly not very fruitful in new ideas.

Other cowls also act by deflection, but the wind is allowed to pass over the top of the pipe. In this case the deflectors are horizontal instead of perpendicular. The wind is thrown upon a covering and deflected at an obtuse angle that prevents its rushing down the pipe, and in describing this curve it produces a vacuum and consequent suction. Messrs. Sharp and Co. exhibit several cowls that work on this principle, and the same may be said of the exhibits of Dr. H. B. Dows' cowls, which has the further advantage of great simplicity. Steven's patent is very similer, and extensively patronised, while Kershaw's is a little more complicated and a trifle dearer. Both Messrs. Hill and Hey and Benjamin Hainsworth work on the same principle, but they combine their exhaust cowls with an inlet. This is a method we are not prepared to approve unless it be applied in a very different manner from that shown in the prospectuses of these firms. The cowl communicates with the centre of the room or apartment, and at once lets down air and draws air up. This double action is supposed to ventilate the room, but we fear it will only ventilate the air shaft, for if the inlet be not at some distance from the outlet a large portion of the air brought into the room will be drawn out again before it has time to reach the inmates. The last-mentioned firm also shows cowls constructed on the third of the four leading methods to which we have alluded. These are cowls which revolve either by the force of the wind or by the employment of some artificial power. In revolving the cowls act upon an archimedian screw below, which draws up the air within the pipe or shaft. Messrs. Ewart and Son and Mr. James Howorth also employ the archimedian screw, but the latter is able to apply it in a horizontal as well as a vertical position.

The fourth principle on which these cowls are built is similar to that which we described when speaking of the Papier ventilator exhibited in the French court. The action in this case is produced by imparting a rotatory motion to the air as it blows into the cowls. For this it suffices to make channels of a screw-like shape, and the air passing up these is converted into a sort of whirlwind when it reaches the centre and summit of the pipe or air shaft. This whirlwind has the effect of drawing up the air below, which rushes up to fill in the vacuum of the spiral. Messrs. W. Lord and Co., in their patents brought out last year, have cleverly contrived blades so as to catch the wind which ever way it may blow, and have also applied their system to railway carriages, where it is very much wanted. Lambs' ventilators revolve while giving a spiral motion to the air, and have been also much recommended. These cowls are employed for chimneys as well as for ventilators. Another chimney cowl is brought out by the Atmospheric Cowl Company, similarly based on the spiral system. The air in this case is admitted by a long spiral slit, which, however, is so narrow that it obviously runs great risk of being choked up with soot.

Instead of one or two expensive cowls, Mr. H. Thompson, C.E., has devised a ventilating ridge-tile, which he proposes to place along the entire ridge of the houses. Shafts communicating from the ceiling of each room to the attic would carry away the heated atmosphere. How far a down draught might result is an open question. But a little extra expense would obviate this danger. Mr. Thompson has an ornamental glass globe which he places near the outlet. The globe is loaded with mercury, and a weighted tube rises as the heat of the room expands the mercury. This action opens the valve in the outlet, the warm air escapes and automatic action is secured. The facility of application and the inexpensive nature of these contrivances commend themselves to all who are about to build houses.

With respect to inlets for ventilation, Ellison's conical ventilators are specially worthy of notice. These were exhibited during the Medical Congress of 1881, and we then described them at some length. The principle is that air should be admitted as through a trumpet. It is then so diffused as to prevent draught; but if it comes through a straight aperture or tube it will travel in a straight line, and therefore cause a cutting draught. Messrs. Hale and Co. have a more elaborate system of inlet by which the air is carefully diffused before it is admitted into the room. Doubtless draughts are thus avoided, but some scientific experiments should be instituted to ascertain how far these precautions reduce the volume of air drawn in.

We also observed a great number of patent window sashes which are intended to prevent accidents while cleaning and to facilitate ventilation. These are great improvements on the clumsy method generally used. We would recommend Meakin's sash fastener and opener, which by rendering the closing and opening of windows a matter of great facility incidentally promotes ventilation; as the window can swing forward they can be cleaned without danger. Mr. W. W. Nicholls has a method for opening both windows at once, the one balancing the other. For fanlights Leggott's and Bruce's patents may be recommended; but Messrs. Rownson, Drew, and Co. exhibit, in the South Central Gallery, an improved folding lattice shutter that will contribute most effectively to the ventilation of houses, especially when placed in somewhat isolated positions, suburban villas, &c. This is a strong, compact trelliswork fixed inside the window. It would be more difficult to break through this folding lattice shutter than through an ordinary window, so that the house may be thoroughly aired even when there is no one left to guard it.

Before concluding, there is one phase remaining, to which however, we can allude only in an apologetic manner, for it is impossible to render justice to the question in a short paragraph,—we mean the problems involved in the use of mechanical ventilators, such as the huge bells of the Norton ventilator, which, moving up and down in a cylinder, forcibly pump out the foul air from the cabins of ships; or Aland's patent induction ventilating fan for coalpits, and Capell's double-power blast fan. For the ventilation of houses, and especially public or large buildings, Blackman's air-propeller should be studied with attention. The theory on which this invention is based is that "the amount of air moved per horse power by any air-moving machine has definite relation to its feed and delivery surfaces." To ensure the best result it is maintained that the mechanical propeller should not be enclosed in any case or tube, but be allowed to feed itself from all sides. Acting upon this, the

Digitized by Google

fans in question may be seen in full action, and crowds of visitors daily expose themselves to the powerful currents of air they create.

In conclusion, we regret to note the Æolus waterspray ventilator can only be seen in action at the vegetarian restaurant, as it well deserves to take its place among the many contrivances which we have examined.

SOCIAL SCIENCE CONGRESS.

THE following is a brief abstract of the most important papers which were read in the Health Department of the Social Science Congress, held at Birmingham on Sept. 17th and following days.

Dr. Norman Chevers, President of the Health Department, in his address on Health in England remarked that no power of concentrating language would enable him to detail within the space of time at his disposal even a bare list of the grave sanitary shortcomings which every stranger must perceive within a week after he sets foot on British chalk; and that though no one esteemed and gloried in more appreciatively than he did the admirable work done in the past half century by such sanitarians as Chadwick, Miss Nightingale, Simon, Sidney Herbert, Sutherland, Parkes, Gavin Milroy, Benjamin Richardson, Netten Radcliffe, and George Buchanan, yet he recognised with painful clearness the disheartening fact that without powers full almost to benevolent absolutism, the benefit conferred upon their suffering fellow-countrymen, even by such enlightened administrators of the public health as these, must always be very tardy in its advance and very narrow in its scope. He could not hope to live to see the day, but confidently anticipated that all who do will find that in a very short time after the appointment of a Minister of Public Health, invested with great powers, against which all narrow self-interested opposition will be futile, and commanding large means, nothing more will be heard of sewage-poisoned rivers, smoke and fog-blocked cities, or of public buildings and attractive suburban retreats constructed upon burial-grounds, quagmires, or abandoned lay-stalls; and, in addition, due regard will doubtless then be paid to the control of our charities for the sick, of some of which, as they were ruled in his time, an old writer said, "They are like children with water on the brain: the limbs wither as the heads increase."

Mr. Bayley described a method of treating human bodies for the prevention of putrefactive changes.

Dr. Pringle, in a paper on Asiatic Cholera and some of the Lessons learnt in its Home in India during Thirty Years' Service, divided the subject into four heads—viz., Origin, Spread, Treatment, and Prevention. Origin: With the single exception of the cholera epidemic of 1882–83, which appeared to come back from the Punjab to Bengal, every cholera epidemic of the past thirty years has originated in Lower Bengal, and worked up to the north-west, and so passed out of India. Spread: Judged by the experience of thirty years' observation in India, and the spread of the cholera outbreak from Juggernauth, on the Bay of Bengal, in 1856, and those at Hurdwar, on the Ganges, at the foot of the Himalayas, in 1867 and 1879, at all three of which Dr. Pringle was present as medical and sanitary officer of the district, Dr. Pringle appeared to favour the view that the disease spreads by human intercourse, though not in the contagious and infectious manner seen in small-pox and similar diseases. Treatment: Dr. Pringle's views on this subject were those of believers in the theory of elimination of the poison, and he was strongly opposed to the employment of opiates and alcoholic stimulants, as he was satisfied that, in the stage of reaction, and consequent reabsorption following that of collapse, they tended to the production of, if they did not actually produce, the febrile symptoms and those of congestion, which often proved fatal after the stage of collapse had been passed through. Dr. Pringle also contended that there was no such stage as premonitory diarrhœa. In true cases of Asiatic cholera in India, hundreds of instances are known in which the sufferers were in perfect health till they were seized with cholera, which, in a few hours generally, in severe epidemics proved fatal. Prevention: That which removes the conditions which produce diarrhœa and dysentery, and which seeks out and treats these cases, is the best measure of prevention. Quarantine on land is worse than useless: it conceals the disease when present, and secretly admits it when, till then, absent. In the case of railway changing and halting stations, special arrangements for the inspection and treatment and ultimate removal to destination of all suspicious or real cases of cholera will obviously be most beneficial. In the case of infected ships, a careful and independent inspection of crew and passengers should be made, and, as in changing and halting stations, special arrangements either on board another ship or on land should be available for the cure and treatment of the sick, and when the ship is empty it should be thoroughly fumigated and cleaned out.

Dr. Pringle also read a paper on Vaccination and Re-vaccination.

Dr. Page read a paper on the Sanitary Test Value of the Mean Mortality, with Suggested Means for Reduction of Child Mortality.

Mr. T. Pritchard, in discussing the question, What are the Best Means of Dealing with Town Sewage? premised that the answer some fifteen to twenty years ago would have been in favour of irrigation; the experience of the last few years had, however, caused a considerable modification of his opinion as to the best method for adoption, varying according to local circumstances and conditions. The author called attention to the conflicting opinions of chemists regarding the oxidising properties of rivers, for the purification of sewage effluent, when discharged into running water many times its volume, and pointed out that there are three methods generally adopted in this country for the disposal of town sewage—viz.: 1. Land purification. 2. Chemical precipitation. 3. Discharge into the sea. After discussing these methods in detail, the author concluded his paper by stating that no one particular system for the treatment of town sewage could be adopted for universal use, but that the local conditions and circumstances connected with each town must be carefully considered and a method of sewage disposal prepared in accordance therewith.

Mr. Lawson Tait, in a paper on the Utilisation of Town Refuse, remarked that few of the many questions which have engaged the efforts of sanitary authorities during the brief period in which real attention has been given to the care of the public health have caused so much anxiety as the disposal of town refuse. In a few favoured places the difficulties had not been pressing, but in a town like Birmingham, the rapidity of whose growth has been almost unexampled, and situated as it is in the centre of England, with a river no larger than a brook, the difficulties and dangers of the disposal of refuse have risen to an extent probably unknown in other large centres of population. Mr. Tait then described the process for the utilisation of the refuse as adopted in Birmingham, by burning the household refuse and subjecting the excreta to intense heat—these two varieties of refuse being in collection kept entirely separate.

Dr. Joseph Rogers read a paper on the Relations between Boards of Guardians and their Medical Officers. In introducing the subject, Dr. Rogers gave a brief sketch of the causes which led to the introduction of the new Poor-law, 1834, and showed that whilst every conceivable factor in the production of pauperism was inquired into by the Commission that sat in 1831, 1832, and 1833, the subject of sickness was altogether ignored; that as a result the Commission did not refer to this question in their report, and that the arrangements made for the treatment of the sick poor were conceived in the harshest and falsest economic spirit. Dr. Rogers then pointed out the nature of the reforms he advocated, which were an extension of the dispensary system, which had been established in London and in Ireland, to all unions and parishes in England and Wales; and, with the view to the improvement of the status and emoluments of medical officers, that their stipends should be paid wholly either from a county rate or from the Consolidated Fund; and that a larger measure of discretion should be accorded to those gentlemen in determining what medical comforts should be given to the sick poor under their charge.

Mr. R. Denny Urlin, in a paper on the Future of some of the London Hospitals, stated that there have been counted in a single copy of a London evening paper no fewer than ten urgent appeals for pecuniary aid on behalf of hospitals in or near to London. From many such instances it may fairly be concluded that, in spite of Saturday and Sunday Funds, there are a number of unendowed hospitals which cannot now pay their way; while as London grows, and contributions fall off, some of them will probably collapse. If this fate befell some of the small specialist institutions it would be no great loss; but there are others which from their posi-

Digitized by Google

tion and mode of operation have become public necessities, and, if they are to be maintained, there must be sooner or later a subvention from public funds. This will certainly bring with it some degree of inspection and control, which will be advantageous. It is reasonable that any building which shelters a large number of inmates should be periodically inspected by a responsible officer. At present a hospital may be planned, built, and carried on without any due security for the safety and health of the inmates, and solely at the caprice of a secretary and a board; it may be rarely meeting and without special aptitude for this important work. Inspection for sanitary and other purposes should be compulsory in case of all such structures, while audit should be imposed as the condition of obtaining any grant from Government or local funds.

Dr. P. Murray Braidwood, in a paper on Hospital Ships, after describing the drawings he exhibited of two designs representing vessels of different classes or types, but of similar dimensions—viz., what are known as "spar deck" and "shade deck" steamers, remarked that at present the method adopted by Governments is to charter at the lowest freight rate the largest steamers available, and to convert them into hospital ships. Now, all medical men know that the treatment of sick and wounded persons in a building which has been converted from an ordinary dwelling-house into a hospital is always most unsatisfactory. Hence it is deemed necessary to erect, on shore buildings specially constructed for hospital purposes. It seemed to the author, therefore, that modern advancement requires that we afford equally suitable accommodation and arrangements for the treatment of the sick and wounded at sea. The objection of expense the author met by stating that it would be cheaper to build outright a hospital ship than to convert a trading steamer into one, and that such a steamer would serve best for the transport of troops, and if not required for either of these purposes, it could be utilised as a ship for convalescents.

Dr. Ashby, in considering how far may the average death-rate of a population be considered an efficient test of its sanitary condition, and by what means can the high death-rate of children be reduced, remarked that the causes of the high mortality are very complex, and include the influence of the health and life conditions of the parents in producing weakly children, insanitary conditions of dwellings, insufficient ventilation of rooms, and effects of smoky atmosphere, improper feeding of young infants, employment of mothers in mills &c., bad effects of burial clubs, poverty, degradation, and drunkenness of parents. In discussing the means to be adopted to reduce the high death-rate the author alluded to:—1. Improvement in the surroundings and homes of the working classes, provision of open spaces, diminution of smoke, improved dwellings, checks on burial clubs and friendly societies. 2. Improvement in the habits and status of the working classes by means of education, by extension of ladies' sanitary associations for systematic work among the poor.

In the opening of a paper on the same subject, Mr. Humphreys urged the public need for some numerical test of sanitary condition, and to the increasing use of the death-rate for this purpose he referred much of that growth of public interest in health matters which has been the mainspring of recent sanitary progress. In view of this plea for a numerical test, and of the good that has already resulted from the use of the death-rate for this purpose, the inexpediency of its surrender was pointed out, except under one of two conditions: unless its use can be proved to be absolutely mischievous, or unless a better numerical test could be provided in its place. As the result of his investigations, Mr. Humphreys considers that death-rates afford a numerical test of health condition sufficiently approximative and trustworthy to be useful, in the future as they have been in the past, as a stimulant of the public interest in health progress.

In a paper entitled a Plea for Homes and Hospitals for Incurable and Chronic Diseases, with special reference to the Midland Counties Home for Incurables at Leamington, Dr. J. Lancaster Ranking briefly reviewed the development of hospitals, and the provision which has been made throughout the length and breadth of the land for hospitals for special diseases, and classes of disease, and for convalescents; but remarked that homes and hospitals for incurable and chronic diseases are few, and insufficient for the wants of the community.

In discussing the best method of dealing with the products of combustion, Captain Douglas Galton stated that if we are ever to obtain an atmosphere free from smoke over the vast aggregation of buildings of which our towns are now composed, we can only do so by abandoning the crude method of burning coal in the manner of our early ancestors, and we must resort to the more scientific method of using gaseous fuel.

Surgeon-Major George A. Hutton, in a paper entitled Facts and Figures connected with "First Aid," and the Carriage of Sick and Injured Persons, said that although he looked on this question as affecting everyone—prince, peer, and peasant alike—for all are subject to accident, yet largely and in the main he considered it a working-man's question. He asserted that ambulance work would largely promote kindly, good, and reciprocal feeling amongst all classes, especially employers and their workmen, and he therefore claimed for it national recognition.

MR. SIMON ON JOHN NETTEN RADCLIFFE.

[THE following notes on the late Mr. Radcliffe were most kindly sent us for use anonymously, and not for independent publication. But they are so precious that we have, after some amicable contention, prevailed on their author to allow them to appear under his name, and that in the informal and epistolary style in which they reached us—too late for use last week. Even without the initials, the authorship could not be concealed. Apart from their value as an eloquent testimony to Radcliffe from the one man who is conspicuously able to give it, the notes have so much interest in regard to sanitary legislation, work, and literature, that we feel very grateful to the author for allowing us to publish them just as they stand. Mr. Simon, as may be inferred, writes away from books and the opportunities of reference, but we may safely trust his memory for the accuracy of the chief dates and facts, as we may his judgment on the merits of one of the best public servants the State has ever had, who has died all too soon either for its interests or his own.—ED. L.]

"First of all (for certainly here I need make no reference) let me say what very warm regard and admiration I had for him. Certain quite superficial peculiarities which he had—on the one hand, a somewhat unpunctuated or unaccentuated mode of speech, and, on the other hand, a somewhat frequent preference for semi-sarcastic (though never ill-natured) forms of expression—may sometimes have hidden from casual observers particular features of his real character; but I think it may truly be said of him that he grew in the respect and affection of his friends in proportion to the duration and familiarity of their knowledge of him. Thoroughly kind-hearted (indeed soft-hearted) towards his fellow-creatures, always generous of help and sympathy, very susceptible of personal attachment, and very staunch in retaining it, he always seemed to me to be equally characterised by the straightforward truthfulness and loyalty of a remarkably simple and honest nature. His intellect was of a typically English sort, and in that sort seemed to me one of the ablest I knew. I need not tell you that it was eminently practical. Whatever book-learning he had, or whatever imagination, or whatever abstract philosophy, one never saw any separate flourish of any of them; one saw, when he was at duty, a workman of rare vigour, thoroughly intent on what he had to do, and pursuing that object with inflexible perseverance; but of personal flourish, never a trace. When he had to investigate, he investigated with such dogged constancy and such absolute regard for truth as I have never seen surpassed; and when he had to advise, his advice was characterised in the same eminent degree by its wise regard to practicality. Widely experienced in everyday life, and highly vigilant in observation, he was, above all, greatly gifted with common sense, and his abundant technical knowledge was always under the control and guidance of that Anglo-Saxon form of genius.

"From nearly twenty years ago he has been well known, not only to me, but, I should suppose, to our profession at large,

Digitized by Google

as one of the ablest of the small staff of men who were then beginning to head the progress of State Medicine in this country; and illustrations of the admirable quality of his work are to be found in the successive annual Reports of the Medical Department of the Privy Council, and, after 1871, of the Medical Department of the Local Government Board. Among reports which he made on the subject of particular local outbreaks of disease investigated by him there are especially three which I count classical. 1. The Report on the very remarkable Outbreak of Cholera at Theydon-Bois, near Epping, in 1865. 2. The Report on the East London Cholera Epidemic of 1866, and its relation to the use of the East London Company's Supply of Water. 3. The Report on the terrible Epidemic of Enteric Fever which prevailed in and about Marylebone in 1873, in consequence of a Dairy Company's Distribution of Infected Milk. These Reports ought to be familiarly known to every officer of health, not only for the tremendous significance of the lessons which they teach, but as examples to be studied and remembered of the minutely cautious and complete way in which local epidemics require to be investigated by anyone who aspires to advise on them. Equally classical in the literature of preventive medicine, though in another direction than the above, are the expositions which he made in matters of epidemiological history, more particularly in 1866 and 1875, with reference to the successive steps by which cholera had advanced from India and had been diffused to various countries of Europe; and in various late years with reference to the diffusions of Levantine plague. His acquaintance with the 'time and place' relations of epidemic and endemic diseases was unusually large and accurate, particularly in respect of cholera and plague, and of the therewith-connected questions of traffic between places and countries. It was, I believe, quite unique; it was like the familiar knowledge which a Charing-cross policeman is supposed to have of the omnibuses which pass his beat; and in the distribution of the work of the Medical Department I used always to look to him as a specialist in that branch of information.

"By the passing of the Sanitary Act of 1866 (which I always consider the best result and reward of my years of official life) both the responsibilities of Local Authorities for the prevention of disease, and likewise the responsibility of the Central Government for looking after them in that duty, were very largely increased; and that being the case, the Medical Department found it must prepare to communicate with the local authorities far more systematically than before on questions of disease-prevention of all sorts. Two branches of this duty, larger and more pressing than perhaps all other branches put together, were the two which related (1) to the prevention of filth-diseases, and (2) to the prevention of the spread of contagion. I need not here attempt to explain at length the policy which I tried to make effective for those and like purposes, but I must mention that at the beginning of 1869 the then new Chancellor of the Exchequer (Mr. Lowe) cordially consented to augment the staff of the Medical Department; that hereupon, for the first time, Buchanan and Radcliffe became permanent officers of the Medical Department; and that from this time they took a more active part with me in what followed—viz., in preparing schemes of detailed information and suggestion for local authorities with reference to local sanitary purposes, such as prevention of filth-nuisances, provision of hospital accommodation for infectiously diseased persons, &c. Much of this sort of work was at first done by them more or less jointly, as especially in my twelfth Privy Council Report, their studies of the various 'not-watercloset' sorts of privy contrivance which were in successful use in various places. Gradually Radcliffe gave more time to the observation of foreign epidemics, combining with that work the kindred specialism of helping port-authorities to understand their sanitary responsibilities with regard to ship-borne infectious disease. Under the Sanitary Act of 1866, and in accordance with the advice I had given in my Report of that year, we had done all we could to develop, instead of the obsolete quarantine system of the country, a system of dealing with infectious arrivals at ports in substantially the same way as inland infections were to be dealt with—i.e., by hospital isolation under the auspices of the local sanitary authority; and cholera only be dealt with on like principles with small-pox or typhus. Many of Radcliffe's local reports or memoranda on cases of that sort were highly interesting, but I have not at hand the means of particularising any.

"In 1874, when I codified in a Report to the Local Government Board all that I had to say on the subject of filth-diseases, I gave as an appendix to my own paper a thoroughly worked new study by him of the prevention of excremental nuisances—a most valuable second casting of the studies of 1869. And it seems to me that here again is a report of his which every officer of health in the country ought to know with the most exact familiarity.

"In 1875, when, as you may remember, there had been considerable cholera-alarms in Europe for the last year or two, and when an International Conference on Cholera had been held at Vienna, I found it desirable to re-examine our scientific standpoint in relation to the opinions of other countries; and the occasion was also taken for Radcliffe to extend his cholera paper of 1866 into a report for the whole decennial period. For the guidance of European opinion on the question of Red Sea quarantine, and other such questions, the mass of evidence given in that report with regard to the many ways by which cholera, so often as it grows in India, tends to reach Europe, is, in my opinion, the most instructive document in existence; and the man who can resist that kind of evidence must be either an idiot or a quarantine *employé*. To the ordinary medical reader it might be too laborious to study the paper, but as a *pièce de résistance* for the English Government when it has to confer with other Governments about their quarantine proposals the report is simply invaluable, and worth even the immense labour which Radcliffe bestowed on its compilation.

"As for poor Radcliffe's actual death, under the conditions which had so grievously come to him, of course it would be absurd to express regret. The moment for regret—and to me the regret was indeed extreme—was when I saw, now two years ago, that the strength, and usefulness, and happiness of his life had gone from him. I suppose that the disease to which he eventually succumbed must have been creeping on him from a much earlier period, and that it accounted for the degree to which, in years after my withdrawal from office, he developed in his way of work a certain slowness which, in its moderate degrees, I had previously noticed in him as peculiar. In regard of that question of rate of work, Radcliffe had from old been a psychological curiosity: for while undoubtedly he was capable of what in so industrious a worker seemed a quite extraordinary slowness of work, and this even at times when he was in his best health, he could be of equally extraordinary swiftness in cases where swiftness was evidently essential. Where, for instance, there was necessity to judge off-hand on the advice to be given to a local authority in an emergency or a panic, his opinion was formed and expressed with an almost military promptitude; and I do not remember that any such prompt judgment of his ever seemed to me mistaken. In what he considered his provisional judgment on the broad facts of cases, he never loitered, but yet never seemed to go wrong; and the slowness which, even in my days there, used to be proverbial, attached entirely to the extraordinary zeal which possessed him to give a finish of absolute certainty (in matters of fact) to passages which in general were of quite subordinate significance. Even on occasions when I was obliged to wish he could more easily satisfy his extremely fastidious self-criticism in matters of that sort, I could not but immensely respect the scrupulous regard for truth which was at the root of it. Noble steadfastness of work, abhorrence of incomplete testimony, and in general a loathing for pretentious and scamped work, were characteristic of him; and no doubt he strove to work up to his own high standards of accuracy and completeness long after he had begun to feel (through ill-health) more and more difficulty in the endeavour. I suspect, too, that the later circumstances of the office, allowing him to give more and more time to documentary compilations, and drawing him out less and less into the practical work in which he was so eminently qualified to excel, was probably unfortunate for his health. The public service, owing to the changes in the office, derived from his great qualities far less good than it might have got, and has lost in him (not by this last removal, but by the long incapacitation which led to it) such a man as it will hardly replace.

"Folkestone, Sept. 16th, 1884." "J. S."

PRESENTATION.—Dr. C. T. Ewart has, upon his resignation of the post of resident medical officer at the Fisherton House Asylum, Salisbury, been presented by the attendants, nurses, and inmates of that institution with an escritoire and inkstand.

THE BENEVOLENT FUND OF THE BRITISH DENTAL ASSOCIATION.

IN the report of the annual meeting of the British Dental Association at Edinburgh, which appeared in our issue of Sept. 6th, pressure on our space compelled us to omit the first annual report of the above Benevolent Fund, which was inaugurated last year at Plymouth. The managing committee, through its chairman, Mr. John Tomes, reported that the fund was originally intended to be applied only to the relief of necessitous members of the Association, their widows and orphans; but, several most urgent cases having arisen during the year, it became necessary to extend the field of usefulness, and the rules as now amended permit of help being given to any deserving cases of necessity, with the sole proviso that the recipients must be registered dentists or the widows or orphans of such, strict inquiry being made. The treasurer (Mr. A. J. Woodhouse) reported that the donations and subscriptions promised and received amounted to £848 18s., and that relief had been administered to the extent of about £120 in eight cases in all. Sir Edwin Saunders, one of the trustees, said that £530 had been invested in Consols, and the vice-chairman, Mr. Dennant, explained that the committee had no intention of pauperising those aided, but of relieving "the distress of the widow, the helplessness of the orphan, and the dire misfortune of sudden calamity overtaking a professional brother." Their desire was to help the widows to earn their own living, and to find homes and education for the orphans. Mr. S. J. Hutchinson, who acted as honorary secretary (in the absence of Mr. Oakley Coles), stated that a local committee for Scotland had been formed by the Scottish Branch at this meeting, and that in the two dental schools in London, and in that of Edinburgh, it was proposed to establish free scholarships in the event of any of the pupils now being educated at the cost of the fund, deserving free education at any of these hospitals, which would most likely be granted by the medical staff of every dental school in the kingdom.

REPORTS OF THE STATE BOARD OF HEALTH OF NEW YORK.

A VALUABLE series of special reports has been issued by the State Board of Health of New York, each report dealing with some one special subject, and being complete in itself; and in this respect they very much resemble the reports of the inspectors of the Medical Department of the Local Government Board in this country. But they are by no means confined to medical subjects; one, for example, gives an exhaustive account on the drainage of the Tonawanda and Oak-Orchard Swamps, and another deals with the system of sewerage for the village of Peekskill, and these latter might justly form a type of the species of report which, in our opinion, should issue from the engineering department connected with our Central Sanitary Board. From the diagrams attached to some of the reports, we observe that through-ventilation of house-drains is strongly advocated, but the arrangement of openings by which it is effected differs from that suggested in the annotated model bye-laws in use here, for the two openings are much on the same level, both being secured by means of pipes carried to the top of the house. A more certain way of ensuring a through current of fresh air would be to have the inlet opening nearest to the house side of the drain-trap on the ground level, the more distant one, or the outlet one, alone being carried above the house. So also, the sewer itself is ventilated by means of a pipe carried up above the house. Whatever advantages attach to this system, it could not be enforced here under the Public Health Act, which limits any regulations as to ventilation &c. to house drains, the public sewers not being included.

THE PROPOSED NEWBURY DISTRICT HOSPITAL.

At a meeting of the general committee held last week, it was decided to obtain plans for a hospital of eight beds, allowing 1200 cubic feet for each patient, with provision for an extension to twelve beds.

THE CHOLERA EPIDEMIC.

CHOLERA still clings with much tenacity to Naples and to Spezia, both of them towns where the sanitary circumstances are eminently favourable to the extension of a disease which finds its principal means of diffusion in conditions of excremental pollution. At Naples the diminution in the fatality, which commenced some ten days ago, is still steadily in progress, the more recent records showing that about 150 deaths take place daily. In Spezia the severity of the epidemic is liable to considerable fluctuations. Thus, on the 18th inst. the deaths were nine in number, next day they rose to thirty, now again they are reduced to seven and nine a day. In the other parts of Italy previously infected no material outburst has taken place, but the diffusion of the disease in the province of Naples is considerable, and a fresh province—namely, that of Ascoli, is now reported as infected. At Rome another case has occurred, but it may be hoped that the means of isolation and other measures available will prevent any extension of the disease. In France the epidemic is more quiescent; a few deaths occur almost daily in Toulon and Marseilles, and at Perpignan, where the largest mortality is now maintained, five deaths a day are not unusual. As regards Spain, the contradictory statements as to whether cholera is really prevalent or not are still maintained, but it is quite certain that the Government feel no hesitation upon the point, for they daily record the cholera deaths in the province of Alicante, and now also in that of Tarragona, and they maintain by means of the troops a sanitary cordon round the places that are infected. The extension of the disease into the province of Tarragona has taken place notwithstanding the cordon. On the subject of land quarantines it is noteworthy that Dr. Proust, the chief French sanitary inspector, has reported that the extensions of cholera which have taken place, both into Italy and Spain, of themselves suffice to show that quarantines in populous districts are not only useless but that they become centres from which the disease diffuses itself. He now advocates, in the place of these effete measures, the rigorous enforcement of measures of public health, coupled with proper medical inspection at certain centres along the principal lines of human traffic.

QUARANTINE AND INFECTED PORTS.

At Gibraltar quarantine on vessels arriving from Italy is extended from seven to fourteen days, and all vessels arriving from Indian ports are subjected to twenty-four hours' quarantine. All arrivals from Spanish ports are subjected to a quarantine of fourteen days, and all arrivals from the Mediterranean ports of Spain are ordered to quit Gibraltar.

Vessels from Naples are subjected to ten days' quarantine, in the rest of the continental littoral of Italy.

Quarantine at the frontier of Italy, in the provinces of Turin, Cuneo, and Port Maurizio is abolished.

In Greece vessels from Tunis are subjected to a quarantine of five days' observation.

Vessels arriving from Spanish ports are refused admittance in ports of Morocco. The same regulation is still maintained as regards vessels arriving from France, Italy, and Algeria.

From Nice it is reported that the quarantine at the Var for passengers arriving at that town from the East has been abolished.

At Malta passengers coming from England are to make, before embarking, a statutory declaration that they have not been during twenty-one days immediately preceding their departure from England in any district on the Continent infected by cholera. This declaration must be produced on arrival at Malta, otherwise passengers will not be allowed to land and the vessel will be kept in quarantine. The infected districts are Italy, Spain, and France south of Lyons. Arrivals from French and Spanish ports in the Atlantic will be subjected to twenty-one days' quarantine. Arrivals from ports beyond the Suez Canal are admitted to pratique, provided no passengers or merchandise have been shipped at any ports in Egypt, in the Red Sea, or the Mediterranean.

At Pernambuco vessels arriving from Europe are subjected to quarantine ranging in length from twenty-four hours to ten days.

At Odessa and other Black Sea and Sea of Azoff ports,

Digitized by Google

quarantine of fourteen days is imposed on vessels arriving from Gibraltar. The quarantine in Algeria on arrivals from France has been reduced from seven to five full days.

At Constantinople ten days' quarantine has been applied to arrivals from the Spanish Mediterranean shore, in the same manner as to arrivals from France and Italy. Arrivals from Tunis have to perform five days' quarantine at Turkish ports.

WILLS OF MEDICAL MEN.

THE will of William Parker, M.D., formerly of 25, Palmeira-square, Hove, Sussex, but late of 37, Pulteney-street, Bath, who died on July 13th last, was proved on the 22nd ult. by Mrs. Eleanor Parker, the widow, one of the executors, the value of the personal estate exceeding £4400. The testator gives, devises, and bequeaths all his real and personal estate to his wife absolutely.

The will and codicil of Job Lockyer Seale, M.D., late of Ashton House, Steeple Ashton, Wilts, who died on July 17th last, were proved on the 3rd inst. by the Rev. Frederick Samuel Seale, the son, one of the executors, the value of the personal estate being over £4300. The testator bequeaths certain household furniture and effects, and an annuity of £130 for life or widowhood, to his wife Mrs. Marianne Seale; and remainder of his furniture and effects to his said son. The residue of his property is to be divided between his son's children.

The will of Mr. Frederick William Harris, retired Surgeon-Major Bombay Army, formerly of Leigh Lodge, Leigh, Worcestershire, but late of Buckingham Lodge, Vansittart-road, Torquay, who died on the 7th ult., was proved on the 1st inst. by Mrs. Kate Harris, the widow and sole executrix, the value of the personal estate exceeding £2300. The testator gives, devises, and bequeaths all his real and personal estate to his wife for her own absolute use and benefit.

The will of Donald Cochrane Campbell, M.D., late of Warley, Essex, who died on the 8th ult., was proved on the 10th inst. by Mr. James William Copland, the acting executor, the value of the personal estate exceeding £2500. The testator bequeaths £100 and all his effects, horses and carriages, to his wife, Mrs. Jessie Euphemia Campbell. The residue of his real and personal estate is to be held upon trust for his wife for life and then for his children.

The will of Mr. Thomas Wallis McDonald, Inspector General of Hospitals, R.N., late of Teignmouth, Devon, who died on April 1st last, was proved at the Exeter district registry, on the 28th ult., by Mrs. Louisa McDonald, the widow and sole executrix, to whom he devises and bequeaths all his real and personal estate. The personal estate exceeds £580.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. Edwin Cox, late of 11, Rochester-terrace, Kentish-town, £500 each to the Royal Free Hospital, the City of London Truss Society, the Hospital for Consumption and Diseases of the Chest at Brompton, the Cancer Hospital, Middlesex Hospital, Westminster Hospital, Charing-cross Hospital, and St. Mary's Hospital.—Mrs. Rebecca Gray, widow of John Charles Gray, late of the Strand and of Windsor, Berks, £1000 to the Charing-cross Hospital.—Mr. William James Patterson, late of Carlton-crescent, Southampton, £1000 to the Royal South Hants Infirmary; £5000 to the executive body of the same Infirmary to be called "the Patterson Chaplain Fund," the income to be appropriated as a stipend for a chaplain, who is to be a member of the established Episcopal Church of England, and a graduate of one of the universities of Oxford or Cambridge; £500 to the Southampton Dispensary and Humane Institution; £250 each to the Royal Hospital for Incurables, Putney, and the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, and £150 each to St. Mary's Cottage Hospital, Southampton, and the Sanatorium, Bournemouth.—Mr. J. J. Crosthwaite, £300 to St. Michael's Hospital, £100 to the Children's Hospital, and £100 to the Hospital for Incurables.—The late Mr. John Walker (Preston), £2000 to the Preston Infirmary.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Sanitary State of Gateshead, by Dr. BARRY.[1]—A voluminous report has been issued by Dr. Barry on the sanitary state of the borough of Gateshead, and on the prevalence of infectious diseases in the district. After describing the district generally, as also from a topographical and geological point of view, Dr. Barry enters into details as to the streets and dwellings. Some description of the state of Gateshead, as given by the commissioners who reported on cholera there in 1854, shows that at that date the poorer parts of the town were built back-to-back, or that the back yards between them were so small that they served for little else than the reception of accumulations of filth, that the narrow streets were habitually dark, damp, and unwholesome, and that they often constituted culs-de-sac; or that narrow courts and entries were made to abut on undrained banks of a clayey soil. To all this was added what so usually follows on house accommodation of this sort—namely, overcrowding, filthy habits, and disease. Alterations and improvements have been made since that date, but it is still possible to report that there are districts where somewhat similar defects of house arrangements exist, the insanitary conditions being aggravated by the number and the size of the filth receptacles in the yards. A large number of houses are divided off into what we call tenement houses, and these are at times situated around unpaved or badly paved yards, into which slops are apparently thrown quite regardless of the position of the slop-sink, and consequently the ground is habitually sodden with filth. What is especially needed in Gateshead is action under the Artisans and Labourers' Dwellings Acts of 1875 to 1882, and the enforcement of proper bye-laws as to tenement houses under Section 90 of the Public Health Act, 1875. The details given by Dr. Barry as to individual tenements are worthy of the notice of the Royal Commission on the Dwellings of the Poor. Thus of Riley's house it is said:—"Single room, ground floor; capacity, 1720 cubic feet; six inmates, 286 cubic feet per head; condition, filthy and wretched in the extreme; typhus prevalent. The room above inhabited by another family, no furniture except a broken chair and a small straw heap in one corner covered with a ragged quilt; typhus also." As regards Murray's yard a long description is given, and of the second storey it is explained that it is let off into two-roomed and one-roomed tenements; the third floor is similar, and the excrement and filth of the families in the upper rooms are kept in buckets in cupboards till full, and then emptied into the midden. Several cases of typhus prevailed here in 1882. The general arrangements for the disposal of excrement and refuse are unsatisfactory as regards the poorer classes, and the bye-laws relating to this subject are, as so often is the case, such as to maintain and perpetuate the evils which need remedy. Thus, instead of limiting the capacity of ashpits and middens by some maximum size which none shall exceed, the bye-law as to this says that they shall not be *less* than a specified size, the result being that huge receptacles for filth can be constructed in the midst of human dwellings. The conditions of the sewers and water-supply are next entered into in much detail, and then follows an elaborate account of the mortality statistics. The population is estimated at 69,620 in 1883, the mean mortality for the ten years ending 1880 amounts to 26·1 per 1000, as opposed to 24·0 and 21·4 for the twenty large towns, and for England as a whole, respectively, and the excess is shown to have been mainly due to the epidemic prevalence of one or other of the infectious fevers; small-pox, scarlatina, "fever," and also diarrhœa having largely contributed to it. All this is clearly set out in a series of tables; and then reference is made to certain recent prevalences of typhus and small-pox, which were the immediate causes of the inquiry which has been

[1] To be purchased of Knight and Co., 90, Fleet-street; Shaw and Sons, Fetter-lane; Hadden, Best, and Co., West Harding-street; and P. S. King and Son, King-street, Westminster.

Digitized by Google

instituted. As regards the small-pox, it is worthy of note that whilst the actual number of cases of small-pox was larger in the districts where there was overcrowding and bad house accommodation, yet the proportion of fatal cases to persons attacked was highest amongst the well-to-do; and Dr. Barry is inclined to attribute this difference, to some extent, to the fact that whilst in the poorer parts of the town the vaccination is almost exclusively performed by the public vaccinator, whose work is unexceptionable in quality, in the better-class districts the vaccination is almost entirely performed by the private medical man, in which case regret is expressed that it was frequently of a very imperfect character. This same condition has, in one of Dr. Buchanan's recent reports, been also referred to in connexion with vaccination in the metropolis. The mean age of persons attacked with small-pox in Gateshead was 19·4 years amongst the vaccinated and 8·9 years amongst the unvaccinated, by far the greater proportion of attacks amongst the latter class being in children under five years, whereas amongst the vaccinated no case occurred under one year, and no appreciable prevalence occurred until ten years were reached. The report next goes into a lengthened description of the hospital provision available, pointing to some serious defects which were associated with the early history of the infectious buildings. The report is further illustrated by a series of lithographs, showing the arrangement of houses, &c., and it may be taken as a type of a complete report on the general sanitary circumstances and administration of a large and populous borough. A series of recommendations, suggesting the sort of action which is needed in the future, is appended to it.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

During the week ending the 20th inst., 5732 births and 3518 deaths were registered in twenty-eight of the largest English towns. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 25·6 to 21·4 per 1000, further fell last week to 21·0. During the first twelve weeks of the current quarter the death-rate in these towns averaged 23·1 per 1000, against 20·6 and 20·0 in the corresponding periods of 1882 and 1883. The lowest rates last week in these towns were 14·9 in Portsmouth, 16·6 in Brighton, 17·1 in London, and 17·2 in Birkenhead. The rates ranged upwards in the other towns to 28·3 in Blackburn, 28·3 in Preston, 28·8 in Salford, and 29·9 in Leicester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the four previous weeks from 1314 to 802, further fell last week to 715; these included 413 from diarrhœal diseases, 91 from "fever" (principally enteric), 83 from scarlet fever, 52 from whooping-cough, 41 from measles, 29 from diphtheria, and 7 from small-pox. These diseases caused the lowest death-rates in Plymouth, Halifax, and Portsmouth, and the highest in Sheffield, Sunderland, and Hull. The highest rates of mortality from diarrhœa were recorded in Sunderland, Hull, and Leicester; from scarlet fever in Sheffield and Cardiff; from measles in Birkenhead and Bolton; and from "fever" in Preston, Hull, and Sunderland. The 29 deaths from diphtheria in the twenty-eight towns included 21 in London and 3 in Liverpool. Small-pox caused 6 deaths in London and 1 in Sheffield. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had steadily declined in the ten preceding weeks from 1368 to 477, further fell to 471 on Saturday last; the new cases admitted were 65, against 77 and 66 in the two previous weeks. The Highgate Small-pox Hospital contained 26 patients on Saturday last, one new case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 167 and 170 in the two preceding weeks, declined last week to 159, and were 51 below the average. The causes of 84, or 2·4 per cent., of the 3518 deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Wolverhampton, Leicester, and in four smaller towns. The largest proportions of uncertified deaths were recorded in Huddersfield, Leeds, Sunderland, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which in the two preceding weeks had been 20·5 and 21·5 per 1000, declined to 20·8 in the week ending the 20th inst., and was slightly below the mean rate during the same period in the twenty-eight large English towns. In the Scotch towns the rates last week ranged from 11·8 and 12·2 in Perth and Greenock to 23·6 in Glasgow and 24·1 in Paisley. The 503 deaths in the Scotch towns included 51 which were referred to diarrhœal diseases, 23 to whooping-cough, 20 to diphtheria, 15 to "fever," 14 to scarlet fever, 7 to measles, and not one to small-pox; in all, 130 deaths resulted from these principal zymotic diseases, against 127 and 118 in the two preceding weeks. These 130 deaths were equal to an annual rate of 5·4 per 1000, which was 1·1 above the average rate from the same diseases last week in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 55 in each of the two preceding weeks, declined to 51, and included 24 in Glasgow and 12 in Dundee. The 23 deaths from whooping-cough showed a slight increase upon recent weekly numbers; 10 occurred in Glasgow, 4 in Edinburgh, 4 in Dundee, and 4 in Aberdeen. The 20 fatal cases of diphtheria showed a considerable increase, and included 11 in Glasgow and 4 in Dundee. The deaths from "fever," which had been 9 and 10 in the two previous weeks, further rose to 15 last week, of which 12 were returned in Glasgow. The 14 fatal cases of fever included 11 in Glasgow, where 5 of the 7 deaths from measles were also recorded. The deaths referred to acute diseases of the respiratory organs in the eight Scotch towns showed a decline of 10 from the number in the preceding week, and were considerably below those returned in the corresponding week of last year. The causes of 78, or nearly 16 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 29·3 and 29·4 per 1000 in the two preceding weeks, declined to 26·6 in the week ending the 20th inst. During the first twelve weeks of the current quarter the death-rate in the city averaged 25·0 per 1000, the rate during the same period being 21·3 in London and 16·8 in Edinburgh. The 179 deaths in Dublin last week showed a decline of 19 from the number in the previous week, and included 32 which were referred to the principal zymotic diseases, against 42 in each of the two preceding weeks; of these, 21 resulted from diarrhœal diseases, 5 from scarlet fever, 4 from whooping-cough, 1 from diphtheria, 1 from "fever," and not one either from small-pox or measles. These 32 deaths were equal to an annual rate of 4·8 per 1000, the rate from the same diseases being 2·7 in London and 4·0 in Edinburgh. The fatal cases of diarrhœa, which had declined in the three previous weeks from 48 to 24, further fell last week to 21. The deaths from scarlet fever, which had been 7 and 11 in the two preceding weeks, declined to 5 last week. The 4 fatal cases of whooping-cough exceeded by 3 the number in the previous week, while those of "fever" showed a decline. Three inquest cases and 4 deaths from violence were registered in the city during the week, and 39 deaths occurred in public institutions. The deaths of infants showed a marked increase, while those of elderly persons were considerably below those recorded in recent weeks. The causes of 47, or more than 26 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ARMY MEDICAL DEPARTMENT.—Deputy Surgeon-General Thomas John Murphy, M.D., is granted retired pay, with the honorary rank of Surgeon-General; Brigade-Surgeon Fitzgerald Edward Scanlan is granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major James d'Altera is granted retired pay, with the honorary rank of Brigade Surgeon; Brigade Surgeon George Faught to be Deputy Surgeon-General, vice Francis Holton, M.B., retired upon temporary half-pay; Surgeon Patrick Joseph Gallwey, M.D., has resigned his commission.

ADMIRALTY.—Fleet Surgeon Alexander McDonald, M.D., has been placed on the retired list of his rank.

The following appointments have been made:—Staff Sur-

Digitized by Google

geon Bernard Renshaw, to the *Boscawen*; Surgeon Herbert E. Marsh, to the *Alexandra*, additional; Surgeon John Brunt, to the Royal Marine Artillery at Eastney; Surgeon John J. O'Doherty to be Surgeon and Agent at Cushenden and Cushendall.

RIFLE VOLUNTEERS.—3rd Hampshire: Surgeon and Honorary Surgeon-Major John Robert Kealy, M.D., resigns his commission; is also permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement. —1st Suffolk: Pryce Jones Langford Morris, Gent., to be Acting Surgeon.

Correspondence.

"Audi alteram partem."

THE ALLEGED CAUSE OF CHOLERA.

To the Editor of THE LANCET.

SIR,—There is a subtle danger involved in the assumption of some hypothesis or doctrine at the outset of an inquiry, on account of the influence which it insensibly exerts in systematising the facts so as to harmonise with the assumption. The impressions derived by those who have an opportunity of registering and considering all the facts connected with the progress of an epidemic, and of comparing one epidemic with another, are necessarily different from those of a local, a clinical, or a pathological observer. It is quite true that the investigations of the latter are more likely to be accurate, because their restricted nature allows of their being indirectively and exhaustively made. In speaking of the need for the exercise of caution before concluding that cholera infection through the medium of a specifically contaminated water-supply had yet been demonstrated, it is scarcely necessary to add that no sane man doubts the great importance of a pure water-supply. Of course, if there be a specific germ or cause it will probably be present in water, but it is, and must be, very difficult to prove it, for a population exposed to the risk of drinking dirty water is commonly living under all the other conditions rendering it susceptible to epidemic disease. Practically, life assurance offices are little, if at all, affected by cholera risks, the classes who effect life assurances not being usually those who reside in cholera localities. Have we, in reality, any evidence to show that the use of an impure water would prove more injurious than the use of some saline purgative during the prevalence of cholera? In studying cholera, it should be borne in mind that so-called sporadic cases, an outbreak of limited extent, cholera on shipboard, in a regiment on the march, and an epidemic, whilst so many separate manifestations of one and the same disease, are otherwise distinct things, each having its own history and significance. On all these points I know of no work except Bryden's which gives any foothold of facts; and it was probably due to his intimate acquaintance with these that he was so often enabled, as he certainly was, to make his forecasts of events.

In the Bengal Presidency it frequently happens that, west of the eightieth degree of east longitude, individual cases of cholera in the last quarter of the year precede the appearance of the disease in the following spring; and a bad cholera in spring is often, as a matter of experience, found to be followed by a worse one during the monsoon; but it does not at all follow that the outbreaks should subsequently occur at the same stations as those in which the individual cases had appeared. In 1875 cases of cholera occurred almost simultaneously at the hill stations of Dharmsala, Simla, and Kasauli, and at the same time as in the Deccan and the Berars. The percentage of villages or stations attacked in a given epidemic area is relatively small; attempts to prove that cholera has, as an epidemic, radiated from any given outbreak as a common centre have failed, and it is a matter of observation that it does not retrograde. In other words, it does not proceed at all equally in all directions, neither does it happen that a place or district which has been heavily visited one season suffers disproportionately the next; on the contrary, it generally escapes. Of course, several reasons might be assigned for this, that by Pettenkofer, for example.

In the second Afghan War (1879), while the cholera may be said to have ceased in India in September, it was still prevailing beyond the Indus, in the Khyber and Kurram routes, even up to October, having penetrated as far as Cabul itself in the preceding July. The troops returning from Afghanistan to India in the first week of June actually marched into the cholera, which was advancing to the north. The heat was terrible (110° to 115° F. in the shade), and their sufferings and exhaustion great from this and dust storms. Their losses from cholera were severe, and the disease in at least one of the corps did not disappear for some time, in spite of frequent changes of camps and water-supply. I never heard that this body of troops lighted up an epidemic or an outbreak in the stations through which they passed, which they would certainly have had the credit of having done had they been going in the opposite direction—viz., to Cabul, instead of to India.

The experience at Meean Meer, in the summer of 1881, was interesting in indicating the effect of locality; for the troops were moved out from that station in consequence of cholera amongst them, lost it after a few days, returned, were again affected, and went into camp the second time with a similarly successful result. What cholera has done before it will commonly do again, and once the disease has appeared in Lahore and Meean Meer as part of an epidemic, it may be expected to continue from time to time up to the end of September.

That there should be certain localities which resist the development of cholera in spite of the frequency and the extent of their communications is sufficient to indicate that the transmissibility of that disease is subordinated to some complex influences. The Hurdwar pilgrims carried cholera with them into Mooltan in 1867, and as Mooltan had become a great railway terminus, it was alleged that its immunity from cholera—an immunity lasting over half a century—would be destroyed. But from 1868 to 1875, out of a population exceeding a million in Mooltan, Mozuffargarh and Dera Ghazi Khan, the districts tapped by railway communications, only seventeen deaths from cholera were registered, notwithstanding that the Punjab had suffered from no less than three epidemics during that interval. And I believe that, to come nearer home, Lyons in France, and Birmingham in England, have manifested a similar insusceptibility.

The cholera of 1883 in Egypt began at Damietta, and advanced in a pretty straight line to Cairo in the direction of the prevailing wind, all the places attacked having severally gone through much the same series of phenomena in pretty nearly the same period of time. It did not retrograde, neither did it spread to Europe, although opportunities for its doing so were not wanting. From the same facts different inferences were drawn by different observers: one set holding that it spread along the line of human intercourse, and, directly or indirectly, by it; the other, that as cholera can only manifest itself in the human organism, that is exactly what it should be expected to have done, if human beings are the reagent rendering the presence of cholera manifest. It may be true, of course, that some cholera germ or virus multiplies enormously in the human body, and is disseminated by it. It is quite right that cholera should be studied like any branch of natural history or micro-parasitic pathology; but it seems necessary to assume the existence of bacillus germs or resting-spores, capable of movement by the wind and of resistance to heat, to explain all the phenomena. There may, however, be another aspect of the question. The cause of cholera may be attributable to a condition or quality of matter rather than to matter itself; and it would be easy though unprofitable to cite in illustration the action of magnetism on iron, or what is known as catalysis. We know the influence of locality in which cholera is present, and, for all we know, human beings may (if the apparent paradox be pardoned) represent so many pieces of the locality in movement. Such individuals may sicken and die of the disease and impart it to others, but seemingly with relatively slight results unless they happen to be travelling in the direction and at the rate at which some unknown epidemic influence is itself going. I hold that it would be a matter of prudence, at any rate, to divert the course of a cholera-stricken crowd of people from occupied towns and villages. The fact of there being an appreciable interval between the exposure of an individual and his attack (incubation?) is, however, to my mind evidence that the cause is a material one—possibly a vital agent.

We next come to the *Crocodile*, which left Bombay early

Digitized by Google

in April of the present year. It had cases of cholera on board, but no fresh admission for that disease took place after the 20th of April. The affected men had all come from India. The affected and non-affected drank the same water, and the men of the Army Hospital Corps who were embarked from Malta to attend on the sick did not take the disease. All the passengers and their baggage were disembarked in this country and scattered to their several destinations without any alleged introduction or appearance of cholera anywhere, so far as I am aware.

There is no need to enter into the subsequent events at Toulon and Marseilles. It is possible that some fresh light may be thrown on the history of those events, but, so far as I can ascertain, there are several facts that cannot be reconciled with the assumption that the *Sarthe* introduced the disease into Toulon; and even if she did, it is not easy to see, considering the long interval that had elapsed between the date of the cholera cases on board and the occurrence of those at Toulon, how any practicable quarantine measures could have prevented it. Later accounts state that at Marseilles some fatal cases of malignant cholera occurred last year, and some persons had been attacked this year before the first case at Toulon was reported.

There is one point which requires observation, and that is the frequency with which the inmates of hospitals are first attacked at a station, for this is a fact that arrested the attention of the present Director-General and myself whilst we were in India. The patients were under treatment for ordinary diseases, and had not been admitted for diarrhœa. Possibly the continuous occupation of the wards of a hospital, as compared with other buildings, may afford an explanation. When cholera is present as an epidemic, people may be said to be in a state of unstable equilibrium, and in the case of attendants on the cholera sick I should expect that the depression arising from confinement in a hospital, and the loss of exercise and of sleep, would have an injurious influence.

The 1884 epidemic in Europe is, to my mind, but part and parcel of that of 1883 in Egypt, as that was probably part of a movement from India, and, so far, the western limit of the same epidemic is the affected portions of the continent of Europe. Cholera, as a rule, invades the Central Provinces of India from the east. But in 1882 there was no invasion from that quarter; on the contrary, the disease came from the north out of Bengal and passed towards the south-west, rendering it highly probable that the epidemic moved in this direction towards the seaboard of Bombay, in which city the deaths had fallen in 1882 to 169. At the time that cholera appeared in Egypt, however, there was a large increase, for in the three months July, August, and September, when so many died in Egypt, there were 821 cholera deaths in Bombay city. Meantime there have been some cases of so-called *cholera nostras* in this country, which, in their clinical features, were so apparently identical with cholera as seen elsewhere that in an epidemic they would have been unhesitatingly identified with it.

I desired to have added some remarks in regard to the average duration of a typical outbreak of cholera under different circumstances, and as to the measures which should be adopted when cholera is present or threatening, such as are justified or indicated by experience; but to do this would be to extend this communication to interminable length, and I fear the patience of your readers has been already exhausted.

I am, Sir, yours truly,

J. A. MARSTON,
Deputy-Surgeon General, A.M.D.

September, 1884.

THE UNCERTAIN COMPOSITION AND ACTION OF GREY POWDER.

To the Editor of THE LANCET.

SIR,—Grey powder—hydrargyrum cum creta—is generally believed to be one of the mildest of the preparations of mercury, and as such it is often prescribed for infants and young children, its composition being supposed to be one part of metallic mercury to two of chalk. For many years I have entirely ceased to prescribe that preparation, and, with your permission, I will briefly state my reasons for discontinuing its employment. When I was in the habit of using it, I found its operation to be most uncertain and variable; at one time its action was mild, while at another it caused severe pain, vomiting, and purging. My mistrust of it was finally confirmed by a conversation which I had many years ago with Professor Redwood of the Pharmaceutical Society. The professor told me that in consequence of having heard frequent complaints of the uncertain and often violent action of the drug, he had analysed a number of specimens, and the result was that all, or nearly all, were found to contain a variable proportion of the two oxides of mercury. The last number of the *Pharmaceutical Journal* (Sept. 20th, p. 230) contains an interesting report and discussion on the strength and condition of commercial specimens of hydrargyrum cum creta and other mercurial preparations. Out of twelve specimens of grey powder analysed, not one was found free from the oxides of mercury. One sample contained as much as 2·2 per cent. of mercurous oxide and 4·67 of mercuric oxide; and another had 6·15 of mercurous oxide with 2·8 of mercuric oxide. The presence of so large a percentage of the oxides of mercury explains the occasional violent action of the drug. The mercuric oxide meeting with hydrochloric acid in the stomach would be at once converted into the poisonous perchloride.

From the discussion which followed the reading of the paper it would appear that the variable proportion of the oxidised mercury depends, not upon the manner in which the ingredients are rubbed together, whether by hand, with a mortar and pestle, or by steam-driven machinery, but upon the length of time during which the drug has been exposed to the air after its preparation; so that, while a freshly prepared specimen might contain no oxidised mercury "in a month," as Mr. Tyrer, a manufacturer, said, "a difference would be perceptible, in three months still more, and so on until a point was reached when the oxidation ended, though what that point was he was not prepared to say."

My object in this communication is to direct the attention of the profession to the uncertain composition and operation of this commonly employed drug, and especially to point to the occasionally distressing results of its administration to young children.

Many years ago, during a consultation with Sir Benjamin Brodie, he asked me how I would treat syphilis in an infant. I replied, "With grey powder;" upon which he said, "And the result would be that you would gripe and purge your patient to death."

I am, Sir, yours truly,

Savile-row, Sept. 22nd, 1884. GEORGE JOHNSON.

THE CHOLERA FUNGUS AND SULPHUR TREATMENT.

To the Editor of THE LANCET.

SIR,—At the International Medical Congress, Tommasi Crudeli (Rome), in his paper on Cholera, mentioned that æthiops mineralis had been used in Italy for the treatment of cholera, thus supporting Pacini's view that cholera was dependent on a fungoid organism. I am sure it will interest Dr. Crudeli to know that sulphur was employed in 1847-48 as a remedy in epidemic cholera by Dr. John Grove, the father of the germ theory. Grove published his observations in a pamphlet, entitled "Sulphur as a Remedy in Epidemic Cholera," published by Ridgway. He believed that cholera was caused by a fungus, and in THE LANCET, 1849, pp. 427, 451, are to be found two articles by him, headed "The Vitality of the Cholera Fungi Demonstrated." In the same journal, at p. 428, vol. ii., 1849, are some drawings of this fungus, which Grove believed to be the cause of cholera. They are rudely drawn, and are, I believe, torulæ. There are some comma-shaped bodies which cannot be so classed. Dr. B. Ward Richardson has declared that Grove was the first in modern times to advocate the hypothesis that living germs were the exciting agents of epidemic and infectious diseases.[1] He was evidently in advance of his time. In a letter to me, Nov. 5th, 1881, Dr. Grove wrote: "The only merit that I can claim for my work is that I endeavoured to lay a foundation for more definite ideas as to the nature of morbid agencies on the vegetable as well as the animal kingdoms, and to suggest remedies, as sulphur for cholera, acetic acid for typhoid fever." Pacini's and Koch's observations prove that Grove was on the right track. Some other names deserve to be added to that of Dr. Grove in relation to the fungoid causation of cholera—viz., Dr.

Brittan, who condensed the air of rooms in which cholera patients had died, and detected cholera cells, Dr. Swayne, Dr. Cowdel, Dr. Mitchell (Philadelphia), and Dr. Budd. It would save much discussion as to priority if you would republish the following abstract of Budd's paper, which appeared in THE LANCET, in 1849, vol ii., p. 271. Many of his suggestions stand good at the present time.

Abstract of Dr. Budd's Paper.

"An announcement was lately made by Mr. Brittan of the discovery that peculiar microscopic objects exist constantly in the characteristic rice-water discharges of persons affected with cholera, and in the atmosphere of infected places. The particular objects in question were first seen by two or three members of a committee appointed by the Bristol Medico-Chirurgical Society for the microscopic observation of subjects connected with cholera. The first drawings of them, together with the great variety of other objects generally to be met with in the rice-water discharges, were made by Mr. J. Swayne and Mr. F. Brittan in the second week in June last. These drawings, together with specimens of rice-water, were exhibited at the next meeting of the committee. At that meeting there were present Mr. J. G. Swayne, Dr. Bernard, Mr. Neild, Mr. A. Prichard, and myself. Numerous other drawings of the same kind by Mr. J. G. Swayne and Mr. Brittan were shortly afterwards laid before the Bristol Medico-Chirurgical Society. The laborious observations subsequently made by Mr. Brittan and Mr. Swayne, and laid from time to time without reservation before the Bristol Medico-Chirurgical Society, certainly did much to show that some very important relation existed between these bodies and malignant cholera. Shortly afterwards, and being at the time aware of this discovery, I detected the same organisms in great numbers in almost every specimen of drinking-water which I was enabled to obtain from cholera districts. This led me to examine a great number of specimens of water from healthy quarters, and although I often found in it a good deal of matter of various kinds, organic and other, in no single instance did I see anything resembling the peculiar bodies in question. These considerations and others have led me to the following conclusions:—1. That the cause of malignant cholera is a living organism of distinct species. 2. That this organism, which seems to be of the fungus tribe, is taken, by the act of swallowing, into the intestinal canal, and there becomes infinitely multiplied by the self-propagation which is characteristic of living beings. 3. That the presence and propagation of these organisms in the intestinal canal, and the action they there exert, are the cause of the peculiar flux which is characteristic of malignant cholera, and which, taken with its consequences, immediate and remote, constitute the disease. 4. That the new organisms are developed only in the human intestine. 5. That these organisms are disseminated through society: first, in the air, in the form of impalpable particles; secondly, in contact with articles of food; and thirdly and principally, in the drinking-water of infected places. 6. That these organisms may probably be preserved for a long time in the air with their powers unimpaired, but that in water, which is doubtless the chief vehicle for their diffusion, they soon undergo decay; and, moreover, sharing in this the common fate of their tribe, become the prey of beings of a higher order."

The conclusions taken together enable us to account for all the chief phenomena of the disease. They lead, besides, to practical references of the utmost importance. By acting upon this knowledge now, although we may not be able to stay the plague, we may yet much abridge its sojourn among us. The means by which the mitigation may be accomplished are obvious. The objects they include are two-fold:—1. To destroy from this time forward all the poison which continues to be generated in the bodies of infected persons; and (2) to prevent, as far as possible, the poison which has already escaped from us from taking effect. The first of these objects may be attained by the simplest means. All that is required, in fact, is to receive henceforth the discharges from the sick into some chemical fluid known to be fatal to beings of the fungus tribe. Nothing more is necessary than to choose among these agents the cheapest and the most convenient. I content myself merely with suggesting that the solution of chloride of zinc possesses strong recommendations, if it should be found, as I believe it would, effectual for the end in view. The second object, that of preventing the poison which has already been cast loose from taking effect, is more difficult to accomplish. But for this, too, a great deal may be done. As water is the principal channel through which this poison finds its way into the human body, a fact already established by the researches of Dr. Snow, and of the discovery of which he must have the whole merit, so is the procuring pure water for drink the first and most effectual means of preventing its action. From this day forward let the people of infected districts be supplied with water from healthy quarters or from sources beyond the reach of contamination; and if this be not feasible, let steps be taken to rid the water they are compelled to drink of the deadly poison it holds. This might be done by very simple means. It is probable even that the act of boiling water would suffice; but if boiling the water should not succeed, it might be distilled. To no part of the comunity is the need of an immediate supply of pure water more urgent than to the immense floating population of the port of London. The importance of preventing the disease in sailors will be more apparent when we reflect on the unquestionable fact that ships are great instruments for its diffusion.

I am, Sir, yours truly,

Halifax, Sept. 19th, 1884. T. M. DOLAN, M.D.

BICYCLE RIDING AND PERINEAL PRESSURE: THEIR EFFECT UPON THE YOUNG.

To the Editor of THE LANCET.

SIR,—I have read with great interest the article with the above heading in your issue of last week, by Dr. Strahan. I quite agree with everything that he has said, and am even prepared to go further than he has done, and to assert that bicycle and trycicle riding will produce stricture of the urethra.

During the last year I have had two cases under my care which were distinctly traceable to the effects of continuous riding on such a saddle as that described by Dr. Strahan. The first case came under my notice in January last, the patient being eighteen years of age. He had been racing for the last twelve months, more or less. He never had gonorrhœa, nor had he practised masturbation. Normal calibre of urethra 32 min.; dense stricture defined by No. 17 bulb at 4½ in. from meatus. The second case consulted me about the end of March. He was a middle-aged man, who had taken to tricycling for about three years before I saw him. He came to me complaining of perineal pain and difficulty of micturition. In this case the stricture was accompanied by an enlarged and tender prostate. Normal calibre of urethra 30 min.; stricture of 15 min. at 5 in. from meatus. Both these cases were treated by internal urethrotomy, and made satisfactory recoveries. It appears to me that the stricture produced by cycling approaches very nearly in character to a traumatic stricture, and good results can only be obtained by cutting. I think it possible that the bicycle saddle could be so constructed as to throw the weight only upon the tuberosities of the ischia. If this could be managed, one of the greatest objections to a most healthful form of exercise would be removed. As it is, however, with the saddle now in use, I am afraid that the present generation of surgeons will find a lamentable increase in the number of these stricture cases.

I am, Sir, yours truly,

GEORGE HERSCHELL, M.D. Lond.

Moorgate-street, E.C., Sept. 22nd, 1884.

To the Editor of THE LANCET.

SIR,—Allow me to ask Dr. Strahan, through the medium of your valuable journal, if he, during the last ten years of his professional career, has met with a single case of perineal mischief, either in young or old riders, the direct effect of bicycle or tricycle (with saddle) riding? If so, I shall be glad to hear of such. I have carefully read Dr. Strahan's interesting paper published in your issue of Sept. 20th, but I must say, with all due respect to that gentleman, that he appears to have imagined certain evils which, as far as I know, have not yet made their appearance from the causes so lucidly described by him. There are many men who have been great cycle riders from the times of the old "dandy horse" to the present period, and who have ridden every kind of machine, from the above to the old "bone-shaker" and its various grades of development, up to the

Digitized by Google

now beautiful, comfortable, and almost perfect machines. Yet although these men have ridden nearly every day for the last thirty or forty years and have often covered long distances in a single day, even on the "bone-shaker" with its hard saddle and rigid spring, they are now living examples of the value of cycling, and are in the enjoyment of remarkably good health, both of mind and body—instance Viscount Sherbrooke, one of the oldest bicycle riders. That the pressure on the perineum, from causing congestion of the prostate, &c., will lead to masturbation and early sexual indulgence is a statement which I am inclined flatly to deny. I maintain that the healthy out-door exercise, the exhilarating movement, the pleasures of companionship, the constant change of scene in bicycle-touring, as well as the healthy rivalry of the race-track, have a tendency to take a young man out of himself, and to induce that condition of mental and physical equilibrium antagonistic to the state of nervous weakness and irritability which leads to sexual abuses. Let anyone look at the members of the various clubs from all parts of the country assembled at some great "meet," and he will at once admit that a finer, healthier-looking, jolly set of young fellows are seldom seen together. Rarely will one detect amongst them the peculiar physiognomy of the masturbator or the sensuous aspect of the indulger in early sexual pleasures. Such individuals usually seek other resorts or avoid the gaze of the crowd.

I have been tempted to write the above remarks, as I think it is a pity that statements should be made which are only theoretical, and which are entirely unsupported by facts, and which are calculated to deter many from taking to the health-giving pleasures of the wheel, and, besides that, to injure an industry which is giving employment to thousands. Trusting you will favour me by the insertion of this letter,

I am, Sir, yours faithfully,

H. A. ALLBUTT, M.R.C.P.E., &c.,
Representative Councillor, Cyclists' Touring Club; Hon. Medical Officer, Leeds Harehills Cycling Club.

Park-square, Leeds, Sept. 23rd, 1884.

OVER-PRESSURE IN SCHOOLS.

To the Editor of THE LANCET.

SIR,—In the instructions to inspectors of schools in England and Wales, issued from the Educational Department of the Government, Sir F. R. Sandford, secretary of the Educational Department, communicates the following official information:—"*Many well-founded complaints have been made of undue pressure on backward scholars by keeping them in after school, by long home lessons, or by an injudicious use of emulation.*" These words have acquired additional significance since the date of their issue, August 9th, 1882, and in the face of the criticisms of this subject in the chief daily journal of the past week. When the secretary of a Government Department makes such an assertion as is here quoted, and this receives confirmation from a consensus of opinion in the medical profession, the subject cannot be readily dismissed in its medical aspect. Either Sir F. R. Sandford must be giving needless instructions to the inspectors of his department and making an exaggerated statement in justification of these instructions, in saying that "*many well-founded complaints have been made of undue pressure,*" or Mr. J. G. Fitch, one of the inspectors of schools, must be in error in throwing doubt on this subject, and must differ greatly in opinion from the secretary of his department, who, presumably in his official capacity, expresses the conjoint opinion of a large majority of inspectors, and the matured conclusions of the chief officers of the Educational Department, as embodied in the words quoted. A general uneasiness is displaying itself in the public mind, which is not likely to be set at rest till some farther reassurance is given that over-pressure is not converting our schools into intellectual forcing houses, to the detriment of the physical and mental constitution of the scholars.

Nor can the bearing of this question be confined to the elementary schools of the country. Private schools, grammar schools, and the higher grade public schools, are all engaged in a great educational struggle, necessitated by the prevailing system of competitive examination for entrance into every intellectual sphere of life. It is quite contrary to the nature of things that such competition should be entered into without the risk of undue effect on the part of some emulous students, and undue pressure on the part of ambitious teachers. While in such a struggle it is only a minority, and perhaps a very small minority, who suffer so much in health as to increase the numbers in our lunatic asylums, or to add to the death-rate from cerebral diseases directly referable to mental strain in early life, yet there may be a very great impairment of mental and physical vigour such as only can be cognisant to and duly estimated by the medical practitioners of the country. Such knowledge scarcely admits of a statistical classification or proof, but the opinion in the profession is weighty enough to justify the belief that there is danger ahead unless some modification of the existing system is adopted having a greater regard for health at the educational period of life. Some impatience will in all probability be manifested by both the managers and the inspectors of elementary schools at the prospect of the introduction of some medical direction and authority on matters of education beyond what has hitherto prevailed; and a still greater impatience on the part of the authorities of the higher institutions of the country may be expected. But in these days of educational struggle some restraining influence is necessary here and there to advise when the more emulous should be checked, to guard against over-pressure of the less intellectual in their struggle for distinction, and to weed out that residuum on which it is a waste of power to attempt to do more than to teach the most elementary subjects in the most elementary way. The general acquiescence by parents and schoolmasters alike in the existence of a necessity for the great educational struggle which prevails to meet the requirements of the modern competitive system places almost beyond the sphere of controversy the question of "over-pressure," voluntary or imposed, in the educational system of the day in every grade of school. Scarcely a practitioner in the country can be devoid of experience of the evil; but the problem remains to be solved how it can be judiciously, yet successfully, met and rectified with no more interference with our national educational system than is absolutely necessary. It is an anomaly in our laws that while the regulation of the physical labour of the young in our factories is subjected to medical supervision, the mental labour at an earlier period of life is not so. The mental strain of the one should have the same protection and regulation as the physical strain of the other.

As a family practitioner my experience is that the school vacation time and the return of pupils to their homes never come round without bringing me some school boys as patients with debility and cachexia, for whom I advise *less work*. During the twenty-four years I was medical officer at Wellington College (sixteen years of which I taught the experimental sciences there, and therefore had some personal insight into the effect of school work on pupils and teachers), I do not remember a term passing in which both boys and masters were not *jaded* by the work of the term, and the examination at the end of it. Boys grew wan and intolerant of discipline, and masters (even the best of men) become irritable and querulous among themselves. What can this be but over-pressure? The vacation passes and both return invigorated. What other duty in life so jades as to make three or four months' rest out of the twelve a necessity? The question naturally arises to the medical mind, can the human brain be subjected to such an educational *over-pressure* and rally sufficiently to leave no permanent traces behind?

I am, Sir, yours truly,

Wokingham, September 25th, 1884. J. G. BARFORD.

LUNACY LAW AGITATION AND SUICIDE.

To the Editor of THE LANCET.

SIR,—Agitation against existing lunacy laws, without the present possibility of substituting any other method of procedure in dealing with persons of unsound mind, is producing its natural results. Members of the medical profession, who do not wish to encounter the possibility of being subjected to harassing and vexatious litigation by complying with the requirements of these laws on behalf of their patients, have in many cases, with the writer of a recent letter in a medical contemporary, made their resolution "they will not sign any certificate for anyone, rich or poor." As a consequence of this resolution the public has, much sooner than could have been anticipated, realised how much greater an evil it is to

Digitized by Google

have numerous persons of unsound mind left at large than for one error in procedure to take place.

On June 28th last you did me the honour to insert a letter, in which I discussed this evil from a social, statistical, medical, and legal point of view, with particular reference to suicidal deaths, and your leading article of the 20th inst. once more directs attention pointedly to the alarmingly increasing number of suicides. These do not appear to be confined to any particular class of society, as reference to the following cases taken from *The Times* of the last few days will show, and some of them seem all the more deplorable because the exercise of unfettered medical skill, combined with prudent care and forethought, would assuredly have prevented such distressing consequences:—Sept. 11th, C. C. drowned himself in the Thames; Sept. 11th, M. A. A. cut his throat with a razor; Sept. 13th, H. W. poisoned himself; Sept. 15th, G. D. drowned himself in a duck pond; Sept. 16th, A. W. C. strangled himself with a leather strap; Sept. 17th, F. W. drowned himself in Hampstead Ponds; Sept. 17th, M. A. M. drowned himself in a tank at the rear of a house; Sept. 18th, P. C. smashed his skull by springing over a staircase; Sept. 18th, P. M. shot himself; Sept. 20th, F. S. cut his throat.

There is little doubt that in the majority of these, and other cases of suicide, the fatal act was induced by an existing condition of melancholia or other form of brain disturbance, the manifestations of which may have been active or passive, accompanied by delusion or hallucination, or otherwise; but still the well-recognised mentally diseased but easily curable condition in the early stages, "melancholia," in which the aspect of everything to the unfortunate sufferer becomes as it never was to him before—completely changed—and life under this infliction becoming "flat, stale, and unprofitable," he hastens, it may be with his diseased condition only as yet imperfectly realised by his relatives, and while still without proper care or treatment, successfully to shake off its trammels.

Compare those results of everyday experience with regard to unsoundness of mind in persons at large, under care at home, or under care as single patients with or without certificates, with the results obtained under recognised and properly constituted care and treatment. Out of a total number of 78,528 persons registered as of unsound mind during the past year, only fourteen succeeded in committing suicide while under such care.

Apologising for the length in which I have already intruded on your valuable space, I would ask you to allow me to conclude this letter in the words of your reviewer of the last report of the Commissioners in Lunacy: "It would be desirable that some record should be made of suicides by insane persons not under certificates. If such cases were reported by the coroners to the commissioners, the latter, it may be predicted, would by investigation obtain some valuable information in regard to the action of the present law of certification in preventing insane persons being placed under proper care." I am, Sir, yours obediently,

Harley-street, W., Sept. 20th, 1884. JAMES ADAM, M.D.

"CHOLERA IN MARSEILLES."

To the Editor of THE LANCET.

SIR,—I notice a letter in your issue of the 20th inst. from Dr. Drysdale, an *officier de santé* of Mentone, in which he tells us that "there were cases of cholera in Marseilles last autumn"; and he at the same time throws some sidelight on the system of *suppressio veri*, which appears to have been in vogue to prevent the fact of the existence of Asiatic cholera leaking out. This tendency, perhaps, is not the sole privilege of Marseilles. However that may be, the following information, gleaned from a conversation I had the other day with a French naval officer who was a fellow-traveller with me on the Paris, Lyons, and Marseilles Railway, might, I venture to think, tend to prove suggestive. He told me, and very frankly, that there were cases of undoubted cholera on board his man-of-war, lying in the harbour of Toulon early this year, at a time, I might recall attention to the fact, when the French press was seized with a sudden frenzy for the imposition of rigorous and irksome, but futile, quarantine on all arrivals from the far East, on account of the prevalence of cholera in Bombay and Egypt. This French war-ship had, albeit, come from Tonquin, where she had been actively engaged in operations, but this, and other unwelcome facts or items of intelligence, were carefully kept in the dark from eagerly inquiring "special" and "own" correspondents of the English press.

Now, whether the comma bacillus of Koch and others be, forsooth, a common or garden bacillus, pure and simple, or a myth, it is but fair to Dr. Koch that the medical press should hold over its verdict till the other side of the question is also before the profession in its present phase. It can scarcely be gainsaid that the sanitary arrangements of Marseilles were, and even are, anything but *sans reproche*, and the same may likewise be pronounced of many of the Italian ports. The obvious indication, therefore, is that the sooner the authorities on the Continent set to work in this direction and discard *in toto* the futile and absurd *fiasco* of quarantine the better would it prove in the interests of the public. Your pictorial contemporary, the *Graphic*, not long since favoured us with some amusing and humorous but telling sketches of how quarantine, fumigation, &c., are carried out; and, I think, it would do good if medical artists like Mr. P. Teale ("Dangers to Health: a Pictorial Guide to Domestic Sanitary Defects," J. and A. Churchill, London) were to delineate in like manner all insanitary places as well as the sanitary ones, and exhibit them in some Health Exhibition like the one now open in South Kensington.

I am, Sir, yours very truly,

London, Sept. 22nd, 1884. JOHN C. LUCAS.

MANCHESTER.

(From our own Correspondent.)

THE WATER-SUPPLY AND THE REMOVAL OF NIGHT-SOIL.

As a result of the dry warm summer we have had two important matters connected with public health come prominently into public notice. First, the water-supply appeared to be getting within measurable distance of real scarcity, several of the reservoirs approaching a dangerously low condition, and a great outcry was for a time raised, especially in some parts of the city, as to the quality of the supply. It was stated by numerous correspondents in the newspapers that the water was turbid and ill-smelling, particularly after being boiled, and there certainly seems to have been some foundation for these complaints; but it was apparently the water from one reservoir in particular that was chiefly at fault, the cause of it being, not any unusual contamination, but the low state of the reservoir, and this with a hot sun pouring steadily down on an almost stagnant shallow layer of water had given rise to the conditions complained of. Since the heavy rains of the last two or three weeks all complaints have ceased, and our water-supply is now in its usual satisfactory condition. Another public grievance has, however, called forth loud and bitter complaints. Manchester, as many of your readers are aware, has, during the past ten years, adopted to a very large extent the dry system of earth-closets, removing regularly the night-soil and other refuse of the city to a large depôt situate on the outskirts of the town, where elaborate works and machinery are in operation for converting it into a marketable manure, which has been attended with a very large measure of success. But to remove the enormous mass of material constantly and quickly from so large a population as this necessitates the employment of a large number of waggons to convey the contents of the closets &c. to the above works. Specially constructed pans, with tightly fitting lids, and waggons specially built for the purpose of holding these, are in use, and hitherto have not given rise to much annoyance, but lately the papers have teemed with complaints of the nuisance arising from these carts in passing through the streets and from the removal of the pans during the daytime, and it has been suggested that the work should be done at night instead of being carried on all through the day. At one time it was done at night, but the greatly increased cost and the difficulty of efficiently supervising the men engaged in it, led to the nightwork being abandoned. Probably now that the hot weather has passed by for the present season, we shall hear less of any nuisance being caused. If it be chiefly a matter of cost, this ought not to stand in the way, for although the Health Committee, upon whom this work devolves, is always being reproached as the spending depart-

Digitized by Google

ment *par excellence*, still public opinion is daily advancing in matters relating to sanitary work, and few will complain that money is ill-spent that tends to make our cities and large towns more healthy.

ACCOMMODATION FOR INFECTIOUS DISEASES.

The authorities here have lately been active in providing accommodation for infectious diseases. At the last meeting of the Barton Rural Sanitary Authority plans were submitted for providing a temporary infectious hospital for eight patients, at a cost of £290. The Manchester guardians also had before them plans of a temporary hospital for infectious diseases, which was estimated to cost £2326, and at a meeting of the Salford Guardians sanction was received from the Local Government Board to a proposal to subscribe £500 per annum towards the maintenance of the Salford Borough Fever Hospital. The expediency of this step is, however, doubtful, for it is certainly undesirable to mix the pauper class of patients with these of a better station in life, and will tend to prevent the latter from making that use of these hospitals which is so desirable if anything like isolation of infectious disease is to be attempted; added to which it has but lately been reported that Salford Hospital had not sufficient room for the cases which already come under the notice of the health authorities there.

THE SHIP CANAL SCHEME.

The ship canal scheme, which appeared totally wrecked on its rejection by the Committee of the House of Commons, is showing, if possible, increased vitality, and its promoters are determined to bring it forward again in the next Parliamentary session. In connexion with it there is a question which has not received much public attention—viz., what provision is to be made to prevent the canal and docks in the neighbourhood from becoming a source of nuisance and danger by stagnation of the water, as the flow therein will be of very limited amount, and if any sewage finds its way in a very undesirable state of things may result.

VACANT MEDICAL APPOINTMENTS.

Several important medical appointments have recently fallen vacant here. At St. Mary's Hospital the Resident Obstetric Surgeoncy has been relinquished by Mr. A Winterbottom, after some three years' tenure of office. The posts of Resident Medical Officer and that of Resident Surgical Officer at the Royal Infirmary are both vacant, the former by the unexpected resignation of Dr. Grant, and the latter by the expiration of the appointment of Mr. B. Pollard; Mr. Pollard has held the post of Resident Surgical Officer for the past two years to the satisfaction of all who have the management of the Infirmary, and the Board would fain have retained his services for a longer period if he could have been prevailed on to remain. The above are some of the most valuable and important of provincial hospital resident posts.

LIVERPOOL.

(From our own Correspondent.)

THE NORTHERN HOSPITAL.

THIS hospital was established just fifty years ago, and the present building was erected in 1834, on a site which was then at the north end of the town, but has now become nearly central. It has for years been found wholly inadequate to the increasing demands made upon it, but at present it is impracticable to rebuild it upon its present site or to remove to a new one. As, however, increased accommodation was urgently required for the nursing staff, a new building has been erected on a site closely adjoining the hospital. It is constructed chiefly of galvanised iron lined with varnished pine, approached by a covered bridge, and contains accommodation for twenty-six nurses and the matron. It was opened on the 17th inst. by the Mayoress (Mrs. Holder), and, at the same time, the number of beds in the hospital was increased to 150 by the opening of a new ward. These alterations will prove of immense benefit, but the erection of a new hospital cannot be long deferred.

SMALL-POX EPIDEMIC AND HOSPITAL ACCOMMODATION.

At the last meeting of the Health Committee, held on the 18th inst., it was announced that the temporary small pox hospital erected on the Park Hill estate was now ready. It was resolved that the hospital should be opened for the reception of such patients suffering from small-pox as are now removed under the instruction of the medical officer of health to the workhouse hospitals. There was some opposition to the resolution, which was only carried by a majority of one. Thus the principle contended for in THE LANCET has been practically admitted, and it may be assumed that in future the workhouse hospitals will be reserved for strictly pauper cases. At the same meeting it was stated by the medical officer of health that the death ratio was 24·8 per 1000.

MEDICAL FACULTY, LIVERPOOL UNIVERSITY COLLEGE.

The winter session will commence on Saturday, October 4th; Lord Derby is expected to preside and to distribute the prizes. The success of the students during the past year at the examination was very marked, and, judging by results, the local school of medicine under the new *régime* promises to be more successful than ever. Dr. Waters, having resigned the chair of Physic, is succeeded by Dr. Glynn, who has for some years past been well and favourably known to the students as a most successful clinical lecturer and teacher at the Royal Infirmary, to which he was elected physician fourteen years ago.

CRIMES OF VIOLENCE IN LIVERPOOL.

On the 17th inst. the body of a girl twelve years of age was found floating, perfectly nude, in the Leeds and Liverpool Canal, under circumstances strongly suggestive of criminal violence. On the the 20 h inst. a female brothel-keeper was stabbed in the chest by a Russian seaman, death taking place very shortly. Within the last few months four girls, their ages ranging from seven to fourteen, have been admitted into the Lock Hospital suffering from disease following alleged criminal assaults. Violent assaults on the police are of almost daily occurrence. Whether all these are commensurate with the increase of population or not is doubtful, but that they cause much uneasiness is beyond doubt. In spite of the advance of temperance there is still a fearful amount of drunkenness prevalent here, arising quite as much from the quality as the quantity of drink imbibed. If the adulteration of beer and spirits could be prevented, a reduction would almost certainly take place in crimes of violence, many of the prisoners arrested being drugged as well as drunken.

IRELAND.

(From our own Correspondent.)

THE SANITARY CONGRESS AND EXHIBITION, DUBLIN.

IN a few days the Exhibition and Congress, held under the auspices of the Sanitary Institute of Great Britain, will be open. The former, located in the suburbs, will continue for three weeks, while the Congress will have its meetings in Trinity College, and will last a week. The Exhibition will be formally opened by the Lord Mayor, who has also issued cards for a conversazione to be held at the Mansion House on October 1st. Bands, concerts, flower show, fêtes, illuminations, promenades, and other attractions, will be offered to visitors, and the Exhibition, it is expected, will prove extremely popular. Besides papers by Dr. Cameron and others, Surgeon-General De Renzy will contribute one on the Conditions under which Cholera is Prevalent in Northern India, and Dr. MacCabe, Local Government Board Inspector, on the Water-Supply and Drainage of Small Towns. Surgeon-Major Jones will read a communication on the Insanitary Condition of Small Towns in Ireland, while Dr. Flynn will contribute a paper on the Circumstances attending the Discharge of their Duties by Medical Officers of Health in Ireland. Other subjects will include Ambulance Work, Temporary Hospitals, Isolation, and Ventilation. On October 2nd a public banquet will take place in the Shelbourne Hotel, and on the following Saturday three pleasure trips have been arranged.

DUBLIN HEALTH EXHIBITION HOSPITAL FETE.

In connexion with this Exhibition arrangements are being made for a hospital fête for the benefit of the Dublin city hospitals to be held in the Exhibition on Saturday evening,

Digitized by Google

October 4th. The hospitals which will participate in the amount obtained comprise twelve general and five special hospitals; and it has been arranged that nine-tenths of the net proceeds of the receipts shall be divided in equal proportions among the twelve general hospitals, and one-tenth among the five special hospitals. The committee have appealed to the owners of gardens in the vicinity of Dublin for donations of evergreens and the loan of plants for decorating the hall, and also for cut flowers and bouquets for sale at the fête, or for distribution among the hospitals. His Excellency and the Countess Spencer have signified their intention of being present if possible.

THE LIFFEY.

As the weather gets cooler less complaints are heard about the abominable effluvium which arises from this foul cesspool, but that it is a dreadful nuisance and should not be permitted to exist in the centre of a large city is acknowledged without a dissentient. A correspondent in one of the daily papers has this week made a suggestion which, if adopted, would probably be of service in mitigating, if not entirely removing, the evil. The plan he proposes for cleansing the river is to narrow its passage considerably by the construction of two stout walls of masonry, one on either side from Kingsbridge to Carlisle Bridge, with apertures at various points for discharging sewage, the almost certainty being that through this narrow channel the sweep of the tide would be rapid and sufficiently strong to carry the sewage well down the river, and so prevent any considerable deposit of the filth in the Liffey bed. The river so cleansed should be arched over with tubular iron plates or brickwork, as has been done by the Corporation of Belfast with what was as foul a nuisance as the Liffey, viz., the Blackstaff River. The cost would be very large, but any measure that would abate the evil and promote the health of the citizens should be welcomed.

The salary of the consulting sanitary officer of Lismore Union has been reduced by the guardians from £20 a year to £5.

ITALY.

(From our own Correspondent.)

SCARCELY will the cholera have disappeared when that most characteristic of its sequelæ—controversy—will be fanned into full blast. Already we are having a foretaste of this bequest, the disputants ranging themselves round three groups of questions. First, as to whether or to what extent the comma bacillus of Koch is pathognomonic of cholera; second, as to the hygienic measures best fitted to repel a future visitation, and the order in which these should be commenced; and, third, what remedies or what methods of treatment are most worthy of the serious consideration of the profession in its fight with the actual disease. Unfortunately, there is in all these questions a debatable margin wide enough for any number of controversialists, and, regarding the second in particular—that of hygiene—the phenomena witnessed and attested in Naples are perplexing enough. For example, the narrow, ill-ventilated streets intersecting blocks of buildings in which the population teems like rabbits have been precisely those in which cholera has numbered least victims; while the dwellings which, from their amplitude and situation, the freely aired thoroughfares dividing them, are in marked contrast to the preceding have contributed the heaviest contingent to the hospital and the cemetery. Again, the ill-fed, badly clothed, unwashed inmates of the rookeries have come off very lightly in comparison with the well dieted, comfortably clothed, not uncleanly bourgeoisie. "Partly because by nature," says the correspondent of the *Opinione*, whose letters from Naples have given the best account of the epidemic, "we have something of the Arab, partly because the facts above stated reinforce the sentiment of fatalism which is at the bottom of our southern character, our populace laughs to scorn all the admonitions of the authorities and devours figs, capsicums, tomatoes, more or less unripe, does everything in fact which it has means to indulge in, though forbidden by the profession. As to soup kitchens, it will have none of them; 'these,' it says, 'are for the sick, and we are quite well.'" Another fact is also significant: the troops—including the volunteers of the civil population, who have laboured so heartily in the work of isolating the sick—are now suffering severely from cholera, though every precaution in the matter of food, drink, and sleeping accommodation has been observed on their behalf. Then, as to the hygienic reforms to be effected in Naples, there is one party eager to begin by pulling down the *fondaci* and housing the court-and-cellar population in properly lighted and ventilated apartments; while another party, which has a good deal to say for itself, would commence operations by bringing in pure water in place of the contaminated and insufficient supply apportioned to the city. To carry out the first the drain on the national exchequer will be enormous, insomuch that it is seriously proposed to suspend the undertaking for connecting Rome with Naples by faster trains and to devote the money so economised to the work of rebuilding the ramshackle quarters. New imposts, says the *Opinione*, are what Italians cannot bear, and there is no other way to meet the expense of rehabilitating Naples than by deflecting to that purpose the means set apart for less urgent enterprises. The financial difficulty is always the primary one in Italy, and will continue so until she reduces her overgrown army and ceases to build colossal ironclads, every one of which, says M. de Laveleye, involves the ruin of ten thousand of the population. So it is likely that the less costly undertaking will be the first to be completed—namely, the providing Naples with a pure and abundant water-supply, which will be one great step in the right direction.

After the hygienic controversy comes the therapeutic one. Hypodermoclysis, practised according to the recommendations of Pacini—that is, when, and only when, the patient is in the stage of collapse—has been rewarded with a large enough measure of success to ensure it against absolute professional ostracism; but the same cannot be said of the exhibition of æthiops mineralis (black sulphuret of mercury), whether used as a prophylactic or as an active remedy, a question on which an animated correspondence is now being maintained in the leading Roman journals, professional and lay. Dr. Regnoli, an eminent physician of the Eternal City, has published a treatise on the æthiops mineralis, in which he reinforces the favourable testimony of Dr. Hayem of Paris by his own experience, having found it efficacious in 95 per cent. of the 241 cases in which he employed it. Its action, he maintains, is antiseptic on the comma bacilli; and to the objection that the black sulphuret of mercury is insoluble and therefore inert, Dr. Murino asserts that its solubility has been proved in his own practice and in that of Dr. Colapietro, the sulph-hydric acid being liberated in the system and impregnating with its characteristic odour the perspiration of the patients, while the æthiops has tinged the linen black. On the other hand, it is argued that Dr. Hayem obtained no successful results with the black sulphuret in confirmed cholera, but only in the preliminary diarrhœa, while even in this latter case the efficacy of the drug may have been shared by the lemon-juice in which he exhibited it. If the antiseptic action of the drug on the cholerigenous microbe is due to the sulphur in its composition, how is it that the eminently soluble sulphate of potash has not the same effect? Again, the drug has been tried in case after case in Busca, where the cholera has been very severe, but with absolutely no result whatever, while in Naples the profession have so little belief in it that it has not been tried at all. Dr. Murino, who holds that we can make ourselves cholera-proof by small doses of black sulphuret, and who therefore enters a cholera lazaretto "with a light heart," promises to return to the charge. From the great medical school of Padua, again, we have an imposing statement of the virtues of laudanum in the early diarrhœa of cholera, Dr. Carlo Tunisi maintaining that his Neapolitan brethren have rather neglected the opportunities afforded them by the drug, which, if taken in time, arrests the disease before it reaches that algide stage in which the sole remedy yet found efficacious has been hypodermoclysis. In Naples, indeed, the only physician of note who has placed any reliance on it has been Professor Semmola, but his partial success has been mainly among the civil population, where the medical man is apt to be called in too late, while Dr. Tunisi, practising on soldiers in barracks and prisoners in gaols, where every stage of the malady is under prompt surveillance and where the primary diarrhœa is immediately met by the opiate, never yet had a case which, after the exhibition of laudanum, drifted into the condition of collapse. And so

Digitized by Google

Naples, Rome, and Padua are engaged in something like a "triangular duel" over the efficacy of rival modes of treatment which have long been partially reconciled, with a certain measure of success, in India, namely, the exhibition of calomel and opium in doses of two grains to one grain, or two grains to half a grain for an adult. The communication of Mr. Johnson Martin to THE LANCET of August 23rd might be studied in Italy with much advantage.

There are certain phenomena peculiar to this outbreak of cholera in Southern Europe which should form the theme of careful official inquiry. After the outburst of the malady in Toulon its direction was much less northwards than southwards. Again, both in Italy and France it visited great seaports most heavily, while in Italy this curious spectacle was witnessed—it selected alternate seaports for attack. For example, it overleaped the populous and not over-cleanly Genoa, and alighted heavily on the less populous and not more insanitary Spezia. Again, it overleaped the less populous and decidedly insanitary Leghorn, and exploded with fearful violence in the more populous, though not very much more insanitary, Naples. What was its principle of selection? How is it that Messina and Palermo, seaports so severely scourged by it in former visitations, escaped so cheaply on this occasion? And how is it that the great provincial capitals—Turin, Milan, Venice, Florence, and Rome herself, all of them the scenes of virulent outbreaks on previous occasions—have hardly had one case? Able and experienced investigators like Professors Tommasi Crudeli and Moleschott might make a study of these questions and teach us a great deal. Meanwhile, an eminent authority, writing to the *Opinione* from Genoa, contends that Spezia and Naples were both made candidates for an outbreak of cholera by the Italian Government, who established a permanent lazaretto in the immediate neighbourhood of both seaports.

Rome, Sept. 22nd.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Sept. 18th:—

Armson, Frank Greasley, Yoxall, Burton-on-Trent.
Barker, W. J. Townsend, Redland-road, Clifton.
Chamberlain, C. Basham d'Eyncourt, Univ. Coll. Hospital.
Jones, Isaiah Henry, Maida-vale.
Simpson, G. A. Garry, Maryland-road, Sutherland-gardens.

At the Preliminary Examination in Arts, held at the Hall of the Society on Sept. 11th, 12th, and 13th, the following candidates received certificates of proficiency in General Education:—

SECOND DIVISION (in alphabetical order).—Alfred Alexander, John Hampden Barker,* F. Wells Beville, Edward Walter Brunton, P. M. Robertson Bryant,* Aubrey Conway,* Basil Wiseman Conway,* Frank Gillett Cory, Sydney Robert Cross,* Horatio Nelson Crossley,* Ernest Buxton Cutting, John Halliwell,* William Hindle, William Robert Howard, A. Talman Hott, David Owen Jones, J. Howard Jones, Arthur Edwin Joscelyne, Percy J. Kingston, C. R. Maitland, Francis R. Septimus Milton,* Eustace Ayton Payne, John W. George Prince, Ernest James Reynolds, Reginald G. W. St. Cadd, Eleanor Sophia Warner,* Richard Millbourn West.

* Passed also in Elementary Mechanics.

The following candidate passed in Greek alone:—

Herbert William Telmer Crew.

The following passed in Elementary Mechanics alone:—

Charles Stanger Bowker, Charles Edwin Cornwall, Stuart A. Charles Dallas, John Edward F. Hosking, Richard J. O'Halloran, Robert E. Franklyn Pearse, Nigel Alan Allison Trenow, Leslie Herbert Walsh.

JACOB H. STEWART, M.D., of St. Paul, Minnesota, who, in 1879, was appointed by President Hayes, Surveyor-General of Minnesota, died recently at the age of fifty-six.

A NURSE of the Wonford House Asylum, Exeter, has been fined 1*l.* and costs for slapping the face of a patient and for giving her a second bath as a punishment.

A NEW street paving has been introduced in Berlin, and is said to be superior in many respects to wooden blocks. It consists of layers of bricks impregnated with asphalte.

IN spite of the protestations of the Turkish authorities that the plague has ceased at Bagdad, the Persian and the Russian Governments are taking strict precautions against the possible introduction of the disease into their territories by pilgrim migrations.

THE discussion of the disease termed "miryachit" has been conducted with so much warmth in Naples, that an editor of one of the Neapolitan medical journals is said to have sent a challenge to a *brother* editor to decide the dispute by mortal combat.

A CENTENARIAN.—A man named Griffith Williams has, it is stated, just died at Bangor, having attained the age of 105. He was in receipt of out-door relief from the Bangor Union, and on the official list last year his age was returned as 102.

THE OTOLOGICAL CONGRESS.—The third International Otological Congress was held at Bâle from the 1st to the 4th inst. About forty papers and demonstrations of much interest to aurists were presented and discussed, and the Congress, in the proceedings of which some eighty members took part, may be described as having been most successful. The next Congress is to be held at Brussels in 1888.

METROPOLITAN FREE HOSPITAL.—A working-class demonstration in aid of the funds of this institution was held on the 21st inst. at Hackney. Between 4000 and 5000 members of various friendly, temperance, and trade societies assembled, and after the procession had marched through several streets, a charity sermon was preached at St. Paul's Church, Ball's-pond. Collections were held after the sermon and during the march of the procession from the church, and it is hoped that the demonstration will result in a sensible addition to the funds of the institution.

UNIVERSITY OF SYDNEY.—At the July meeting of the Senate of the Sydney University, the following resolutions were agreed to:—"That the lecturers in Clinical Medicine and Clinical Surgery, when appointed, shall hold their appointments only so long as they shall hold a clinical appointment in their particular departments in a recognised hospital." "That it be remitted to the Faculty of Medicine to consider and report on the whole questions of the status of the degrees in medicine granted by the University, and the registration of students in medicine."

SANITARY INSTITUTION OF GREAT BRITAIN.—The autumn Congress will sit at Dublin the whole of next week, excepting Monday. The Exhibition of Sanitary Apparatus and Appliances in connexion with the Congress will be held in the Royal Dublin Society's Buildings, Ballsbridge, from September 30th to October 18th. Congress tickets will be issued entitling the holder to admission to all the meetings, addresses, conversazione, and the exhibition held in connexion with the Congress. The price of the Congress tickets is half-a-guinea each. A reception room will be opened at the Royal Dublin Society's Buildings, on Monday, September 29th, at 1 P.M., and on the following days at 9 A.M., for the issue of Congress tickets, which may also be obtained previous to the meeting, on application to the Secretary of the Institute, or to the Honorary Local Secretaries, 42, Dame-street, Dublin. The lectures to the Congress, the sectional meetings, and the general meetings will be held at Trinity College, Dublin. The opening address will be delivered by Sir Robert Rawlinson, C.B., on Tuesday, at 8 P.M.

Medical Appointments.

Intimations, for this column, must be sent DIRECT to the Office of THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BIRD, F. DOUGLAS, M.B., M.R.C.S., has been appointed Demonstrator of Anatomy to the Melbourne University.

BONSAR, THOMAS WALKER, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Bishopton District of the Sedgefield Union, vice Thompson.

BRAINE, G. M. P., M.R.C.S., L.R.C.P.Lond., has been appointed Second Assistant Medical Officer to the Worcester County and City Lunatic Asylum, vice J. H. Beaty, M.R.C.S., L.S.A.Lond.

BRODIE, WM. HAIG, M.B., C.M.Ed., has been reappointed Medical Officer and Public Vaccinator for the Seal and Tongham District of the Farnham Union.

DENNING, C. ERNEST, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Senior Assistant Medical Officer to the Salop and Montgomery County Asylum, Shrewsbury, vice W. H. Packer, M.D., resigned.

Digitized by Google

DIXSON, CRAIG, M.D., C.M.Ed., has been appointed Honorary Surgeon to the Sydney Hospital.

DOUTY, J. H., M.R.C.S., L.S.A.Lond., has been appointed Senior Assistant Medical Officer and Deputy Superintendent to the Worcester County and City Lunatic Asylum, vice R. Atkinson, F.R.C.S.Eng., resigned.

FLECK, WILLIAM, M.D., M.Ch.Q.U.I., has been appointed Medical Officer to the Workhouse of the Wycombe Union, vice W. G. Hayden, L.R.C.P.Lond. & M.R.C.S., resigned.

GOODWYN, H., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator to the Newton Abbot Union, and Certifying Factory Surgeon for the District of Bovey Tracey.

HALE, CHARLES H., L.R.C.P.Lond., M.R.C.S., has been appointed Junior Assistant Medical Officer to the Salop and Montgomery County Asylum, Shrewsbury, vice Denning, promoted.

HOUISON, JAMES, M.D., C.M.Ed., has been appointed Visiting Medical Officer to the Grafton Hospital, New South Wales.

KITE, EDWIN W. D., M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to the West Bromwich Hospital, vice R. K. Delaney, resigned.

MARTIN, JAMES P., M.R.C.S., has been appointed Junior Assistant Medical Officer to the Wilts County Asylum, Devizes.

ROBBES, CHARLES E., B.Sc.Lond., B.A.Camb., M.R.C.S., has been appointed House-Surgeon to the Gravesend Hospital, vice R. J. Bryden, M.R.C.S., resigned.

SHERATON, GEO. ROBERT, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Sedgefield District of the Sedgefield Union, vice Thompson.

SMART, DAVID, L.R.C.P.L., M.R.C.S., has been appointed Medical Officer to the Bermondsey Workhouse, vice Cuolahan, deceased.

STIRLING, CHARLES, M.B., C.M.Glas., has been appointed Medical Officer for the No. 2 District of St. Olave's Union, vice Cuolahan, deceased.

WILLIAMS, CHARLES, L.R.C.P., L.R.C.S., L.S.A.Lond., has been appointed Admiralty Surgeon and Agent at Fort Isaac, Cornwall, vice Fulford.

Births, Marriages, and Deaths.

BIRTHS.

ALDERTON.—On the 20th inst., at Barnoldswick, Yorkshire, the wife of H. C. Alderton, L.R.C.P.Lond., &c., of a son.

BEATTIE.—On the 14th inst., at Ardmore House, Dewsbury, the wife of Robert Beattie, M.D., of a daughter.

BOTT.—On the 24th inst., at Kennington-park-road, S.E., the wife of W. Gibson Bott, L.R.C.P. & M.R.C.S., of a son.

CARPENTER.—On the 20th inst., at Trevathian, Beckenham, the wife of E. Carpenter, M.R.C.S. &c., of a son.

COLEMAN.—On the 20th inst., at Hill View, Streatham-common, S.W., the wife of Charles A. Coleman, M.D., of a daughter.

O'MALLEY.—On the 15th inst., the wife of Fleet-Surgeon O'Malley, H.M. Dockyard, Portsmouth, of a daughter, stillborn.

PENNY.—On the 22nd inst., at 194, Downham-road, Islington, N., the wife of William Lowry Penny, M.B.Cantab., M.R.C.S.E., of a son.

ROBINSON.—On the 20th inst., at 12, Albion-street, Hull, the wife of Arthur H. Robinson, M.D., of a daughter.

MARRIAGES.

FENN—COOK.—On the 19th inst., at Holy Trinity Church, Tottenham, Edwin Fenn, M.R.C.S., of Camden-crescent, Dover, to Mary Catharine, third daughter of G. K. Cook, of Grove-terrace, Tottenham.

KENDLE—COWAN.—On the 18th inst., at St. Nicholas' Church, Sutton, F. Wellesley Kendle, M.R.C.S., eldest son of F. Kendle, Esq., of King's Lynn, to Alice Annie, youngest daughter of George I. Cowan, Esq., of Moray House, Sutton, Surrey.

THALLON—DICKER.—On the 18th inst., at St. Paul's Church, Camden-square, William Morrison Thallon, M.D., son of the late Robert Thallon, of Brooklyn, U.S., to Emily Constance, eldest daughter of John Dicker, of Camden-square, N.W.

DEATHS.

KIMPTON.—On the 14th inst., at Cambridge-terrace, Burnt Ash-lane, Lee, S.E., John William Kimpton, M.R.C.S., L.S.A.Lond., in his 76th year.

PALMER.—On the 12th inst., Charles Palmer, M.R.C.S.Eng., L.S.A.Lond., of 44, King-street, Great Yarmouth, aged 54. No cards.

PROBYN.—On the 8th inst., at Reyharan, Hants, of diabetes, John Sutherland Howell Probyn, M.R.C.S., L.S.A.Lond., L.F.P.S., aged 44.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

ONE OF NATURE'S LITTLE WORKS.

MR. F. A. PALEY, in an article entitled "Sea Sand-grass as a Land-winner," published in *Longman's Magazine* for October, gives an interesting explanation of the cause of the sea-dunes to be seen on various parts of the British coasts. On the sites of these hummocks grows a little plant known as marram grass (Psamma arenaria), the roots of which are very long and tough. By capillary attraction, moisture is conveyed along these roots to the surface of the area on which the plant grows, and thus serves to arrest loose sand blown by the wind. By this means the dune gradually increases in size, and is firmly compacted by the interlacing roots of the grass.

Mr. Albert W. Graham.—The practice varies in different places. Our correspondent should ascertain from one of his friends the local custom.

Mr. Berne (Huddersfield).—By the phrase "bronchitic asthma" we understand spasmodic attacks of dyspnœa occurring in the course of "chronic bronchitis." The phrase is convenient, not scientific.

"WHY TROPICAL MAN IS BLACK."

To the Editor of THE LANCET.

SIR,—In your kind notice of my paper on the above subject, you conclude with these words—"The reasoning by which pigment, like the breath in the fable, is made to play the part of hot and cold, does not seem to be perfectly free from objection."

In this condensed criticism pigment is spoken of in relation to heat only, and undoubtedly pigment *per se*, whether immediately behind, or immediately in front of, a nerve ending could only have the effect of increasing those vibrations which are induced by heat waves; but it must not be forgotten that the skin of a negro and the skin of a European both measure 98° in temperature, owing to the interposition of a layer of surface moisture which by evaporation renders latent the excessive heat waves, and that it is this layer of surface moisture which thus protects the nerve endings from the excessive action of these heat waves, just as the layer of pigment protects the nerve endings from the excessive action of the light waves; consequently, the pigment is not called on to play the contradictory part of "hot and cold."

I am, Sir, yours truly,

NATHL. ALCOCK,
Surgeon-Major A.M.D.

Sept. 24th, 1884.

Mr. Donald Macrae.—Probably the successful candidate did not put the prefix to his name, which may have misled the committee as to the qualifications of our correspondent. It is not clear that he has any satisfactory means of redress; but the question is a purely legal one.

R. O. M. is referred to a general notice at the head of this column.

Digitized by Google

CHEAP DINNERS.

Apropos of our remarks on this subject on the 6th inst., our attention has been called to a pamphlet by Mrs. De Vere Mathew, published by Simpkin and Marshall, which has already reached a fifth edition, and the cost of which is eightpence. A glance at the contents of the little work is sufficient to show that it is likely to be very useful in straitened households, as well as to those who are engaged in the benevolent work of providing cheap and nutritious meals for the poor.

Mechanic.—We would advise our correspondent to refrain from rushing into print on a subject upon which his information is evidently very incomplete.

"WHAT IS A MINIM?"

To the Editor of THE LANCET.

SIR,—The letter which you were good enough to print under the above heading in your issue of Sept. 6th has received notice in a quarter, certainly most appropriate, with which, however, I was not acquainted. The Editor of the *Chemist and Druggist* has obligingly sent me a copy of his issue of Sept. 15th, in which I am editorially whipped (in a way that does not hurt much, happily, albeit he misspells my name), and, I hope rightly, instructed. The question involves more than I was aware of, and, if you permit, I will pursue it somewhat further.

The substance of the additional information supplied by the Editor of the *Chemist and Druggist* is contained in the italicised portions of the following definite statements:—"The minim is the 1·480th, and the fluid drachm is the one-eighth, part of *a fluid ounce, which is the 1·160th of an imperial gallon.* The *fluid* ounce, at the temperature of 62° Fahr., with the barometer at thirty inches, *weighs 437·5 grains.* These figures are not theory, but are statute law. They were given in an Order of Council issued in accordance with the Weights and Measures Act, 1878." I will not stop to pick holes in this, though the statement as to temperature and pressure inclines me to think that the "Orders in Council" referred to must be an interesting source of information, but should be glad to know whether the assurance about "statute law" applies to *both* of the preceding sentences. In that case the "fluid ounce" is in both said to be, by law, *equivalent to the ounce avoirdupois*, while the earlier states it to be also equal to 480 minims (? by law) Without actual reference to the "Orders in Council" I may not dispute this statement, but I may be permitted to feel very much surprised. Certainly, it falls in with something I have "heard say"—viz, that the fluid ounce is the twentieth part of an imperial pint (and therefore the 160th part of the imperial gallon); but, *per contra*, it falls *out*, most decidedly, with all tradition. The "wine gallon" is our oldest, and was quite recently the most uniformly recognised, standard of fluid measure. Even were all other evidence wanting, I think it would be hard to set aside that which I adduced from Thomson's Conspectus as to the relation in former days between the minim and wine gallon. As it happens, however, I have been furnished by a private correspondent with an extract (which he was kind enough to copy and send to me in answer to my letter in THE LANCET of Sept. 6th) from Hooper's Medical Dictionary, too long to quote *in extenso*, and too closely reasoned to bear mutilation, but which ends with these words: "The subdivision of the wine pint has therefore been extended to the sixtieth part of the fluid drachm, which is termed *minim*; and glass measures, expressive of such subdivision, have been adopted by the College." From what precedes this sentence of the extract it appears that there was a time when the measurement of small quantities of liquids was effected without the needful precision, through want of a recognised subdivision, and here we see how this want came to be authoritatively, though not legally, satisfied; but it was by the subdivision of the recognised wine gallon, not of the imperial. If, therefore, the Editor of the *Chemist and Druggist* is right in his reading of the "Orders in Council"—we need say nothing of statute law at present—that the fluid ounce which makes 480 minims is the same as the fluid ounce of which twenty go to the *imperial* pint, and *not* (mark this) the fluid ounce of which sixteen go to the *wine* pint, then, I think, we have as pretty a piece of conflict of authority as one could wish to see as the issue of discussion.

I am, Sir, your obedient servant,

Collingwood, Hawkhurst, Sept. 22nd, 1884. J. HERSCHEL.

P.S.—Since the above was not only written, but despatched, I have seen your issue of the 20th inst., containing four replies to my query about the minim, to acknowledge which I hope you will allow me space for a few more lines. It is plain that the conflict of authority which I point out above is both real and capable of easy explanation. It appears that the change of standard—if I may so call it—by which the "fluid ounce" ceased to be the sixteenth part of the old *wine pint* and became the twentieth part of the more modern *imperial pint*, was the definite act of those responsible for the London Pharmacopœia of 1836. The history of this change would no doubt be interesting, but I am not in a position at present to pursue the inquiry. For the moment I must be content to express my thanks to the Editor of THE LANCET for admitting my inquiry and to the gentlemen who have assisted in tracing the apparent error to a satisfactory origin. That the matter was not altogether unworthy of examination may, I think, be inferred from the fact that no one was prepared to reply "right away" that the minim of Thomson's Conspectus, which *was*, indeed, the measure of 57·60ths of a grain of water, was abolished in 1836, and superseded by the minim of 54⅔ grains (nearly) to the drachm, which is now in current use, although Mr. Martindale does *in effect* say so much, and more.—J. H.

Sept. 24th, 1884.

PUNISHMENT OF CRIMINAL LUNATICS IN CHINA.

THE subjoined extract from the *Pekin Gazette* of June 19th, 1884, as translated in the *North China Daily News*, throws a painful light on the condition of legislation in the Chinese Empire:—"Ts'ên Yü-ying reports the execution by the 'slicing' process of a lunatic who murdered his grandmother with a vegetable knife in a paroxysm of madness. The maniac, who was an orphan, was in charge of his grandmother, and though entreated by her relations and neighbours to place him in official custody she was too fond of her grandson to consent. One night a paroxysm of mania came on, and the maniac rushed into his grandmother's room, flourishing a vegetable knife and dancing about. His grandmother tried to take the knife away from him; he then stabbed her repeatedly, and she fell to the ground. The neighbours came to her rescue on hearing her cries, and seized the lunatic; but the wounds he had already inflicted were so severe that after lingering a few days she died. The grandson was then tried upon the capital charge, when it was conclusively proved that the crime was committed during a fit of insanity. The penalty for parricide or matricide being death by the 'slicing' process, this sentence was inflicted summarily upon the lunatic under the authority of the standing Imperial Death Warrant."

DISCOVERY OF A ROMAN VILLA, BATH-ROOM, AND BATH, WITH OTHER ROMAN REMAINS, AT LINCOLN.

To the Editor of THE LANCET.

SIR,—Recently Mr. Roseby's ironstone miners, in the process of opening up a new mining shaft in the Greetwell Fields, about half a mile from Lincoln, came upon the remains of a Roman villa, two or three feet below the surface of the ground. From the nature of the diggings much unavoidable damage had been done to the remains; but this much can be made out from the present excavations: that between two walls, running a considerable distance north and south and fifteen yards apart, several apartments existed, as indicated by walls, tessalated pavements, and large tile pavements. From these apartments three or four steps led down to a bath-room. The bath-room seemed to have been the front and most advanced basement room of the villa, and looked southward. From east to west the room measured about fifteen feet, and from south to north ten feet. From the east end of the north wall of the room the bath extended seven feet southwards along the east wall. The bath was between three and four feet in breadth, and its sides rose from the floor about two feet. The floor of the bath-room was formed of a beautifully white tesselated pavement, the tesseræ being about an inch square. The tesseræ of the bath-room were made of a white china clay, and were set in concrete. Tesseræ resembling those of the floor were extended up the sides of the walls for several inches, to form a dado. I am told that a dado has not been hitherto found in any other Roman building in England. In this case it was probably placed round the room to protect the lower part of the walls from the bath water. Tesseræ were also extended up the outside of the bath; the inside of the bath was formed of the same material as the tesseræ, but was quite smooth. The floor of the room, the dado, and the bath must have produced a fine effect, and must have looked like Parian marble. The well-plastered walls of the room were painted a creamy white, and the bordering of the walls and other decorations were painted with the greatest neatness and precision in fine reds, yellows, greens, blues, and blacks. On one piece of plaster I noticed the picture of a swallow, nicely drawn and painted. Two or three feet north of the bath-room, but in a different apartment, is a very deep well seven feet in diameter, which is still in a comparatively good state of preservation. The water of this well no doubt was used in the bath-room, and from the bath-room a well-constructed drain-pipe carried off the waste water. The house must have been the property of a Roman gentleman of taste and opulence. The site was well chosen; but, in consequence of the villa being built on the brow of a hill, the lower rooms were on different planes. The ancient Romans evidently had remarkably good ideas of sanitation. This villa was built on a mass of three layers of different kinds of concrete, to the depth in some places of upwards of three feet; and the drainage of the whole premises seemed, as the workmen remarked, to have been perfect. I may mention that the miners, in clearing away the soil immediately outside the villa, came upon a skull and some human bones, among which I found a tibia presenting a united fracture. I venture to think there is hardly a pathological museum in the United Kingdom which can boast of anything like this specimen of ancient surgery—a united fractured bone of an old Roman who lived, and certainly limped, seventeen or eighteen centuries ago.

I am, Sir, yours truly,

Lincoln, Sept. 5th, 1884. WILLIAM O'NEILL, M.D., M.R.C.P.Lond.

J. G. L. (Carlisle).—Among the descriptions of epidemic visitations the *chefs d'œuvre*, in a literary point of view, are those of Thucydides, Boccaccio, De Foe, and Manzoni, the highest merit belonging to the first and the last of these authors. The "Italia Militaire" (Florence, 1869) of Signor Edmondo d'Amicis contains a vividly dramatic account of the cholera-panic in Sicily in 1867. The narrative of the plague in "John Inglesant" has indications of power, but it is painfully elaborate.

Mrs. K. M. E.—We regret we are unable to assist our correspondent.

Digitized by Google

ANOTHER EPIDEMIC.

THE alarming spread of magnetic girls, says *Gaillard's Medical Journal*, deserves the immediate attention of sanitary authorities. Since the first case appeared, in the person of Miss Hurst, four more Georgia girls have been attacked, and are now on their way north, breaking umbrellas and otherwise displaying the terrible symptoms of magnetism. The disease is evidently assuming an epidemic form in Georgia, and it will spread throughout the country unless strong measures are promptly taken.

Mr. S. F. Cater.—1. We quite see our correspondent's difficulty, which we think, however, he overrates. The certificate of a medical man is understood to express merely an opinion where from the nature of things he cannot speak with certainty. There is nothing to prevent our correspondent amplifying the printed form by the addition of explanatory sentences. Whether a company can be sued on an ordinary written certificate depends entirely upon the terms of the contract. If no mention is made in the agreement that a particular certificate must be presented on application for a claim, the company have no power to dictate their own terms in the matter.—2. Wilson's Handbook of Hygiene and Sanitary Science, 5th edition, 1883; Bailey-Denton's Handbook of House Sanitation, 1882.

Mr. E. Seton Pattison.—The handbill is beneath contempt.

PROFESSIONAL AMENITIES ON BOARD PASSENGER STEAMERS.

To the Editor of THE LANCET.

SIR,—A is a medical officer on a first-class passenger steamer; B is a surgeon returning on the same to Europe on furlough. B prescribes for a saloon passenger, and requests A to make up the medicine, representing that the patient was known to him (B) at one of his stations. A obliges B by dispensing the prescription. The case being protracted, A suggests to B that he should be called into consultation, which B declines. Subsequently B sees other saloon passengers, and demands of A to make up the medicines, which A refuses to do unless in consultation with B.

1. Was A in the right in making up the prescriptions of B all through the case No. 1, as he had in the first instance obliged B by dispensing on the understanding that the patient was a friend of B's, even though B declined a consultation?—2. Would A have been within his right to have refused to make up B's prescriptions, either from the first or after he (A) had requested a consultation with B?—3. Suppose two or three saloon-class returning, and each wished to prescribe for some friend also returning, would A be in his right to point-blank refuse to make up any of their medicines, and to state that he was not their dispenser, and that he would not dispense unless he was in consultation?—4. Is it not contrary to all medical etiquette for passenger surgeons to prescribe for fellow passengers when there is a ship's medical officer on board?

I am, Sir, yours truly,

Sept. 15th, 1884. ENQUIRENS.

*** It is not necessary to give too categorical an answer to our correspondent's questions. Clearly, though in exceptional and slight cases such demands as B made may be acceded to with grace, it is not fair to treat the responsible officer of the ship as if he were the mere dispensing assistant of medical passengers.—ED. L.

Dr. F. Gerger.—In Austria the practice of medicine is, we believe, restricted to graduates of Austrian universities. The practice of foreign medical men may, however, be permitted by the Government after special application.

Walter should put the question to his medical attendant.

MEDICAL OFFICERS OF HEALTH AND GENERAL PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—Will you be good enough to inform me whether it be a usual course to adopt, and in accordance with medical etiquette, for a medical officer of health to visit and examine a patient of another medical man, but in his sanitary district, when the case is reported to be one of infectious character by the sanitary inspector.

I am, Sir, yours truly,

Sept. 16th, 1884. BREAD TRAY.

*** It is impossible that any general rule as to this can be laid down. Whilst it is quite clear that, in virtue of his office, a medical officer of health has no legal right to visit any patient without his consent or the consent of his friends, and whilst it is not very often that an actual examination of a patient is necessary to the performance of the duties of the officer of health, it is at times of importance, in connexion with an inquiry he is making, that he should see one or more patients suffering from infectious disease. Such visits should, however, generally be made in harmony with the medical practitioner in attendance, and when this is done no difficulty need be experienced.—ED. L.

Medicus (Croydon).—Thanks.

Bob.—We know of no book that will serve our correspondent's purpose.

AN OBSCURE CASE.

THE following statement of an obscure case, given in the words of the patient, has been forwarded by a member of the profession, with a request for its insertion, and in the hope of obtaining an opinion upon it by some of our readers:—"I caught cold while bathing in the sea about three months ago, and completely lost my smell and taste. I continued to bathe occasionally for about a fortnight, when I became ill with what I believe was inflammation of the nerves and membranes of the head, eyes, and nose, and suffered intense pain. These nerves and membranes are naturally very delicate, and I suffer very much at times in my eyes and head. I have now been in my usual health for about two months, but have not recovered my smell and taste."

Enquirer.—1. Gowers' Diseases of the Spinal Cord, or Ross's Treatise on Diseases of the Nervous System.—2. As a matter of fact, such appointments are regarded somewhat with disfavour, but we are not prepared to say with what justice.

Mr. Gorham (Tunbridge).—We shall be happy to receive the paper.

MEDICAL ATTENDANCE ON THE FAMILIES OF MEDICAL MEN.

To the Editor of THE LANCET.

SIR,—On April 4th, 1884, Mrs. S——, a widow lady, and a complete stranger to me, called at my house and inquired for me. I saw her, and she said her daughter, who resided in London, wished to come home for her confinement, and asked me if I would attend her. I acceded to the request, and booked the engagement. A few weeks afterwards Mrs. S—— called to introduce her daughter, Mrs. F——. In due time the confinement took place, which I attended. A day or two subsequently the husband came, and introduced himself as a medical man. This was the first intimation I had received of the fact, no mention having been made either at the time of engagement or the subsequent visit of introduction, nor even during the confinement. The subsequent attendance was long and anxious; for the child ultimately died when about five weeks old. Mrs. S——, after my attendance, gave me to understand that I should be paid for my services, and asked me to be as lenient as I could. Accordingly I sent in my account to Mrs. S—— (not to the husband, Mr. F——); but a few days afterwards Mr. F—— wrote to me, saying that he considered it very unprofessional of me for charging a medical man for services rendered to his wife and child. Now, what I should much like to know is—1. Was I right, or wrong, in making a charge, considering the circumstances of the case, Mr. F—— being a total stranger and a non-resident?—2. If I had been expected to attend gratuitously ought I not to have been made aware that I was to attend a medical man's wife, instead of being told of the fact after my services had been rendered? I have been in practice for over ten years, and have frequently attended the families of medical men, and have never made any charge; but these were acquaintances, or else living in the same town, and I knew I was attending a fellow practitioner's wife or family.

I am, Sir, yours truly,

Sept 15th, 1884. M.D., &c.

*** Agreeing with our correspondent, we cannot admire the uncandid way in which he has been treated. A medical man has never more reason to be thankful that he is a medical man than when a patient in his own family gives him anxiety and he finds that he can command without fee the willing and kind help of medical neighbours or medical consultants. But there is reason in all rules, and a good rule is not to be unreasonably used. If the lady did not wish to be confined in London, and the amenities of the profession were to be substituted for the usual fee, the very least that ought to have been done was that the husband of the lady should have written beforehand, and in the first instance, to the gentleman on whose kindness and time a serious demand was to be made. This is so obvious that we will not further insist on it. We insert the letter that in future a gracious custom may be ungrudgingly, and not brought into discredit.—ED. L.

Microscope.—The foreign microscopes have hitherto been preferred on account of the better quality of their objectives. The disparity between English and foreign instruments is much less now than formerly.

ERRATUM.—In the communication from Italy, published last week, p. 524, first column, line 25 from the foot, "lettuce or an olive" should be *lettuce or endive*.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir Risdon Bennett, London; Dr. Purcell, London; Mr. Rea Edwards; Dr. O'Reilly, London; Dr. Drysdale, Liverpool; Prof. Wharton Jones, Ventnor; Dr. H. Cooke, Preston; Dr. Wiltshire, Gowes; Mr. Cater, Dufftown; Dr. Herschell, London; Dr. W. A. Duncan, London; Mr. D. Macrae, London; Dr. Jamieson, Shanghai; Dr. Hunterick, London; Dr. Taylor, London; Mr. Charles Hawkins, London; Mr. Gamgee, Birmingham; Dr. Geo. An Inaugural Address

DELIVERED IN

ST. THOMAS'S HOSPITAL,

At the Opening of the Medical Session 1884-85,

BY SIR J. RISDON BENNETT, M.D., LL.D.,
FELLOW OF THE ROYAL SOCIETY.

GENTLEMEN,—It was, I believe, a saying of Dr. Johnson that "to judge rightly of the present we must oppose it to the past." Certainly, to judge rightly either of St. Thomas's Hospital and its School, or of medical science of the present day, it would be needful to look back, I will not say to bygone centuries, but at all events to the beginning of the present century. And to one standing in the position of him who has the honour of addressing you on this occasion there are many temptations to take a retrospective view and indulge in past memories. Nor should I despair of making such a retrospect interesting to many, perhaps to most, of my auditors. The history of such an institution as this cannot be devoid of either interest or instruction, not merely to members of our profession, but to all thoughtful men, to all true lovers of their country and mankind. For what would be the character of such a history? Would it not be the history of a long series of benevolent efforts to succour the destitute, heal the sick, and alleviate the ills of mankind? Would it not be the history of men whose lives were devoted to doing good to their fellow-creatures—of men whose efforts had been spent in investigating the secrets of nature and making every advance in science available for the benefit of humanity? Would it not be the history of one of the grandest and most venerable of those institutions which are the direct outcome of our common Christianity and the glory of our land?

But I do not propose to offer you any attempt at such a historical sketch, whether for the purpose of congratulating you on the present position and prospects of your hospital and school, or at the risk of posing as a *laudator temporis acti*. I wish rather to be allowed to ask you, as I asked myself after my former pupil, your distinguished and respected Teacher and Dean, had requested me to give the address on the opening of the present session, what is it that those who are entering on the medical profession are about to undertake? What is comprised in the preparation needed for rightly fulfilling the duties that will devolve upon them? These, surely, are questions that every one entering our profession should put to himself. But how few do so or give to them due consideration. It is only when we have entered on the duties of our calling, and by experience are made aware of the magnitude, nobility, and responsibility of the office we have undertaken that in our thoughtful moments we become to any adequate degree sensible of the requirements which our profession demands. The subject is far too extended and serious to be adequately treated in a brief address. But some very general considerations on a few points admit of being submitted for future thought; and if these should help you in any measure more adequately to realise what it is that you who are entering on your profession have undertaken, I shall be satisfied.

The poet tells us that "the proper study of mankind is man." But man is in a special sense our study; man in his entirety, physical, intellectual, and moral; man not only as the highest type of the animal kingdom, a constituent part of the created universe, and therefore subject to its laws; but man also as an intellectual and moral agent, subject to other and higher laws of the Great Lawgiver, of Him whose will is the one and only source of all law, whether physical or moral. Like all other living beings, we are subject to those laws and conditions on which life depends, and as intelligent and moral beings, members of a society of fellow-beings, subject to laws whose maintenance is essential to social life, not to mention those higher laws by which we are linked to a higher and more enduring life. All of us, therefore, must become more or less practically acquainted with the conditions under which we live, whether as individuals or members of society, and must learn, more or less accurately, the consequences of infringing the various laws to which we are subjected. The degree in which such knowledge is essential will differ in different circumstances and callings in life, but absolute ignorance is incompatible with either individual or social life. We, whose office it is especially to study all that relates to the life and health of our fellow-men, have to study man not only as an organised being in all his relations to the external world, but also as endowed with reason and a mental constitution with which his physical nature is combined, by which his material organisation is constantly influenced, and by which he is capable of influencing and is influenced by his fellow-men.

It requires but a very slight acquaintance with the practice of our art to learn how greatly the equilibrium of health depends on the due regulation of psychical as well as physical causes, and how much the influence and success of the medical adviser depends on the exercise of those subtle powers which are not to be weighed by grains and ounces. In common with all men, we are bound to be just, manly, gentle, and loving towards all men with whom we have to do; but as members of a high and noble calling, to whom not only the lives and health, but to a large extent also the private and social interests, of our fellows are entrusted, we are under moral obligations of special and solemn stringency. We must learn not only how to regulate our own mental and moral powers so as to exercise our art with the fullest benefit to our patients, but must make it an important part of our study to watch, analyse, and estimate aright the various and ever-varying mental manifestations of our patients. It would be a great mistake to suppose that mental and moral philosophy, the study of the intellectual powers, were required for those only who intend to devote themselves to psychiatrics. Nor is it merely as contributing in no small measure to our therapeutic power that such studies are important. In the more strictly scientific departments of the investigation of disease—etiology, diagnosis, and prognosis—they are of equal moment. There is good reason for believing that in our present state of civilisation many more of our most important diseases than we have hitherto imagined have not merely a nervous, but a strictly mental origin. Happily, through the labours of such men as Bell and Marshall Hall among others, and by means of experimental physiology, our knowledge of the nervous system has been greatly advanced. The influence of mind over body is indeed no new discovery, though of late much more has been affirmed than can be proved of the influence of the material on the immaterial. Where the initiatory steps in the production of disease take place, and what is their precise nature, are indeed questions which physiologists and pathologists alike confess to be involved in mystery. But that in many instances their first manifestation is in the nervous system there is good reason for thinking, and that mental states and impressions do not only induce functional disturbance even to the extent of sudden arrest of function and consequent death we have abundant proof. The action of the heart, respiration, and secretion are all greatly influenced by mental states. Moral emotions that may cause the death of the mother by sudden arrest of the heart's action may also destroy the life of the infant at her breast by poisoning the nourishment that she supplies. The effects of remedies are largely determined by mental states. They become potent, modified, or inert, according to the mental state of the recipient, and this constitutes no small difficulty in determining their true action.

It is therefore not merely as a part of that general culture and preliminary education required of all who claim to be well educated that it behoves us to give mental philosophy or study of the intellectual powers a place in our curriculum. Nor is it merely as members of society and fellow-workers that we are bound to be guided by sound views of moral philosophy or ethics. For the direct purposes of our profession we need to give due regard to the reciprocal influences exerted between mind and body, to the moral powers with which we are endowed, and the modes in which they can be brought to bear on the welfare of our patients. The will, the imagination, emotions, affections, and desires, hope, fear, moral habits and conscience, all exercise an influence on the aspect, course, and final issue of disease. They require each in their turn due consideration from him who would rightly fulfil all that duty demands; or ensure his own success.

How often do we not see an ignorant empiric succeed in cases that have baffled the efforts of legitimate scientific

Digitized by Google

physicians, whilst we perhaps merely pity the credulity of the patient or sneer at the ignorant pretender to science? His so-called remedies have probably been absolutely inert, but he has called into action powers to which we have attached too little importance, or have altogether neglected—the stimulus of hope, the sedative of confidence, or the mere diversion of the attention from objects which, by their absorbing and depressing influence on the mind, have enfeebled and exhausted every vital power.

But if on the part of our patients and in the ordinary intercourse of life it is important to avoid the two extremes of credulity and scepticism, it is doubly so for us who are engaged in investigating the complicated phenomena of life and all that concerns its maintenance on the one hand, and on the other all that relates to the origin, nature, and prevention of disease. How vast is the field of our observation. How varied, intricate, and often mysterious are the subjects of our investigation. How numerous the fallacies and errors to which we are exposed. How difficult to elicit even the most fundamental truths that are to be the basis both of our science and our art. How important is it that we should be provided with all that constitutes a well-trained and regulated mind, in order to secure and make available for our great purpose in life truth and truth only.

Both our science and art are largely based on the observation and collection of facts. Now, there is a great difference in the observing powers possessed by different individuals; but we all require to carefully cultivate these powers, and by habits of close and continual practise render them both quick and accurate. Having ascertained, as carefully as may be, the certainty of our facts, the utmost care and honesty of purpose are required in tracing their mutual relations and drawing conclusions from them. All prejudice and preconceived notions must be excluded in determining whether any two facts stand in the relation of cause and effect, and in deducing general principles from any number of facts. Habits of close reasoning and the exercise of sound judgment are essential to our success. In medicine the difficulties are far greater than in the physical sciences in applying the strict rules of philosophy to the investigation and determination of truth. We have far greater difficulty in determining the uniformity of phenomena arising both from their greater variety and complexity, and also from our imperfect acquaintance with the influence of external agents on the living organism. We must still submit to be taunted with the uncertainty of medicine; but may, I believe, affirm with confidence that this uncertainty is daily decreasing, and may rest assured that it is only by the steady pursuit of knowledge along the strict lines of philosophical investigation that truth and certainty are to be attained. Let me here ask you to listen to what Lord Bacon says of the mental qualifications for the study of truth.

"For myself I found that I was fitted for nothing so well as for the study of truth; as having a mind nimble and versatile enough to catch the resemblance of things (which is the chief point), and, at the same time, steady enough to fix and distinguish their subtler differences; as being gifted by Nature with desire to seek, patience to doubt, fondness to meditate, slowness to assert, readiness to reconsider, carefulness to dispose and set in order, and as being a man that neither affects what is new, nor admires what is old, and that hates every kind of imposture."

Now, gentlemen, do not suppose that by such observations as these I am anxious to lead you into the barren fields of metaphysical speculation, and encourage you to form theoretical views of medical science, and become speculative practitioners. Far from it. I would rather warn you against wasting your time and muddling your brains by so-called systems of philosophy, which minister questions that are insoluble and are fertile only in raising doubts and spinning ingenious fancies and impossible theories. Such things may have a charm for some minds as affording intellectual recreation, and as possessing, indeed, a show of reason, but which for the real purposes of life are little better than verbal and vain janglings.

I wish simply to impress you, on the very threshold of your studies, with the importance of entering on them with that knowledge of your own intellectual powers and those principles of mental philosophy which are essential in all scientific pursuits. I wish you to keep in mind that in the practice of your art you have to do with the intellectual as well as the physical constitution of man, that you have moral relations to your patients of the highest importance both to their and your own welfare. If I might venture to recommend any particular books on these subjects, I would mention those of Abercrombie, particularly his admirable and instructive "Treatise on the Intellectual Powers."

When entering on the investigation of man's physical constitution as the highest type of organic life you will soon be made aware how intimately connected are anatomical or structural studies with those relating to function, both healthy or physiological, and perverted or pathological, and you will soon learn that whilst acquaintance with the principles of almost every department of physics and natural science is required rightly to understand the structure and actions of the human frame, we have at the bedside to do with something that cannot be studied in the dissecting-room and on the post-mortem table. The history of medicine sufficiently demonstrates indeed how little could be ascertained of vital actions or the nature of disease so long as the structure of the body and the physical alterations effected by diseased action were unknown. But with all the progress that has been made in recent times in our knowledge of our bodily organisation, and the flood of light thrown on the nature of those actions by which life is maintained through the advance in physical science, we are encountered at every step in our studies by evidence of the existence of powers and actions which all our physical science has hitherto proved inadequate to explain. Life is still the great mystery. And life, as we know it here, is ever passing into death. The very actions, so far as we know them, by which life is maintained are ever working by sure and inevitable steps to the destruction of life. All we can do is in some measure to modify those actions, and avert those causes that interfere with life, and so to prolong for a short space its continuance, and render it at the same time a more unalloyed source of enjoyment, a means of greater benefit to our fellow-men, and of fulfilling the great end of our existence. Day by day we are learning more and more how inadequate is our most intimate knowledge of structure to explain the real nature of those vital actions by which our frame is built up with materials obtained from without the body, and dead matter converted into living, and how small a portion of that pathological knowledge we so much need is derivable from the examination of morbid structures. But, happily, we have acquired much, and hope to obtain more, knowledge of the exciting causes of many diseases, and can in numerous cases arrest their action. We can understand much of the ways in which perverted nutrition and altered structure interfere with healthy function and endanger life. We can effectually remedy some of these things, and in important degrees diminish the perils arising from others. We can alleviate the pain and inconvenience associated with many diseases, and can save many lives from immediate and inevitable death. By our knowledge of the influence of external agents on living organisms we can diminish their danger to life and health, and make many otherwise impossible occupations compatible with human welfare. We can prolong the duration of human life, and have added to its sum total. We can comfort many an aching heart, solace many a weary mind, and bring joy and gladness into many a home in a way that no other body of men can. The benefits that we can confer, the good that we can do by our science and art are as extensive as humanity, and all ranks and conditions of men in ages yet to come will have cause to bless our Harveys, Hallers, Hunters, and Jenners.

But why do I venture to indulge in this strain of seeming self-laudation? Because I do not wish that you should be discouraged by the extent, variety, difficulties, and mysteries of the studies on which you are entering, but rather that you should congratulate yourselves on having adopted a course of life worthy to engage all the highest powers of man, and capable of conferring the greatest blessing on mankind. A life it is that will indeed not be free from care, anxiety, toil, and self-abnegation, but fraught with pleasures and satisfaction of the purest kind.

The connexion and relative importance of the different departments of your studies and the present aspect and position of our science you will learn from their respective teachers. The facilities and advantages which you possess in the present day for carrying on your study in the various subjects that lie at the foundation of all your professional education are very great; but with all these aids you must be prepared to find some of them at first irksome and devoid of much apparent interest. By industry and resolution you will soon get beyond those first steps that are always more

Digitized by Google

or less rough and difficult. As you advance your progress will be easier, and if you are at all worthy of your calling each step will be found of increasing interest and delight. On the actual position and prospects of our science in its various divisions I shall not attempt to enter. In some the outlook is more encouraging than in others. In some of the special subdivisions the practical application of our science has been followed by results of the most gratifying and salutary kind, whilst with respect to others sceptical outsiders are prone to exclaim "*Cui bono!*"

On one or two points I venture to offer a few remarks. Histological investigations have for some time been pursued with great ardour and diligence, and with undoubted and important increase of our knowledge both of function and structure, but whether with a corresponding augmentation of our therapeutic powers may be doubted, and whether such studies have not too much diverted our attention from the general laws of disease and the broad principles of practice is a grave question. At all events it is, I think, not a needless caution in the present day to warn you against coming under the description of Goldsmith's "puny pedant, who finds one undiscovered property in a polyp, or describes a hitherto unheeded process in the skeleton of a mole, and whose mind, like his microscope, perceives nature only in detail." I am speaking to those who are supposed to be preparing themselves for the practical duties of their profession rather than to scientific investigators. Again, many of the subjects of scientific inquiry in the present day are of such surpassing interest, and I may say fascination, as well as importance, that they are calculated to occupy the student's mind so as to interfere with other topics, and give a colour to his views both of science and art detrimental to his therapeutic success. Still more do we need to be on our guard against being influenced by the mere fashions and notions of the passing day, and taking up the endless whims and baseless theories that happen to have gained the ear and secured the patronage of the public.

It is certainly remarkable how little of our most trustworthy therapeutics has been the direct deduction from our scientific knowledge. Nay, how many of our most valuable and best-tested remedies have been acquired by accidental observation! How entirely ignorant are we of the mode of action of some of the most reliable! Quinine or bark from the time of its discovery has held its place as one of our most valuable and certain remedies, and we have recourse to it with the utmost confidence in intermittent fevers and neuralgias, knowing nothing of the real nature of its operation. The most philosophical physician, and one of the best of men, whom I have ever known, the late Professor Alison, at whose feet I had the privilege of sitting, and under whom I acted as clinical clerk, gave it as his opinion that we must look mainly for the advance of practical medicine to more accurate knowledge of the exciting causes of disease, and to the discovery of fresh specifics which may exercise the same influence over diseased actions as cinchona in intermittent fevers, citric acid in scurvy, and vaccination in small-pox. Two remedies that have come into use since his day, iodide and bromide of potash, approach nearest to the claim of being considered as specifics, and have proved of inestimable value; but their employment has not resulted from scientific induction either from physiology or pathology. It is also deserving of remark that in proportion as any medicine is found to be adapted to any particular morbid state, it is well borne by the economy, to the extent even of entirely masking or overcoming its ordinary physiological action. But experimental physiology and pathology have thrown much light on the action of many medicines, and we have thus gained no small amount of reliable information on the means at our disposal for modifying vital actions and controlling disease. The danger to life and the destructive course of disease are in many instances mainly referable to excess or defect of particular functional activities, which admit of being controlled by remedies proved to be capable of exercising the required influence. The incalculable blessings conferred by anæsthetics have been obtained by experimental investigations into their chemical constitution and influence on the nervous system. These and other instances of important augmentation of our therapeutic resources are a sufficient answer to the objections now so frequently and mischievously raised by mistaken opponents of experiments on the lower animals. Again, in the case of parasitic diseases, our knowledge of their true causes and nature has led to the discovery of appropriate and efficient remedies. And there can be no doubt that in other and more complex forms of disease, in proportion as we know their essential nature, our therapeutic powers will be increased.

Although there cannot, I think, be any doubt that by a judicious combination of medicines we often obtain advantages that could not be gained by single drugs, polypharmacy has been a great evil; but its days are well nigh gone, and the greater simplicity of our present practice is no doubt conducive to more accurate knowledge of the real therapeutic value of medicines. But whilst admitting the urgent need of still further careful observation and experiment in this field of inquiry, and though far from underrating the power of controlling, and even curing, disease already afforded us by many drugs, I would urge you ever to remember that therapeutics are no more comprised in the due administration of drugs than is pathology in a knowledge of morbid structures. It is well that young practitioners should see and appreciate the truth and depth of meaning in the dictum of Celsus, "*Optima medicina est non uti medicina*," a maxim which a certain class of practitioners have very dexterously turned to their own no small advantage.

Therapeia with the ancients comprised all that related to the care of the sick with a view to their comfort and relief; and in the present day hygienic rules, diet, and regimen are comprised under the head of therapeutics. It is here that we have met with most success and have won our greatest triumphs. It is here that all our labours in the investigation of structure and vital action have borne fruit; it is here that we have been able to profit by all the advances in physical sciences. Fuller knowledge of the exciting causes of disease has enabled us to make important steps towards their prevention; a more intimate acquaintance with the laws of morbid action and the natural history of disease has enabled us to foresee results and promote or obviate their occurrence. A closer acquaintance with nature's powers in maintaining health and repairing injuries has helped us materially in promoting her efforts and warding off all those influences that tend to interfere with or frustrate them. Surgery perhaps affords us the most signal and indubitable evidence of this; but some of the most complicated, and still in some respects inscrutable, forms of disease that fall under the care of the physician—specific fevers—might also be cited. More attention to the influence exerted on the aspect and course of disease by different circumstances and conditions of life, by differences of season and general epidemic character, has shown us the fallacy of supposing that the same disease is always to be treated in the same way, and thus leading us to prescribe for a name rather than for the particular case under view. If we take so common a disease as pneumonia, for example, of the nature, course, and general management of which we know more than of many other diseases, how different is its mode of access in different cases, the degree and kind of danger attending it; how different its progress; how different the constitutional condition of the patient, his hygienic and moral circumstances. Manifestly the plan of treatment and the action of remedies must correspondingly vary. Theoretical or scientific views of pathology and therapeutics must here give place to the sagacity, experience, and judgment of the physician, even at the risk of his reputation, by running counter to popular views and received rules. It is evident that when encountering new forms of disease, or which are new to us, we must be guided by analogy rather than by definite rules.

It may perhaps be questioned how far the varied aspects presented by disease at different periods will account for or justify the abandonment of remedies and plans of treatment that have been found successful in other times; or how far we are influenced consciously or unconsciously by theoretical views into which we have been led by recently discovered scientific facts. In practice we must still to a large extent be guided by those broad general principles that have been best established by observation, and stood the test of long experience. In our art, *vixerunt fortes ante nos;* and we have but to look to the records of the past to be convinced how large a part of our most trustworthy practical knowledge has been transmitted to us by men who have gained the admiration and gratitude of their posterity by their sagacity and powers of patient accurate observation rather than by the theoretical views and systems associated with their names. Systems of medicine have passed into limbo, and we are happily free, in the present day, from their shackles; but we cannot ignore or neglect knowledge accumulated in the past, because we cannot make it harmonise with

Digitized by Google

our more advanced physiology or the marvellous discoveries in the field of microbiology.

During your studies here you will have but little time for reading beyond what is comprised in text-books, and that little had better be devoted to general literature as a source of mental recreation from professional occupations. But the leisure hours of future life will be profitably employed in learning what has been thought and done by the great men of the past. In the history of medicine you will find much to interest as well as to instruct you. Stores of wisdom are to be found in the writings of bygone observers that may be made practically available at the present time, and assistance often obtained on questions of the day by learning the errors and mistakes, as well as the discoveries, of the past.

In practice each individual case of disease to which we are called must be made a special study. It is not enough to ascertain that we have to do with gout, pneumonia, or typhoid fever, whichever it may be; each example of disease and each patient must be made a special study. We have to take into consideration all that relates to the climate, season, hygiene, and social condition of the patient, his hereditary and constitutional characteristics, his idiosyncrasies and past history, so far as we can learn them. And in the management of each case there is scarcely any circumstance, however trivial apparently, that may not exert an influence on our success, any and every source of irritation, whether bodily or mental, the position of the patient or his bed, the aspect as well as the nature of his food, his prejudice in respect of a particular medicine, his liking or aversion for a particular attendant and all that relates to the nursing and economy of the sick room.

It is not enough to lay down rules of diet. You require to know that the food is properly prepared as well as its special adaptation to the patient's case; and to these ends you must know the principles of the science as well as the art of cookery. For cookery is a veritable science as well as an art. Among the poorer classes there is not only grievous waste from ignorance or neglect of the right methods of obtaining the full amount of nutriment from each variety of food, but many unfounded and hurtful prejudices against the use and best modes of preparing such food as is needed in sickness. You will render no mean service to your poorer patients by instructing them on such points, and will greatly enhance your therapeutic powers by a knowledge of the chemistry of food and the best means of preparing it for the purposes of nutrition. Your personal influence in the sick room will be more or less in proportion as you learn to exercise in each case the precise moral control that it requires; and whilst to secure the confidence, good opinion, and gratitude of your patients are in all cases legitimate objects, their real welfare and the fulfilment of your duty must ever override all considerations of your own social success. Assumed and affected manners are to be deprecated, whilst a kind and sympathetic manner should be sedulously cultivated. Gentleness should be combined with firmness, cheerfulness with sobriety, caution with confidence, and a general deportment consistent with the gravity of your office, and the particular requirements of the sick should be your habitual study.

In such a profession as ours every well-conducted and fairly qualified man may look with confidence to a certain amount of social success and opportunity of benefiting his fellows, may secure the esteem of the worthy and the blessing of such as were ready to perish. It is not indeed given to all to make discoveries in science, or effect important advances in our art; but each may do something, and it is imperative on all to make it an object, and consider it a duty, so to live that those who come after us may be the better for our labours. Some by the particular circumstances in which they are placed may have opportunity for special observation and investigation of particular [illegible] which should not be lost. All by careful [illegible] observation of nature and truthful records of work may contribute somewhat to the common stock of knowledge; but such records must be made, not with a view to a fleeting reputation or the gratification of personal vanity or ambition, but with the object of eliciting truth that shall prove to be for the good of man's estate. Whatever the genius of some or their special advantages may enable them to effect, it is by that close observation of nature, which all may and are bound to cultivate, that most of us can [illegible] what should be the desire of everyone.

"Now this natural logick prevails not, artificial too often faileth," says that quaint old philosopher, moralist, and physician, Sir T. Browne; "where nature fills the sails the vessel goes smoothly on, and where judgment is the pilot the rate of insurance need not be high; where industry builds upon nature we may expect pyramids; where that foundation is wanting the structure must be low. They do most by books who could do much without them, and he that chiefly ows himself unto himself is the substantial man."

Introductory Lecture

DELIVERED AT

UNIVERSITY COLLEGE, LONDON,

On October 1st, 1884,

BY W. R. GOWERS, M.D., F.R.C.P.

GENTLEMEN,—My first and chief duty to-day is a simple one. It is to bid a hearty welcome, in the name of my colleagues and myself, to those of you who are here to commence or to resume your studies. Of your choice of a profession I may have something to say hereafter. Of your choice of a place of study I need say little. For more than half a century University College has shown other schools how medicine should be taught. Almost every important step in medical education has first been taken by her. Thanks to her example, she now has many rivals, but remains surpassed by none and equalled by few, whether the test of comparison be that of method or quality of result.

With this word of welcome, my chief duty being done, I would gladly end. But an unhappy custom lays its heavy hand upon me, and compels me to introduce you to your work by the first of the many lectures to which you will have to listen. In doing so, I do not propose to pass beyond the immediate occasion that brings us together. I have too much sympathy with the interests that are foremost in your minds to-day to be able to inflict upon you any scientific dissertation. So I shall limit what I have to say to the work that lies before you and the profession you have chosen, even though I risk the accusation, so freely levelled at introductory lecturers, of talking platitudes. I confess the charge lies lightly on my conscience. For, gentlemen, what is a "platitude"? A platitude, dictionaries tell us, is "something flat." Well, this world of ours seems a flat place to people who are up in a balloon; but to those who have to live and work upon it—to climb its shelving slopes—to thread its mazy labyrinths, and rest beneath their shade, the world has characteristics which the epithet of flatness fails to epitomise.

And so I will begin with the most common-place of questions, and ask why you are here, and will anticipate the most common-place of answers, that you are here "to study Medicine." Would, for your sakes, that the act were as simple as the words. Even in outline the process is somewhat formidable. I have said that this is the first of many lectures to which you will have to listen. I am almost afraid to tell you how many they are, lest the prospect should be too much for your resolution. It is certainly, however, within the mark to compute the number of lectures and class meetings that you will have to attend, at not less than two thousand. It is not our fault, gentlemen. It is ordained and prescribed by the powers that be that you shall learn all things by oral instruction. Many subjects could not be taught otherwise. As regards others, I for one think that more laxity might be shown, and that the method by which knowledge is acquired might be left, in larger degree, to the choice of the student.

Nor is the prospect less formidable if the nature of your work is looked at. Those of you who aim at the higher qualifications will have to learn something of about half the sciences into which human knowledge has been divided, and of many you have to acquire not an elementary, but a practical knowledge. Besides the sciences that you are expected to study, many others have applications to the subject of disease, its prevention, and its treatment, although those applications are not so direct or so extensive as to make their study compulsory. Indeed, the sciences that

Digitized by Google

have no such relation are few. Almost every branch of knowledge, whether it deals with earth, or air, or water, with the physical properties of matter, or with the phenomena of organic life, with the processes of thought, or the social economy of communities, touches at some points the varied problems that present themselves to the practitioner of medicine. Nor can it be otherwise. For what is the work to which you address yourselves to-day? What is this Medicine to which you propose to give such strength as you possess and such life as may be before you? Let us try for a moment to gain a wider view of it, and see how vast is its significance, how extensive are its relations. Your life work is to be the prevention, cure, or alleviation of the diseases of man. Whatever else man is, he is at least this—the highest and most complex phenomenon yet discovered, or likely to be discovered, in the material universe; that in which the interactions of force and matter attain the greatest elaboration known to us or, indeed, conceivable by us. The highest form of matter, the most delicate adjustment of force, are in a nerve-cell of the human brain. Of the slow, never-resting tide of creative development, sweeping on, through ages far behind us, ebbing and flowing, and yet with sure advance—moulding into new forms and higher phases the mysterious elements on and in which it works,—it is with the ultimate result, the highest product, that your work lies. Physically man is part of the material world, inseparable. The phenomena of life are continuous with those outside the living organism, depending for their existence on that continuity, acted on by, and reacting upon, all the strange waves of varied forces, which, in their blending interaction, weave what we call the outside world. But elevation entails instability. The exquisite capacities of organic bodies are obtained by a complex adjustment of forces, held in restraint, ever striving to gain some lower and more stable state, kept in check by delicate counterpoise, in equilibrium that is destroyed by the slightest change, is indeed in constant process of destruction and renewal. By altered constitution or action the human body responds to every external variation, to every change in temperature, mechanical force, chemical constitution of its surroundings, and doubtless also to every alteration in electrical and magnetic states. No cloud can form, no rain can fall, without its influence. Each motion of our rolling world, each wave of light that reaches us from the far-off sun, each wind that bears to us the warmth of tropic seas or cold of mountain snows, determines some change in us. An alteration in the soil on which we live may modify altogether the processes of life. Hence we may see how wide must be laid the foundation of at least a general acquaintance with the sciences that deal with the material world, before an intelligent superstructure of special knowledge can be reared. With increased exactness in the study of the human frame, that necessary foundation has to be made wider and deeper. We are only beginning to see the application to physiology and pathology of the physical sciences. The structure of the body abounds with mechanisms and its action with processes, both in health and in disease, that can only be comprehended by a knowledge of the sciences that deal with the precise relations of constant forces, with the action of energy in solids and liquids, with the laws of light and of sound, and with the changing forms of force. Mathematics have a future application to human physiology and pathology of which only one province, the functions of the eye, affords at present an adequate illustration. You cannot properly understand the higher forms of organic life without some knowledge of the lower, in which the problems are simpler, and can be more readily comprehended, even if they cannot be solved. Moreover, the very lowest forms of life have been lately found to have the closest connexion with our work. Nature is always surprising us by the union of extremes. The labours of pathologists have added to the realm of biology a new province where it was least expected, and we may say least welcome. When I was a student the Professor of Zoology, whose genial enthusiasm will never be forgotten as long as his pupils live, commenced his lectures on the animal kingdom with an account of the corpuscles of the blood, and I presume our esteemed Professor of Botany will soon have to save his subject from its threatened exclusion from the curriculum by devoting half his course to bacteria, unless—which perhaps is more probable—a new chair has to be founded of, let us say, bacterio-phyto-zoology. When you have gained a knowledge of the sciences on which medicine rests, unfortunately, indeed, at the same time, you have to enter on the more special studies to which most of your time will have to be devoted; the study of those combinations which are so far distinct as to constitute, currently at least, separate sciences, and which we call by names that properly have wider meanings—"anatomy," or the art of cutting up; "physiology," or the science of the nature of things; "pathology," or the doctrine of deep feeling; "medicine," or the art of healing; "surgery," or handiwork. Around these chief divisions of the knowledge you have to gain are others of subordinate position, although scarcely of subordinate importance. Some of this preliminary knowledge you have doubtless already acquired, but that which remains is sufficiently vast in extent, intricate in arrangement, and complex in nature, to make the 2000 lectures only too few, and the four years you devote to the work only too inadequate. The task before you can only be accomplished by strenuous labour, pursued with even tenour, allowing no alluring pleasure to divert you, or idleness to hinder.

The mode in which the various studies should be pursued, will be sufficiently explained to you by those whose task it is to teach them. I would only impress on you one general principle, that should be ever kept in conscious view. It is a trite observation, often repeated, familiar enough in abstract but never enough familiar in daily effort, that the object of study is twofold. You are here for education as well as for instruction. You are here to acquire the knowledge of fact and rule and theory that you are to apply hereafter in the daily work of your lives, but you are here also to obtain the mental training needful for that application, needful to enable you to use your knowledge under conditions that are ever new and ever changing, to distinguish fact from fancy when they present themselves in unfamiliar aspect and often in borrowed garb—to trace new facts, new laws, among the manifold combinations of phenomena that will be around you in every day's work. Happily in each department of science the mental training needed to pursue it may be gained in the acquisition of the facts already known. No separate education is needed. If you study well, both wisely and thoroughly, the subjects that form your course, you will be, at the end of the time, qualified not only in the diplomatous, but in the fullest, sense of the word to enter on independent work. But the extent to which you obtain this training rests largely on yourselves. It is at once an important, perhaps the most important, part of your work, and it is that in which your teachers can do least for you. They can put before you fact and reason, but they cannot, or can only in small degree, compel you to observe, to realise for yourselves the value of evidence, to distinguish fact from theory, and to be on guard against the fallacies that lurk on all sides. They can test your knowledge: they or others can "coach" you and "grind" you, but the process of the instillation of facts, represented by these somewhat inapt metaphors, may leave you wholly untrained for subsequent work. Your "coach" may carry you through the lofty portals of Lincoln's-inn and Pall-mall, or the lower archway at Blackfriars, and leave you altogether unfitted for independent progress. Your "grinder" may pass you through his mill with such success that you emerge a flabby mass of factitious atoms kept in the semblance of form by the sack of a diploma, but it is only by your own continuous effort that you can gain cohesion and the power of organic growth. And this effort must be made from the commencement of your studies. Each of the subjects that occupy your earlier years has its own method, and yields you a separate training. In each facts are ascertained and theories are verified in a different manner, and this you should endeavour to keep before you in your daily work. This subject has been often dwelt on, and once here with an ability that I cannot hope to rival. I would refer you to, and urge you to study carefully, an introductory lecture that you will find in the library, bearing the revered name of Parkes, and I will content myself with a few instances to show you what I mean. The training given by the study of anatomy is chiefly that of observation—at once the most fundamental, and I might say the most difficult of all the mental processes involved in medical work; difficult, partly because it seems so easy, and a first clear impression is allowed to deter from thorough investigation; partly from the well-known tendency to confuse observation and inference, and to lose sight of the sources of error that the latter introduces; partly because facts have an inconvenient habit of presenting themselves where they are not expected, and when the attention of the observer

Digitized by Google

is otherwise engaged, often in some manual occupation. This is a fertile source of error and omission. It cannot, from the nature of the case, be altogether avoided, but it may be to a large extent lessened by careful training, such as that which is supplied by the study of anatomy. This, if properly used, is of inestimable value. The facts are simple, in that they are of one class only. They are limited; it is possible to make an observation thorough and complete. But much of the value of anatomy as a training is lost because the student is content to separate too completely, often endeavours to separate, the two parts of his work, the process of dissection and the process of learning. During the processes of tracing and cleaning, largely mechanical, he allows his mind to be occupied with other subjects, and when the task is over, sits down to learn his part as from a picture or a model. But by keeping his attention constantly fixed on his work, by noting over and over again, and in a systematic manner, the relation of the parts he is tracing, he may not only almost know his dissection by the time he has completed it, but he may gain the power of seizing every fact as it presents itself, although his attention is at the time occupied by the work of his hands; a power of inestimable value, especially to the surgeon and pathologist. Microscopic anatomy takes the student to a fresh range of facts of greater complexity, and ascertained by a more complex method of instrumental, instead of simple, observation, and experiment by means of reagents plays a minor but important part in the processes of identification of structures, an introduction to the use of experiment in its simplest form. He should endeavour to analyse the steps by which each conclusion is reached, since by this training in simple methods he will be better able to trace the process, far more complex, by which inferences are drawn, and so detect the dangers of fallacious reasoning, in the more complex sciences that constitute his later studies. So in chemistry, in which experiment attains its highest development, and the training in exact reasoning which it affords to the student is of inestimable value. It is unfortunately unavoidable that most students should study these three subjects simultaneously, but it is a wise modification of the older order that study of inorganic chemistry should precede that of physiology.

So large has become the cargo of knowledge with which the course of medical study has become charged, that the question has been necessarily raised whether the overladen vessel cannot be lightened by throwing overboard at least one subject, and by common consent Botany has been selected as that which may with least loss be spared. The loss, it seems to me, would be greater than is commonly assumed. From the point of view of education, as opposed to mere instruction, the value of botany to the student is very great. No elementary subject in the whole curriculum is capable of supplying in equal degree the training in the methods of his ultimate work. Structural botany supplies an additional and most useful training in observation; the practice of describing plants, so admirably systematised as it is in the teaching here, is an excellent education in note-taking, afforded by no other subject in the earlier course; while the process of the identification of plants, involving as it does exact observation and comparison of characters and the estimation of evidence, is almost the same in method as that of the diagnosis of disease.

If the student has duly profited by these earlier studies, he is prepared to enter with advantage on the study of physiology, in which he is introduced to the chief methods of ascertaining and verifying facts that are employed in the ultimate subjects of medicine, pathology, and therapeutics. Although the methods are, in part, the same, the higher degree to which experiment can be applied renders the conclusions of physiology far more certain than those of medicine and pathology; although far be it from me to suggest that everything in physiology is free from doubt. The value of this study as a mental training was insisted on not long ago, with characteristic ability, by one of whom University College is justly proud—Professor Michael Foster of Cambridge—and his main conclusions must command universal assent. But the student can only utilise physiology properly after the training afforded by the earlier studies I have mentioned, and its proper place is between those and pathology.

When you come to the practical study of the subjects that are to constitute your later work, and especially to clinical medicine, surgery, and therapeutics, you will feel the value of your earlier studies if you have properly used the training they afford. Strive in all your work after exactness, thoroughness, and keenness in observation; endeavour to analyse the process by which each fact is reached, remembering that the processes are always more complex than they seem; look out for every opening by which fallacy can enter; strive by every method you can think of to gain the utmost certainty attainable, in whatever it be, whether the diagnosis of a disease or the action of a drug; or, at least, relentlessly expose, and candidly admit to yourselves, the degree of uncertainty. It would be a help to the student if at the beginning of his career, instead of sometimes at its close, he had to acquire some knowledge of formal logic, but the steps of reasoning can be effectively traced, and the value of conclusions duly estimated, almost as well without the aid of formal logic as with it, provided the student uses every opportunity of acquiring the art, and begins with the simpler instead of the more complex processes. It would also be a great assistance if the methods of reasoning adopted in each science could be explained and illustrated to him in a systematic and formal manner when he commences its study.

I have ventured thus to insist on the importance of deliberate and conscious effort on your part to obtain to the full the mental training that your studies afford, because I can do so here without any qualms of corporate conscience. Although you have, alas, no longer the privilege of listening to one, whom here I need not name, through whose unrivalled teaching his pupils learned the importance of exact reasoning by the most masterly example of method ever presented to students of medicine; still I believe that there is no other medical school in which so much is done to educate as well as to instruct, to train the student as well as to propel him through his examinations. And I have ventured to insist upon this subject, because if we look around us, and read much of the medical literature of the day, it is difficult to avoid the conclusion that there is, to put it mildly, room for improvement. To put it more exactly, there is no department of science in which there is so much imperfect observation, hasty generalisation, and fallacious reasoning as there is in medicine. I was going to say, "there is no department of intellectual work," but as that would include politics, which is supposed to be intellectual work, the statement might be open to question; so I will leave you one comforting comparison. But in medicine, almost every day, fancies are formulated as if they were facts, theories are elaborated on data absurdly inadequate, and almost every conceivable error in reasoning is gravely perpetrated, and what is more, these things are welcomed with acclamation, when in any other department of science they would be put by with a smile. This is no doubt due in part to the large number of workers in medicine. There is of course some admirable work, researches as brilliant, and reasoning as exact, as any department of intellectual work can show. I do not say that the bad is out of proportion to the good, but I am sure that the bad would be less if more could be done to utilise the mental training afforded by the course of study.

There is another and very different province in which self-training is desirable. When you come to the practical study of disease, strive to acquire the habit of entering into the feelings of the sick, and into their modes of thought, to such a degree as to ensure considerate tenderness in dealing with them. Never forget that a "patient" means one who suffers, and that you come in contact with the tenderest parts of human nature. Remember that in those in whom pain, disease, and death are stern and trying realities of the present or the nearer future, the mental tone is altogether changed; and do not judge the sick by the standard of the sound. "Invest suffering with the reverence that is due to its sad mystery. It has its roots deep down beneath the surface of our life, and reaches, in each one, the inner depths of calm or storm, in a region into which you cannot pass except by tender sympathy and thoughtful care."

It is true that to enter fully and deeply into suffering, with the sympathy that is not only intelligent but "with-suffering," is impossible. A doctor's work would then be simply beyond human endurance. To him, as to no other, the darkest side of human nature is ever open; in his ears the deep undertone of sadness rings through every chord and melody of human life, now in the wail of pure distress, now in the discord of passion, now rising into the sweet but still sad music of patient resignation and self-sacrificing

Digitized by Google

love. Well is it for the world that it is possible to understand without enduring, or the helpers would be few. As it is, our lives are often saddened by the suffering that we cannot but share. No statement more untrue was ever uttered than that familiarity with the sight of suffering destroys the capacity for sympathy in medical men. It is one of the many statements that are made by crotchet-mongers and others in the present day regarding the members of the medical profession, their feelings, actions, and motives, which could not be made in public if the character of the profession as a whole and the value of its work were duly appreciated.

It has always seemed to me that the value of that work to the community is underrated in public estimation, and that its character is inadequately recognised. I do not say that it is so in the individual relations of practitioners, but the frequent depreciation of our efforts, the misconception of motive, deliberate or unconscious, the bitter and unjustifiable attacks permitted upon individuals, even in journals otherwise respectable, could not be made, because they would not be tolerated, if the public knew what our work as a whole is. Of course, in a body of men so large as that of which our profession consists, there are and must be some who disgrace the colours with which they serve. For their exposure we may be grateful; and if humour hunters us, we may join in the smile that it excites. But the cases to which I allude, examples of which must occur to the minds of many of you, are very different from these.

Consider one or two aspects of our work. Take the service it renders directly to the community. Attempts might be made to estimate the money worth of the lives that are saved, but the data are too imperfect to show more than how large it is. In Great Britain and Ireland there are about 20,000 medical men in actual practice. Most of these have scores, some have hundreds, of patients under treatment every week. I do not think it is an over-estimation to assume that each practitioner in active work is instrumental in saving one life a week. If you consider the varied cases that come under his care, the acute diseases, accidents, the double perils of childbirth, the dangerous maladies avoided by timely treatment, I think that this assumption is below the truth. But halve this estimate; assume that he saves two lives a month, or twenty-five a year—and many practitioners demonstrably save this number in childbirth only. In the aggregate even this low estimate amounts to half a million of deaths prevented every year. Is not this a service to the community before which most others, and many far more highly honoured, pale? And to this must be added the cases of slighter disease and suffering prevented and relieved, many times exceeding in number the deaths prevented, even when every allowance is made for the cases in which, alas! the resources of our art are still powerless. Take again the progress of sanitary science, which is adding so much to the health and longevity of the nation. To whom is this due? Sanitary work has passed so largely into special hands, that few remember that the movement is all but entirely due to our profession. It is to medical science that all the knowledge of the causes of disease is due, which has shown the way for prevention. It is to the efforts of practitioners of medicine that we owe the stirring of public opinion, by which the progress of sanitation has been rendered possible, and which has produced outside the ranks of our profession noble workers—only too few,—who have aided our efforts and advanced our cause. And to-day, in town and country, over the face of England, in the gloom of crowded cities, and in the fairer cottage homes, where Nature spreads her beauty over man's neglect, it is the members of our profession who labour untiringly in the cause, against the obstructions of ignorance, prejudice, and almost criminal apathy—obstruction too often successful, until the warnings given receive some fearful emphasis, as by such an outbreak as that at Kidderminster, or the awful avalanche of Death that has fallen on the city—of all in Europe the fairest and most foul. And in this labour, which is a part of the ordinary work of medical men, their motive is pure benevolence. The inverse ratio of the prosperity of the doctor and the health of the people has passed into a proverb. If all the efforts that the members of our profession are at this moment making, with all the energy they possess, were to be crowned with success, immediate and complete, one-half of the practitioners of medicine must starve or find some other calling. Search where you will, in the wide scenes of the present or the narrowing vistas of the past, and you will not find another instance of such a body of men making it a main and constant object of their lives to deprive themselves of half their livelihood. But the fact, of course, excites no surprise, because every man who enters the profession, in so doing, puts self and self-interest aside so far as his work is concerned, and places the welfare of others before his own. To approach his work in any other spirit would be monstrous and intolerable, if it were not inconceivable. The vast majority of our fellow-workers subordinate not only their own interests, but their own feelings and their own lives, to the welfare of others in constant and uncompromising self-sacrifice. And this being a matter of course to us is taken by the public as so much a matter of course to them, that it is almost ignored in the public estimate of the profession. Medicine is ranked the lowest of those callings that are by courtesy termed learned, and the highest social dignity that is conferred on her most honoured members is the lowest that could be offered.

It has been objected that many of the lives we save are worthless to the nation, and lessen instead of augmenting the common-wealth. But when every allowance is made for these the residue of useful workers saved, of those whose existence is the nation's strength, is vast enough to startle the most indifferent if it could be assessed at the lowest estimate of its money worth. But the objection carries us to a wider survey of our work, at which I can only glance. If we look, not at the individual or the nation, but to the race in general, what are we to say as to the influence of the art of medicine? The question is but part of a subject of the highest interest, but also of profound obscurity—the part played by disease in the physical progress or degradation of man. Few questions in the whole range of science have an equal interest, perhaps no one is involved in greater difficulty. We can get glimpses of the outlines of the problem, hardly any of its solution. And yet it is a question towards which many lines of discovery converge, and its elucidation would be their grandest crown.

It is sometimes suggested that the influence of our art upon the race is to promote its physical deterioration. We save from death many sufferers from constitutional maladies, or from actual disease many who possess a morbid tendency, and by them that tendency is passed on to their offspring, and thus the area of liability is slowly widened instead of being lessened by the early death of those affected. It has even been urged repeatedly that the tendency of modern civilisation and of the medical art as part of it, by enabling the weaker to endure, is to cause an infraction of the great law of the survival of the fittest. The last assertion is an example of the inability of even brilliant thinkers to grasp a problem beyond their own familiar province. Fitness is here a purely relative and not an absolute term. If the conditions of life are so changed that the weaker may survive, the change in the conditions at once transmutes unfitness that would be fatal to a fitness that secures survival. The great doctrine of the survival of the fittest seems to me less a law that has to be proved than an axiom, as self-evident as that two straight lines cannot enclose a space. And it must be remembered that whatever be the influence of medicine in favouring the hereditary extension of morbid tendencies, it is simply an instrument of the moral force, which, in range and in effectiveness, progresses with the advance of humanity, the force that finds its expression in benevolence and philanthropy. Absent from savage life, these have now become recognisable and increasing factors in the influences that are moulding the future of the race, and they appear likely to gain in force in ever-increasing ratio. But I think it is open to question whether the gloomy forebodings to which I have referred are justified. It is easy to gather facts in support of the opinion; but it is very easy to look only at one side of the question. Our knowledge of the influence of heredity in the causation of disease is constantly increasing, and we are apt to hastily assume that the influence itself is increasing; but of this there is no proof. The strict evidence is equally consistent with the assumption that the influence of heredity is unchanged, or even lessening. For, be it remembered, the facts on one side of the question are obtrusive; on the other they are inconspicuous, however numerous. Even in families with strong hereditary predispositions, it is the common rule for many more to escape than to suffer, and this in every generation. There is a constant tendency for the race to clear itself of disease, just as a polluted river purifies itself while it flows. Were it not for this, man, or at least civilised man, would long ago have disappeared

Digitized by Google

from the earth. And is it too much to hope that the growth of social wisdom, and the progress of medical science, may succeed in augmenting this influence to a far greater and more effective power than it is at present?

In another province—that of zymotic disease—the promise of the future is still more distinct. One of the elements of their origin seems almost within our grasp, and few can doubt that the investigations that are even now in progress and the discoveries already made, which have added a fresh lustre to medical science, discount them as you will, must soon be followed by practical results of the first importance. But we must not forget that the nature of the specific material in which these diseases apparently consist is but one element in the phenomena. On the other, the strange fact of specific liability, no light has yet been thrown; and yet, in its relations to individual, race, and species, it is at present far more strange, and may ultimately be found even more important, than the other. The familiar facts of the protection afforded by an attack of disease, a protection which bears no relation to severity, the virulence of disease in races which constitute a virgin soil, and the strange manner in which new diseases arise and develop into prevalence, suggest problems of the present and questions of the future to which no answer or solution can be offered, but they need not lessen the hope that is raised by the discoveries that are now in progress.

Such are your studies in the nearer future; such your labours in the years the distance hides; and what is your reward? Small enough, as recompense is weighed in the common balance. A living; that is something. Bread—and cheese, perhaps—for each who wisely selects and patiently pursues his course of work; placing duty before pleasure, fitness before inclination, permitting no errant impulses, no distaste for steady labour, to determine his career, or any fancy-fledged ambition to tempt him to a flight beyond his powers, a flight in which he cannot hope to soar, but must from inherent weight and by all-potent gravitation, quickly fall. For every steady worker there is perhaps a more sure prospect of what is called "earning a living" than any other profession or occupation presents, with less risk of a disastrous failure from causes outside his own control. Moreover, you have other rewards if you do not wilfully close your eyes to them. Much of your daily work may be drudgery; some may be repulsive; but the subjects that engage your energies are of transcendent interest. The world is not to you as it is to most other men. To you the book of Nature lies open. The knowledge you have gained has, or should have, given to you a new interest in the world of living creatures of all kinds—ay, and in what we call dead matter too. Human life, in its development and decay, and the ever-varied phenomena of disease, present problems of the highest interest and of never-failing succession. For you, as well as for the great student of Life to whom they were addressed, the poet's lines are true, if you will make them so:—

> "Nature, the old nurse, took
> The child upon her knee,
> Saying, 'Here is a story-book
> Thy Father has written for thee.'
> And whenever the way seemed long,
> Or his heart began to fail,
> She would sing a more wonderful song,
> Or tell a more marvellous tale."

But greater still as a reward for your labour should be the consciousness of the character of the work you are doing. To relieve suffering, to cure disease, and, above all, to preserve health—these are the objects of your life. It is to achieve these that your energies are taxed, your drudgery bestowed, your days and your nights devoted. Each hour's work sees, or should see, these ends in some measure achieved. Failures must come, and, baffled in many a struggle, you may at times despond; but remember that the good you do is always far more than you can see. Our failures are obtrusive; our greatest triumphs often imperceptible. "Nature effected a cure" we or others say, and say correctly, but it is certain that Nature would often effect a death were it not for the guiding influence of medical treatment; an influence that we often cannot trace in the unit, but which comes out clearly enough in the aggregate. In the region of preventive medicine the results, however vast, are, taken separately, quite invisible. We can no more trace the influence that keeps a man in health, who would have otherwise have died of fever, than we can trace the breeze that wafts a cloud across the summer sky. Hundreds of persons every day are saved from disease without the fact being known to them, or to those who save them. Is it no reward to have the consciousness that life and ease and health follow your daily path? I know that cavillers may object that motives relatively low may compel your work; that the maintenance of your own existence may be an object in prolonging that of others. But this does not influence the intrinsic character of your actions. The choice of a sphere of work you make or ratify to-day will leaven your future life, and the knowledge that the world is bettered for each hour's labour may be, and should be, to you a constant and enduring satisfaction.

There may be—nay, there must be—many here to-day to whom words of farewell are more appropriate than those of welcome with which I commenced. Your student life is almost over; the graver work for which you have been training is close at hand, and soon in town or country, upon sea or shore, you will have entered on it. Wherever your lot may be cast—it may be near, it may be far away, under strange stars, in unfamiliar scenes—your College looks to you, and will not look in vain, to keep her name unsullied, to make your plane of study a passport among members of your calling, a guarantee of honour and trustworthiness. She looks to you, and will not look in vain, to carry on the high traditions of her past—to keep the torch she hands you brightly burning, to lighten the dark places of human life. She looks to you, and will not look in vain, to take your part, humble or high, in the great contest with disease and death, in the great work of gathering the knowledge that is power, and the wisdom that is life. Vast is the field of labour: no hand unwelcome, no effort to be spared. Fierce is the contest, unremitting; ever spring afresh the hydra-heads, and for no moment can the sword be sheathed. But it is not for ever; not, at least, in present inequality. Who that reads, with thoughtful eye, the signs of this century's advance, can doubt the issue? Though still the storm-clouds gather and the sky is dark, yet far away, and slowly coming nearer, there is light. Not we nor our successors for many generations yet to come may see it, save in glimpses few and faint. But come it will, and you may aid its advent. You may lessen the present gloom, and you may hasten the dawn, which, now flushing only here and there a mountain peak, shall surely broaden into perfect day.

ON PREPUCE GRAFTING.

By R. CLEMENT LUCAS, B.S.Lond., F.R.C.S.,
SENIOR ASSISTANT-SURGEON TO GUY'S HOSPITAL, AND TEACHER OF OPERATIVE AND PRACTICAL SURGERY IN THE MEDICAL SCHOOL;
SURGEON TO THE EVELINA HOSPITAL FOR CHILDREN.

AMONG the disadvantages which may be urged against the practice of skin grafting taught us by Reverdin are the pain and scarring the patient must suffer to provide himself with the cuticular fragments required to close his granulating wound. Whilst working men yield up their arms without murmur to supply cuticle for other parts, with women the difficulty of obtaining skin increases, and with children it becomes a cruel torture which no surgeon would willingly subject his patients to if he could obtain good results by other means. It is, therefore, at children's hospitals that the difficulty of obtaining skin to cover the enormous granulating surfaces often left after burns is especially felt; and my object in this paper is to point out that at these institutions there is a plentiful supply of skin removed which may be usefully turned to account. The number of children that are brought to these hospitals for phimosis is so great that many days will never elapse without the surgeon being called upon to perform circumcision. In recommending that the skin of other patients be used to assist in the closure of wounds, I cannot too strongly urge that the surgeon should use every precaution, never to lay himself open to the charge of having thereby communicated disease. But in the prepuces of children there is seldom any danger. When, however, balanitis is associated with phimosis I always make it a practice (for the sake of the child to be circumcised) to cure the balanitis before removing the foreskin. The surplus skin of this part, from its suppleness, thinness, and vascularity, appears to be peculiarly adapted for transplantation, so that I have found grafts from this source adhere when those from other parts

Digitized by Google

have failed. And again, wounds whose granulations appeared coarse and ill adapted for grafting have accepted prepuce grafts when I little anticipated a favourable result. About three years ago a case of acute cellulitis of the lower extremity, which came under my care, resulted in extensive loss of skin both in the thigh and leg. In this case, when the granulations had assumed a healthy appearance, grafts from various sources were placed upon the wound, and I was then favourably impressed with the superiority of the prepuce skin. The coarse skin with dry cuticle upon it, which may be obtained from amputated fingers, is far less satisfactory, adhering with less certainty and growing with less rapidity. The time which may be allowed to elapse between the removal of the skin and its application in the form of small grafts to a wound I have not accurately determined, but it is probable it may be extended till signs of putrefaction begin to appear. I have not hurried to place these pieces of skin on the wound, and from half an hour to an hour may sometimes have passed before they were made use of. In no case have I placed them in hot water or made any provision for maintaining them at the temperature of the body. If the recipient for the grafts lived at a distance from the person yielding the skin, I believe the skin might be conveyed in a small glass bottle or wrapped in gutta-percha without loss of vitality for some hours. The following case, which has recently been under my care in the Evelina Hospital, will illustrate the value of prepuce grafting in children. It was reported by Mr. Milligan, the registrar to the hospital.

"M. B——, aged two years and a half, was admitted into the Evelina Hospital for Children on November 23rd, 1883. The child had been severely burned on the abdomen twelve days previous to admission. It was taken after the accident to a medical man, who applied some dressings to the wounds, but from that time till the child was admitted the dressings had been left untouched. When taken in it was in a most foul and stinking condition, as might be imagined after dressings had been left twelve days. In parts the granulations had literally grown into the dressings, and were torn in removing the lint. The size of the granulating surface was six inches in transverse measurement, and four and a half in vertical diameter. After the wound had been cleaned it was dressed with carron oil. The child was ordered milk, beef-tea, and an ounce of port wine in twenty-four hours. On November 26th, as it was sleeping and eating well, it was put on fish diet. On December 17th it was noted that the wound, though decreasing in size, was healing very slowly, the granulations being much too vascular and large, bleeding freely at every dressing. Caustic was applied from time to time. On December 30th the report remarks that the healing was progressing slowly. On January 16th, 1884, there was still an ulcer three and a half inches in transverse diameter and an inch and a half or more in vertical measurement, the edges of which were much raised, and the granulations vascular and unhealthy. Mr. Lucas took the prepuce of an out-patient, whom he had circumcised about half an hour previously, and cut from it about twenty-eight grafts, which he applied so as to form bridges across the wound. These bridges were protected by strips of green oil-silk, secured by strapping. Lead lotion was applied on lint over the wound and gutta-percha tissue externally. The grafts were protected for five days. On Jan. 23rd it was evident that nearly all the grafts were growing. The wound was divided up by bridges, from which cuticle was rapidly extending. On Feb. 1st the wound was very much diminished in size. On Feb. 14th the child was discharged cured."

It is possible that some surgeons may take a sentimental objection to this method of healing large granulating sores; but any such feeling should yield to the excellent practical results which may be obtained by it. The only reasonable argument against it is that disease might by careless grafting be introduced into the system of a healthy child; but this is so remote that with ordinary caution it would be impossible. On the other hand, I believe the prepuce of a child posseses a germinal vitality, which renders it peculiarly serviceable for grafting.

Finsbury square, E.C.

PUBLIC PARKS AND OPEN SPACES.—On the 28th ult., the two verdant spaces enclosed within Canonbury-square, Islington, were thrown open to the public.—A new public park, situated in the central part of Huddersfield, was formally opened by the Mayor on the 27th ult.

CASE OF GLIOMA OF THE PONS VAROLII.

By H. FRENCH BANHAM, M.A., M.D. CANTAB,
PHYSICIAN TO THE SHEFFIELD GENERAL INFIRMARY.

THE subject of this case, a boy aged twelve, was admitted into the Sheffield Infirmary on Oct. 30th, 1883, and the following notes were taken at the time. Until quite lately he has been an intelligent lad and successful at school. He had measles five years ago, since which time he has been somewhat deaf, had a discharge from both ears, and been in delicate health. The discharge from the ears ceased a year ago. Slight alteration of his speech was noticed three months since, when also he began to complain of headache. Six weeks afterwards some squinting was first observed, the left being the affected eye; and he began also to be troubled with giddiness, from which indeed in walking he occasionally fell. He has not had any cramps or convulsions, or fits of any kind. He is not known to have had any injury to his head. His father died at the age of thirty-six from phthisis.

Condition on admission.—He is deaf with both ears, more especially with the left; quite conscious, but so emotional that he seems disposed to cry when any question is put to him. His utterance is drawling and indistinct. There is paresis of the right arm and leg, the movements of these members being limited, slow, and interrupted. The deep reflexes in both legs are exaggerated, but there is no ankle clonus. The superficial plantar reflexes are almost absent, especially on the right side. There is facial paralysis of the left side, and the orbicularis palpebrarum is so far affected that the eye can be only half closed, and there is congestion of the outer part of the left conjunctiva. There is extreme left internal strabismus, the right eye cannot be everted beyond the middle line, but there is no evidence of paralysis of the right internal rectus, as has been sometimes noticed in cases of paralysis of the internal rectus of the other eye. The pupils are equal and act to light. There is nystagmus of both eyes. The ophthalmoscopic examination gives evidence of commencing optic neuritis. The tongue on protrusion deviates to the right. Taste (tested with alum, sugar, tartaric acid) is rather defective. Respiration is somewhat sighing. There is no "tache cérébrale." The muscles of the paralysed parts, including those of the face, give a normal electrical response. The lungs and abdominal organs appear to be healthy. There is no pyrexia.

Nov. 8th: Since the patient came under observation, the chief changes that have taken place are: (1) his intelligence is somewhat clouded; (2) the deafness has so increased that it is now difficult to make him hear; (3) the paralysis of the arm and leg is more pronounced; and (4) he has emaciated somewhat.

The first thought that naturally suggests itself in connexion with this case is that there is a chronic abscess of the brain associated with some disease of the internal ear. I am, disposed, however, to think, from what I can learn from the boy's mother, that until lately the deafness has been somewhat slight, and might be accounted for by some catarrh of the external meatus. The pronounced deafness which at present exists is, I believe, of central origin. It is scarcely possible now to prove this by any of the ordinary tests. I am inclined to favour the hypothesis that we have here to do with a cerebral tumour, and that it is a tubercular mass or a glioma seems not unlikely. Its locality is probably in the left half of the pons Varolii on a level with the nucleus of origin of the sixth and seventh nerves. It is possibly more extensive than this, implicating, it may be, the cerebellar peduncles, or perhaps the upper part of the medulla oblongata, and involving the restiform bodies. In the position of the pons Varolii that I have indicated, the resulting paralysis would be due to the compression of the pyramidal tracts previous to their decussation, while the facial paralysis and that of the external rectus would be upon the side of the lesion. The diagnosis of tumours of the brain is beset with difficulties arising from our imperfect knowledge even now of the functions of the different parts of the brain, from the fact that tumours and abscesses occasion not only local effects by pressure and displacement, but also by the congestion, hæmorrhage, and softening which sometimes take place in adjacent structures, and also owing to effects produced in remoter parts of the brain by transmitted excita-

Digitized by Google

tion, emboli, &c. Still another source of confusion is the co-existence in some cases of several tumours in different situations.

The above notes were brought before the Sheffield Medical Society in November last. The patient's condition from the date of his first introduction to the infirmary continued (as it has done apparently from the commencement of his illness) to become progressively worse; the paralysis deepened, the deafness became absolute, and for several weeks he lay restless and almost motionless, so that it was difficult to say at any time how far consciousness was intact. Death took place January 23rd, and the following day a post-mortem examination was made.

Morbid appearances.—The only part of the brain that presented any morbid appearance was the pons Varolii. This externally was of almost more than ordinary whiteness, was enlarged to fully twice its normal size (the left lobe being much larger than the right), and the consistence of the whole was greatly increased. The transverse fibres stood out with unnatural distinctness. In the left lobe and extending inwards to near the median raphe was a semi-translucent mass about the size of a hazel nut, and presenting to the touch the feeling of firm jelly. It was of a reddish-grey colour, and merged by insensible gradations into the surrounding tissue. In the right lobe of the pons was seen a somewhat similar mass, but smaller, and of a light-grey colour. This was probably a more recent formation.

Our house-surgeon, Mr. C. Atkin, has prepared some admirable microscopical sections of the tumour, which show its minute structure to be such as was expected from its naked-eye characters. The tumour seemed to merge so gradually into the surrounding healthy tissue that it was difficult to mark out its exact limitations.

Sheffield.

THE TREATMENT OF RUPTURED KIDNEY.

By H. A. REEVES, F.R.C.S. Ed.,

SENIOR ASSISTANT-SURGEON AND TEACHER OF PRACTICAL SURGERY AT THE LONDON HOSPITAL, ETC.

THE following very interesting case presents in its history and post-mortem results a very good text on which to base my views as to the management of similar cases. The comments form part of a clinical lecture recently delivered at the London Hospital.

T. W——, aged nineteen, fell from a cart, and was admitted into the London Hospital on the same day (May 13th). His seventh and eighth right ribs were fractured near the costal cartilages, and there was localised surgical emphysema. He complained of pain on the right side of the abdomen and loin, but there was no external evidence of injury. The same evening his urine contained a little blood, but only just enough to make it smoky. Between the 13th and 22nd the pain in the abdomen and flank diminished, and abdominal discomfort was only complained of occasionally, while the hæmaturia remained the same as on admission. On the morning of the 23rd he became suddenly faint, and passed a pint and a quarter of nearly pure blood, and during the next four days he passed a large quantity during each twenty-four hours. His pulse was rapid and feeble, temperature high, and surface pallid. He complained of pain over his bladder, in which region there were dulness and tenderness, so a catheter was passed, and a good deal of bloody urine and some small clots withdrawn. There was considerable vesical tenesmus, and the lad seemed to ease himself by pressing on the end of the penis. During the second week the urine became ammoniacal. On the 27th hæmaturia entirely ceased for twenty-four hours, when he had another attack which lasted until a terebinth mixture every two hours was prescribed, followed next day by subcutaneous injections of sclerotic acid. These stayed the external hæmorrhage for a few days, or perhaps it would be more correct to say appeared to stay it, for internal bleeding must have been going on, as was shown by the large quantity of blood and clots found post mortem. The abdominal and lumbar tenderness increased; the muscles on the right were very rigid. There was great pain over the region of the right kidney and over the hypogastrium, and in the former situation there was a distinct sloughy fulness. The tongue became dryish and brown at centre, the pulse and temperature indicated inflammatory mischief, and his countenance became anxious. Dr. Langdon Down and Dr. Stephen Mackenzie saw the case, in consultation with me, on the Friday of the third week of his admission, and agreed that if the lad did not improve it would be justifiable to perform nephrectomy next day. On the Saturday he was no worse than on the previous day, though in a low condition. He was seen by a senior surgical colleague, in deference to whose opinion the intended operation was not done. During the remaining week of his life there was little or no hæmaturia, but the lumbar tenderness and pain increased, and the symptoms of peritonitis supervening, he died a month after admission.

Necropsy.—This was made by Dr. Charlewood Turner, and only the important points are here given:—Body exsanguine. Rigor mortis moderately well marked. No external sign of injury. The seventh and eighth ribs were the only ones fractured. No injury to the diaphragm could be made out, and there was no pleurisy. The abdomen contained a moderate quantity of blood-stained serum, and at its right posterior aspect was a fluctuating swelling of considerable size, on cutting into which a very large quantity of blood and broken-down clots was turned out. There was much difficulty at first in recognising the kidney, but on cleansing the parts its remains were made out, and it was found that only a small portion of its upper and lower ends was left, and this was much blanched. The remains of the kidney substance formed a broken-down pulp. It could not be clearly made out if the renal vessels were torn, but the pelvis and upper part of the ureter, though severed in part, still remained attached to the organ. There was a rounded venous-looking tumour in the neighbourhood of what was taken to be the hilum, and Dr. Turner kept this for dissection to ascertain if it were a traumatic aneurysm. He has since informed me that the tumour was a false aneurysm of a branch of the renal artery. The bladder was distended to about the size of two moderate fists. On removal its coats were found much thickened and there was severe cystitis. It contained three large partly decolourised clots, the largest of which resembled a good-sized kidney potato. There was also some broken-down blood and offensive urine. The left kidney was found to be in an early stage of interstitial nephritis.

Remarks.—A noteworthy point is that an accident comparatively so slight should have produced so extensive an injury to the kidney. The lad simply fell on the ground and did not strike his side against anything, neither the cartwheel nor anything lying on the ground, and there was no evidence of a rib being driven into the kidney. The eleventh and twelfth ribs were quite intact. The cessation of hæmaturia was most likely due to hæmorrhage in the loin, and to clots in the ureter, and when either, or both, of these causes of arrest of bleeding into the bladder were removed, hæmaturia recurred. During the latter stage anæmia was, doubtless, the reason for the cessation of bleeding. Hypogastric distension, pain, vesical tenesmus and ammoniacal urine indicated clots in the bladder and cystitis; lumbar fulness and tenderness pointed to blood in the loin and advancing inflammation; and abdominal soreness with rigidity of the right abdominal muscles, indicated incipient peritonitis by contiguity with the broken-down blood-clot and decomposing fluid blood in the loin.

The history of this case seems clearly to point to the following line of treatment in similar cases. Directly it is found that bleeding is not controllable after trial of every known means, and before the patient is too weakened by hæmorrhage, and also before septic phenomena have been allowed time to develop to an uncontrollable extent, a lumbar incision should be made over the kidney, and all clots, effused blood, and débris removed, and the cavity thoroughly cleansed. Then if it be possible to make out the remains of the kidney and to find the renal vessels and ureter, these should be tied and the renal remnants removed; but as in a case like the present, such a proceeding would be tedious and dangerous, the better plan would be to introduce a drainage-tube into the loin and perform anterior nephrectomy by incising the linea semilunaris. This being completed, the abdomen and pelvis can be cleansed if there be need, and the peritoneum on the posterior wall closely stitched up to shut off communication with the external opening into the loin. The abdominal wound is then to be closed and bandaged and external urethrotomy or lateral cystotomy performed, so as to empty the bladder of all clots, to wash it out, and to drain it. Though these three operations at one sitting seem severe, yet, under the circumstances, I do not

Digitized by Google

see what less would suffice. The lumbar incision and external urethrotomy are not major operations, and of themselves need cause no great anxiety; but when complicated with an intra-abdominal operation the risk would be undoubtedly greater, though not so great as through leaving the patient alone. The urethrotomy seems called for not only on account of the inflamed condition of the bladder, but also because vesical tenesmus might seriously interfere with recovery from an abdominal operation. I believe Mr. Rawdon has recorded a case of nephrectomy in a youth for ruptured kidney, in which the patient recovered from the operation, but died not long after from septicæmia, which the post-mortem showed was due to the condition of the lining of the bladder. This gives another reason for performing urethrotomy or cystotomy; for if the bladder be well washed out and drained the chance of vesical septicæmia is considerably minimised or even annulled, to say nothing of the great prospect of rapid recovery from cystitis, which in such a case it affords.

A few weeks since, assisted by Dr. Carter, and by my friend Dr. Crabb of Holloway, whose patient the lady was, I performed lumbar nephrotomy on the right kidney for pyonephrosis, and before operation we discussed the propriety of making a permanent opening per vaginam into the bladder to relieve the conditions of ulcerated mucous membrane and contraction and hypertrophy of its walls; but after passing a large drainage-tube into the kidney it was hoped that very little pus would pass into the bladder, and this was so. The inflamed lining of the bladder, however, secreted a large quantity of pus, and this condition of the organ gave much trouble after the operation. I mention this case here because it and other similar cases I have operated on teach the necessity of draining and resting the inflamed viscus, and also that most cases of pyonephrosis are complicated with cystitis of a very severe form, and that the treatment of this is as important as that of the kidneys.

Grosvenor-street, W.

ACUTE HYDRONEPHROSIS OR DILATATION OF THE PELVIS OF THE LEFT KIDNEY;

RUPTURE OF SAC AND EXTRAVASATION OF URINE INTO THE PERITONEAL CAVITY; OPERATION; RECOVERY.

By JOHN W. TAYLOR, F.R.C.S.,

OUT-PATIENT SURGEON TO THE BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.

As it is very rarely, if ever, so far as I am aware, that the abdomen has been opened for extravasation of urine into the peritoneal cavity, this case seems worthy of permanent record.

E. H——, a girl, aged fifteen, came under my care at the end of July, 1883. For a week or more she had been suffering from great pain in the left side of the chest and abdomen, with frequent vomiting. On examination I found a fluctuating tumour on the left side of the abdomen, midway between the ribs and pelvis. It was bounded above by the false ribs, below by the crest of the ilium, and a line of resonance about two inches and a half above Poupart's ligament: on the outer side it was lost beneath the muscles of the loin; on the inner side it reached to the middle line. On the morning of Aug. 1st the patient had a rigor, and the temperature rose to 101° F. Vomiting continued at frequent intervals. I diagnosed the case to be one of acute hydronephrosis; and, thinking that operative measures would probably be necessary, asked Dr. Savage to see the case with me. He kindly did so on the next day (Aug. 2nd), agreed with me as to the advisability of opening the abdomen, and we fixed on Aug. 4th for the operation. The next morning (Aug. 3rd) about 8 A.M. I received a message that my patient was dying. I saw her at 9 A.M., found her with legs drawn up, pinched and anxious face, crying out with pain, and constantly vomiting. She said that she felt as if something was "running away" from her. No external discharge, however, had taken place. On examination, I found the outline of the cyst had disappeared, but fluctuation was still more evident on the left side than on the right; the abdomen was generally distended and very tender. I saw that the cyst had burst, and that no time was to be lost, as the girl appeared to be rapidly sinking. I hastily arranged for immediate operation, to which Dr. Savage and Dr. Gosling kindly came. The latter gave ether for me. About 11 o'clock I opened the abdomen in the middle line, sponged out the urine from the peritoneal cavity, emptied what was left in the cyst with a trocar and cannula, as I could not find the point of rupture, and sewed the opening in the cyst to the margins of the incision, placing a piece of gutta-percha drainage-tubing above and another piece below the cyst-opening. The stitching the sac to the margins of the wound was the most difficult part of the operation, as it was exceedingly vascular and was with great difficulty prevented from tearing. At one part the passage of the silk suture caused a rent, and the sewing had to be repeated below this opening. The operation lasted rather more than an hour. The wound was dressed with absorbent wool, and an abdominal bandage applied, the patient being replaced in bed as soon as possible, with hot-water bottles to her feet and sides. On recovering from the anæsthetic the patient expressed herself as much more comfortable for the operation, and continued so during the remainder of the day. By the next morning, however, considerable peritonitis showed itself, and for two or three days there appeared to be but little chance of recovery. Matters, however, gradually improved; by the sixth the vomiting had ceased, the pulse, which had been very weak and thready, felt fuller, and a little flatus passed from the rectum. Some of the urine from the left kidney appeared to find its way into the bladder, as on several occasions it contained blood, and the patient complained of pain on micturition. I had not passed any drainage-tubing into the cyst, but had been content to sew the opening in it to the abdominal wall. As it had to be drawn considerably out of position to fix it in the middle line, I found that I had acted unwisely in not keeping the opening patent by tubing. After a week or ten days hardly any urine came from the opening, and the sac began to refill and enlarge with corresponding aggravation of symptoms. Knowing the thinness and brittleness of the cyst wall, I did not attempt to make any very forcible reopening of the original channel, but on August 18th made a second abdominal section to the outer side of the rectus, opened the cyst again, sewed the opening in the cyst to the margins of the incision, and passed in a glass drainage-tube. From this point the patient steadily improved. She has worn the glass tube ever since, passing urine freely through it. In this condition she remains at present. As soon as she was thoroughly convalescent I thought that matters might be made more clean and pleasant by corking the tube and allowing the urine to escape at intervals of three or four hours into a vessel instead of allowing it to constantly run away. But I found that this did not answer, slight rigors and pain returned, and the urine from the cyst, which up to this time had appeared occasionally to find its way into the bladder, from this date ceased to do so. This was inferred from the fact that the urine passed by the urethra had previously, at irregular intervals, been offensive—at these times containing a little blood and pus. From this date the urine passed by the urethra has remained perfectly free from any abnormality. I have not attempted any further operative interference since, except probing or sounding the channel to see if I could find any calculus. This was fruitless. For the last eight or nine months the girl has remained in very fair health, although her urinary fistula is of necessity a source of great discomfort to her. Every now and then the interior of the glass drainage-tube becomes encrusted and choked with deposited urine salts, when it has to be removed and cleansed out; otherwise no treatment has been required.

The following points seem worthy of notice in connexion with this case. 1. The advisability of immediate operation in similar cases where urine or other noxious fluid is extravasated into the abdominal cavity. 2. The possibility of success, although the operation may be incomplete. I did not find the point of rupture in the cyst, and therefore for three days mourned over my operation as logically incomplete and useless; nevertheless the emptying of the cyst and cleansing the peritoneal cavity were sufficient to bring about the recovery of the patient. 3. The question of further treatment. This seems to me to be a question of great difficulty. I think there is no doubt that the left ureter is now completely stopped, all the urine from the left kidney passing by the tube. Both kidneys are perfectly healthy and secreting freely. If the obstruction be a calculus, I cannot find it from the cyst, or the channel which is the remains of the cyst. If the obstruction be due to a valvular fold or coil of the ureters, as in several cases collected by Dr. Roberts of Manchester,

Digitized by Google

the only resource appears to be extirpation of the kidney. This, however, in addition to being a grave operation, is rather contra-indicated by the consideration that the abnormal tendency to obstruction would probably exist on both sides, and if a healthy kidney were removed there would be but little chance for the patient should obstruction at any time occur on the right side. Probably, if the patient became seriously dissatisfied with her present state, as I think is likely, and asks for something further to be done for her, the best course will be to make an exploratory incision in the loin, and if no calculus can be found, to remove the kidney.

In conclusion, I wish to add that my best thanks are due to Dr. Savage for his kindness in helping me with his presence and advice both at the time of the first operation and afterwards.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ROYAL HOSPITAL FOR WOMEN AND CHILDREN.

COMPLETE INVERSION OF THE UTERUS OF NINE YEARS' DURATION; REDUCTION BY AVELING'S REPOSITOR; CURE; REMARKS.

(Under the care of Dr. WILLIAM DUNCAN.)

FOR the following notes we are indebted to the resident medical officer, Dr. Sutherland:—

Mrs. H——, aged thirty-three, was admitted on Sept. 1st, 1884, complaining of constant flooding. She had always been a healthy woman till the present illness. Catamenia appeared when thirteen years old, her periods being regular. She was married at twenty-three, and has had three confinements. The first was premature, when eight months pregnant, "due to a fright"; the second was also premature, a year later, when seven months pregnant; the third was at full term, fourteen months after the second. She was attended by a midwife, and the labour lasted about two hours. After the child was born the patient says she "swooned away, and did not come round for some hours." She does not remember if she flooded then. About four days afterwards a large substance came away from her which she describes as being like "liver." She got up on the eighteenth day, but felt very weak. She suckled the child for eleven months, during the whole of which time she had a discharge, worse at times, principally blood, sometimes offensive. This discharge continued almost without intermission up to the time of admission, but was much more profuse every fourteen days, when she sometimes passed clots.

On admission she was well nourished, but very blanched from loss of blood. On examination a rounded smooth red mass, about the size of a large green fig, was found in the vagina. Its upper end was narrower than the lower, and the finger passed from its surface on to the vaginal roof without being able to detect any dip or groove whatever. There was no trace of the os uteri, and the sound could not be passed. Abdomino-rectal examination showed the absence of the uterus from its normal position, and the sound in the bladder could be made to touch the finger in the rectum without any difficulty. The mass could be drawn down to the vulva by means of a pair of vulsellum forceps. This caused no pain whatever, and then the finger in the rectum felt the round depression of the inverted fundus. The orifices of the Fallopian tubes could not be seen, as the vagina was very narrow, but two depressions (one on either side) were felt, and evidently corresponded with them.

Sept. 2nd, 4 P.M.—The cup of Aveling's repositor was introduced into the vagina, and a moderate amount of elastic pressure applied in the usual manner on the stem. A hypodermic injection of morphia (one-third of a grain) was given.

On Sept. 3rd the patient had slept well, and appeared comfortable. Temperature 99·8°; pulse 96. There was no hæmorrhage during the night, but for two hours a considerable amount of blood had been lost. The repositor was then found to have slipped in front of the uterus; it was replaced, and fixed not so tightly as before, and a few carbolised plugs were put into the vagina. The urine was drawn off twice by catheter. In the afternoon the repositor was removed, when the uterus was found to be *in statu quo ante*. After the vagina was well syringed out with carbolised water, the repositor was reinstated, the vagina plugged all round it, and considerable pressure applied, the patient being ordered to be kept under the influence of opium.

4th: The patient had a little pain during the night, but slept well. In the morning the stem appeared to have entered the vagina further, but was allowed to remain undisturbed until Dr. Duncan's visit. 4 P.M.: On removing the plugs the uterus was found not only to be completely reduced, but the cup of the repositor was in the uterine cavity, and the os uteri tightly contracted on the stem. The patient was placed under the influence of chloroform, the os dilated as well as possible by means of Barnes's bags, but even then great difficulty was experienced in extracting the cup, owing to a very tense ring of fibres which resisted the force of the hydrostatic dilators. The stem was unscrewed from the cup, which latter was then seized sideways with a strong pair of lithotomy forceps, and after considerable and prolonged traction it was extracted, but not before there was some tearing of the uterine fibres. Previous to this an unsuccessful attempt was made to divide the cup with strong bone forceps. From the laceration there was sharp arterial hæmorrhage, so the cavity was mopped out with a strong solution of iron. A hypodermic injection of ergotine (one grain) was administered, and the vagina was plugged with glycerine and iodoform. The patient was ordered to be kept well under the influence of opium. A third of a grain of morphia was at once given hypodermically, and a one-grain opium pill three times a day.

On the 5th she was comfortable but felt very low; looked excessively pale; some sickness; pulse 120, small; temperature 100°. Plugs removed and uterine cavity syringed out with a one in fifty carbolic solution at a temperature of 105°. Ordered five grains of quinine three times a day. In the afternoon she was free from pain but felt uncomfortably warm; temperature 102·4°; ordered two ounces of brandy, lemon-juice, and ice.

6th: Slept little during the night; was sick after taking some milk; no pain; syringed as before; morning temperature 101·4°; evening 100·8°.

On the 7th she felt better, having passed a good night. Only complained of sickness after taking milk. Ordered a nutrient enema every four hours of beef-tea and egg. Patient asked for some beer, so was allowed one pint daily. Uterus again syringed out, but the os was so contracted that a catheter had to be used instead of the ordinary uterine nozzle. Temperature, morning, 100°; evening, 101°.

On the 8th there was a great improvement, some colour appearing in her lips, and there was no sickness or pain. Fish allowed for dinner. This was retained and enjoyed. Vagina to be washed out twice daily and an iodoform plug inserted afterwards. Ordered a mixture with ergot and tincture of perchloride of iron three times daily. Temperature, morning, 100·8°; evening, 99°.

12th: Gaining strength and colour in face; uterus rather retroverted; replaced easily; length of cavity two inches and three-quarters. Not the least hæmorrhage since the uterus was reduced on the 4th inst.

18th: Patient practically well but still weak and anæmic; uterus normal in length and direction but the os was somewhat patulous.

Remarks by Dr. DUNCAN.—This case is a very interesting one, and teaches some useful lessons. 1. It shows the absolute necessity in every case of hæmorrhage from the vagina of insisting on making an examination, even though there be hæmorrhage at the time. Over and over again have women applied at the out-patient department with this symptom, and naturally refuse examination "as they are unwell." My rule is to prescribe an ergot mixture, and tell the patient that if the loss continue at her visit the following week, unless she then consents to submit to an examination I positively refuse to have anything more to say to her. The result is she sees the necessity and readily acquiesces. If medical men would make this a rule they will save their own reputations and their patients' health, and even life, in many cases, for it is by no means infrequent to see a woman

Digitized by Google

with cancer of the uterus, too far advanced perhaps for operation, whose life might have been prolonged for years if only her medical attendant had insisted on an early vaginal examination. The patient whose case I have recorded had been losing blood for nine years. She had consulted doctors both in London and the country, who prescribed physic until, as she says, she could no longer pay for it, and yet, inconceivable as it may appear, they did not attempt to find out what she was suffering from. Surely no language would be too strong to reprehend such trifling with this poor woman's life. 2. The diagnosis was easy, although the marked insensitiveness of the uterus when laid hold of with a vulsellum was a little deceptive, as it simulated the behaviour of a polypus under a like treatment. The unusual condition is, I think, explained by the chronicity of the inversion. 3. In any case of inversion of the uterus, where Aveling's repositor is used, it is highly important that frequent examinations of the position of the stem be made in order to avert the complication which occurred in this case, for there is no difficulty in removing the cup from the uterine cavity provided the os uteri be not given time to contract over it.

ANCOATS HOSPITAL, MANCHESTER.

CASE OF FRACTURE WITH DISLOCATION OF THE ASTRAGALUS; DEATH FROM PNEUMONIA ON THE TWENTIETH DAY; DESCRIPTION OF FOOT.

(Under the care of Mr. E. STANMORE BISHOP.)

JAMES H——, aged thirty-four, married, painter, on July 30th, whilst painting a wall, standing on a ladder thirty-six feet from the ground, felt the ladder slipping along the wall against which it was placed, and to save himself jumped off, coming to the ground upon his feet. He does not know whether his heel or his toes touched the ground first, but as he slipped and fell backwards, cutting the back of his scalp, it is probable that he lighted first upon the heel.

The patient was admitted about 5 P.M., when the scalp wound was brought together. He was suffering great pain in his foot, which presented the following appearances. On tracing down the tibia and fibula no fracture could be detected; the points of the malleoli were perfectly well marked, but the anterior line of the external one had not the defined outline of that of the other leg; there appeared to be some fulness anterior to it. The scaphoid tubercle could be felt in its normal position, and the distance between the base of the fifth metatarsal bone and the tip of the external malleolus was normal. The post-tibial and the dorsalis pedis arteries pulsated naturally, and the foot was warm. There was marked inversion and apparent shortening of the inner side of the foot, which was in the position of slight equino-varus. The skin was not broken, but the dorsum was much bruised and ecchymosed. There was crepitus on movement. On the dorsum, mainly outside the median line of the foot, and directly in the line of the medio-tarsal joint, there was a projection about half an inch wide, over which the skin was tightly stretched. It was bounded by straight lines behind and before, slightly converging outwardly, and on the inner aspect and to the inner side of the median antero-posterior line of the foot by another straight line at right angles to the two first mentioned. The fingers passed clearly down behind the projection, between it and the anterior surface of the tibia. The upper surface was smooth and bevelled off towards the outer side of the foot. The heel was slightly displaced inwards, forming with the leg an angle of 135°. The muscles were spasmodically contracted. Chloroform was given. The ankle-joint now appeared abnormally movable, especially inwards, and the foot could be drawn easily downwards in the axis of the leg. Crepitus was very distinct, and occurred on flexion, extension, abduction, or adduction. Extension in the axis of the leg being kept up, pressure upon the prominence in a direction backwards, downwards, and inwards caused it to disappear with a sudden movement, and flexion and extension could now be made easily, and apparently almost to a normal extent. The bruised skin was covered with collodion, and the leg put up on a back splint with footpiece at right angles and short side splints. The whole was then slung to the cradle.

On recovering from chloroform the patient expressed great relief from pain and perfect ease as regarded the foot, nor did he again complain of any pain there except from a bandage which was applied rather tightly some time after. This being loosened there was no further complaint.

Next day and for three or four days afterwards crops of bullæ rose on the dorsum of the foot, and on the outside of the heel, filled with serum, which were emptied and dried up. The foot remained warm. There was much troublesome constipation, and the patient was rather restive under confinement to bed.

All went on apparently well until Aug. 14th, when he became more restless, with dry tongue, quick and shallow breathing; temperature 102°. There was dulness on percussion over the right chest in front, over the two upper interspaces, and behind below the level of the sixth rib. He was ordered ten grains of an effervescent saline with ipecacuanha and quinine three times a day; whisky and milk, beef-tea, &c.

On the 15th the foot was easy, and on removing the splints appeared to be in good position, except that the extensor tendons were more prominent over the ankle than normal. There was no prominence in front of the bone in the place where it was felt at first. A large bulla on the outer side of the heel had been broken, and there was some superficial purulent discharge from the raw surface exposed. Foot quite warm. Temperature 103°. Breathing was still very rapid. The dulness had not increased. The patient had brought up some frothy sputum, tinged with blood.

16th: Temperature 103·4°. Breathing easier. More food had been taken, and the patient had slept a little. He complained of some pain in the chest, none in the leg. To have an enema for constipation.

17th: Temperature 103·6°. Breathing very quick and short. Tongue drier and browner in centre. To have chloric ether, ammonia, and ipecacuanha. Quinine to be continued, one dose of twenty grains given.

18th: Temperature 102·4°. Patient appeared rather easier this morning. No pain in foot or leg. No œdema; foot perfectly warm. Breathing very short, however, and dulness increased over the front of the chest; some dulness and pain on the left side. Patient not taking much food, but some whisky and milk. He became rapidly worse and died the same night.

Necropsy, eighteen hours after death.—As permission was only given to examine the leg, no other part was opened. An incision was made from the base of the fifth metatarsal backwards and curving round behind the external malleolus, ending two inches above its tip, another at right angles to this across the dorsum, and the soft parts reflected. These were infiltrated with dark blood, but there was no rupture of the extensor tendons or of the anterior tibial vessels or nerve. The extensor brevis was torn. The middle part of the external lateral ligament was merely a shred connecting the broken tip of the external malleolus to the os calcis; the anterior part was intact, but stretched and attached to the posterior fragment of the fractured astragalus. The dorsal calcaneo-scaphoid and the dorsal calcaneo-cuboid were ruptured entirely with the exception of a few fibres at the lower edge of the latter. The superior talo-scaphoid was torn through; but the internal talo-scaphoid was intact, and had acted as a pivot on which the anterior fragment of the astragalus had rotated. The strong internal lateral ligament of the ankle was intact, and the tendon of the tibialis posticus passing over it was in its normal position. The ligaments between the tibia and fibula were normal, and there was no sign of any attempt at separation between the bones. Of the bones, only the external malleolus, astragalus, and cuboid had suffered. The os calcis, tibia, scaphoid, and cuneiform were not injured. The external malleolus, a wedge-shaped piece of bone, the base external and involving the tip, attached by the posterior portion of the external lateral ligament to the posterior fragment of the astragalus, slightly by periosteum to the fibula, and by the remains of the middle portion of the external lateral ligament to the os calcis, lay pretty much in its normal position to the fibula, but behind the astragalus. The astragalus was divided into two main portions by a fracture which passed obliquely backwards and inwards, and from above downwards and forwards, along the line of the interosseous ligament, which was utterly destroyed. The posterior and outer fragment, which had given a feeling of fulness in front of the external malleolus, was attached to the external malleolus by the posterior and anterior portions of the external lateral ligament, the anterior portion of which, after the fracture of the posterior and inferior edge of the fibula, having carried it slightly outwards as it was jerked forwards by the original force. By the passage forwards of the astragalus, the posterior edge of the tibia and fibula were approximated to the os calcis, the

Digitized by Google

posterior ligament being intact and doubled in. The anterior and inner fragment, of which the articulating surface for the scaphoid had formed the prominence first seen, was attached solely by the internal talo-scaphoid ligament, and upon that as a pivot it had rotated in such a way that its anterior surface or head looked upwards, forwards, and outwards—its fractured extremity downwards, backwards, and inwards. A portion of its articular surface looking towards the internal malleolus was torn off and still attached to that bone by the internal portion of the deltoid ligament; by which, also, the fragment was retained in its normal position. The cuboid was crushed badly, lines of fracture extending through its external and anterior aspects, but its internal surface still articulated firmly with the external cuneiform and its posterior surface, though loosened by partial rupture of its ligament, from the os calcis, was uninjured.

Note by Mr. BISHOP.—As the fracture appeared to be reduced at the time, I presume that the movement of carrying the body from the ward to the mortuary after removal of the splints, which was done without my knowledge, reproduced the original condition. The case is recorded mainly in order to describe as minutely as possible the condition produced by the injury. The bones were removed, and are in the museum of the hospital.

Medical Societies.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

AT the annual meeting of the above Society, held on July 4th last, Dr. J. L. W. THUDICHUM, President, delivered an address. He said the Society might look back upon the session just ended with satisfaction and pride, and take from its success the assurance of a future in which its usefulness will increase and its importance develop. Their proceedings have not been tinged by the slightest discord; on the contrary, there had been a universal concurrence of goodwill on all sides. He had received from the officers, the council, and from the Society at large the most generous support. In founding the Cavendish Lecture the Council laid down the principle that it should be dedicated not only to medical but also to general philosophical objects. Perhaps it might be thought that a man whose life was mainly devoted to the elucidation of facts should not be made the patron of philosophical ideas; but this doubt will vanish when it is considered that such work as Cavendish performed is imperishable as well as luciferous. True, Cavendish remained an adherent of the doctrine of phlogiston to the end of his life, which occurred in 1810, at the age of seventy-nine. But stability was the tenour of his mind, and when he studied an object he seized it with tenacity, and held it as long as it yielded any results by the most varied treatment. Unlike Priestley, his great contemporary, he was of a retiring disposition, and several of his discoveries were not published early enough to secure him his well-earned priority. Many of the questions in chemistry, raised by Priestley's observations, Cavendish treated successfully as regards the discovery of new facts, although the phlogiston theory did not allow him to develop their correct bearing. But what he found allowed at once the truth to be seen, says Kopp, as soon as it was considered by an inquirer like Lavoisier, whose view was no longer dimmed by that splendid hypothesis. Cavendish confirmed Black as to the peculiarity of fixed air (carbonic acid), in 1766. In the same year he showed that the combustible air from metals is also a specific body. He found hydrogen by bringing zinc or iron in contact with dilute acids, and found stoichiometric relations: equal weights of zinc, with sufficiency of either of different acids, gave equal volumes of gas. Equal weights of different metals, zinc and iron, gave unequal volumes of gas; the relations of these to each other were estimated with remarkable accuracy. He found the burning air explosible when mixed with common air; he observed its lightness, a low specific gravity, as one-eleventh of common air (correctly, one-fourteenth). This led to the consideration of the specific weights of gases as a means of their distinction from each other. He dried his gases, and, when measuring this volume, observed pressure and temperature. He used mercury as isolating liquid. He examined, chemically, water from a London well (1767), and discovered incidentally the solubility of lime carbonate by an excess of carbonic acid. In 1783 he published an analysis of common air; this was so accurate that he stated air to contain 20·8 vols. of dephlogisticated air (oxygen), actually 20·9. In 1781 he investigated the cause of the disappearance of dephlogisticated air; the phenomena of the oxidation of metals, the combination of sulphur and phosphorus. When he exploded a mixture of combustibles with common air he obtained moisture; when he exploded two volumes of combustible with one volume of dephlogisticated air he also obtained moisture, and no air was left. Thus the composition of water was discovered. In 1875 he found the formation of nitrous and nitric acid by the agency of the electric spark. He retired from the active pursuit of chemistry after the new views had prevailed over the hypothesis of phlogiston. Let us hope that a future Cavendish lecturer may make his discoveries and their experimental illustration his subject. The speaker then alluded to the influence of Darwin on facts and theories, and deduced as the main result that our endeavours must be to establish firm data before constructing any far-reaching hypotheses or theories. In this endeavour our future is secure of results which will advance our science.

ACADEMY OF MEDICINE IN IRELAND.

AT a meeting of the subsection of Anatomy and Physiology, Professor J. M. Purser in the chair,

Mr. KNOTT read a paper for Dr. J. M'Donnell on the Development of the Eye in Vertebrata and its bearing on the Darwinian Theory. In the absence of the author, the paper was not discussed.

Mr. KNOTT read a note on a specimen of the Musculus Sternalis. He said he had some weeks before met with a bilateral specimen of the musculus sternalis of perfectly symmetrical arrangement. Arising from the cartilages of the third, fourth, and fifth ribs, and the edge and front of the sternum, it passed upwards to be blended with the sterno-mastoid of the same side. Twigs of the intercostal nerves were traced into it. The various homologies of this anomalous muscle which had been advocated by different authorities were then noticed; and, while admitting that each might satisfy the observers in certain cases, he feared that anatomists, in endeavouring to connect the structure in all cases with the same stratum or group of muscles, had fallen into the same difficulty as the travellers in the desert who came to loggerheads on the subject of the colour of the chameleon. He had no doubt that in the present case it could be more distinctly referred to the sterno-mastoid than to any other muscle. It was sometimes directly continuous with the rectus abdominis, and in others appeared, as in the series of specimens exhibited by Mr. Abraham, to be a part of the great pectoral, a view so ably advocated during the present session by Professor Cunningham. The idea of its relationship with the panniculus carnosus presented probably the greatest difficulties to its acceptance. Its depth of position, thickness of stratum, presence of strong tendinous extremities, and powerful attachment to bone were all against this hypothesis, which, the speaker thought, should be entirely abandoned. He believed that the anomalous muscle was of variable origin, and might in individual instances be referred to any of the other sources given, or even be a muscle *sui generis*, but the hypothesis of a community of origin for all the aberrant specimens described and figured by various observers under the name of musculus sternalis could not bear close investigation.—Professor CUNNINGHAM remarked that since he had first recorded the source from which the musculus sternalis receives its nerve of supply, he had been so fortunate as to meet with three additional cases. In all these the same nerve was found, although in two instances its continuity from origin to termination had not been fully made out. One of these cases he had mounted as a permanent specimen. He had traced the terminal twigs of the intercostal nerves into the musculus sternalis, but had always managed to follow them through it as they passed to the surface. In no case had he observed them giving filaments to the muscle. They pierced it in the same way as they pierced the pectoralis major. The argument which Dr. Knott adduced against the musculus sternalis belonging to the same group as the platysma could not be entertained for a single moment.

Digitized by Google

It was true that the platysma shows little or no bony attachment; but attention must not be confined to man, in whom this group of muscles is but feebly developed. In quadrupeds portions of the panniculus carnosus shows strong attachment to bone, and even in some cases are concerned in producing direct movement of the humerus at the shoulder-joint. Whilst repudiating this argument, however, he agreed with Mr. Knott in considering that the musculus sternalis has no relationship with the platysma myoides. He drew his proof from its nerve of supply.—Mr. ABRAHAM said the evidence of Mr. Knott was negative rather than positive as regarded the nerve supply, and Mr. Knott had not stated whether the specimen was dissected by himself or was simply shown to him after partial dissection and destruction by students. He corroborated what Professor Cunningham had said about his last muscle. The thoracic nerve was quite distinct.—Mr. KNOTT, in reply, observed that what Professor Cunningham was pleased to call "his proof" proved absolutely nothing, as the nerve supply from a common origin in some cases merely increased the probability that it belonged in those instances to the pectoral group, which had been fully admitted. With regard to the bony attachments of the panniculus carnosus, they could not for a moment be compared in strength and firmness of union with those of the deeper muscles. In reply to Mr. Abraham's remarks, he admitted that part of his evidence was negative, but he saw no reason to doubt that the muscle was wholly supplied in his specimen by the intercostal nerves. They were found entering the muscle and branching in it. Nothing more could be made out without microscopic examination.

Mr. ABRAHAM exhibited Six Chinese Skulls, concerning which he read a communication.—Professor CUNNINGHAM said he had measured the six specimens in Trinity College. These were casts, but still of course they served equally well for working out the cephalic index. All, with one exception, were in the mesocephalic group. One, however, was markedly brachio-cephalic, well within that group, which was a curious point.—Mr. ABRAHAM remarked that skulls of one race differed among themselves in every point, and valid results could only be obtained by taking a large series for comparison.

Reviews and Notices of Books.

The Science and Art of Surgery, &c. By JOHN ERIC ERICHSEN, F.R.S., LL.D., F.R.C.S., Surgeon Extraordinary to Her Majesty the Queen; Emeritus Professor of Surgery and of Clinical Surgery in University College, &c. Eight Edition. Revised and edited by MARCUS BECK, M.S. and M.B. Lond., F.R.C.S., Professor of Clinical Surgery in University College, London. Two volumes. London: Longmans, Green and Co. 1884.

A Manual for the Practice of Surgery. By THOMAS BRYANT, F.R.C.S., Lecturer on Surgery at Guy's Hospital; Member of the Council of the Royal College of Surgeons. Fourth Edition. Two volumes. London: J. and A. Churchill, 1884.

WERE the general merits and qualities of these two works less known and recognised the simultaneous issue of a new edition of each would afford a convenient opportunity for instituting a comparison and a contrast of their respective virtues and value. Happily (for the critic), this has now become a work of supererogation. Mr. Erichsen's treatise appears with the prestige of thirty years' approbation and success, and Mr. Bryant's manual with that of twelve years. The place of each in professional estimation is more or less permanently fixed; judgment has been given, the justice of which is not likely ever to be seriously impugned. It may at once be unreservedly said that each is, in its own peculiar way, pre-eminent, and that both are equally creditable to their authors, and indeed to English surgeons. So firmly are both these works established in public favour, that under ordinary circumstances it would perhaps have been enough to announce that Mr. Erichsen's had reached an eighth edition, and Mr. Bryant's a fourth edition: but the circumstances are not ordinary, at least, so far as concerns the former. What constitutes the chief peculiarity we shall consider presently. Without more ado we may here take leave of Mr. Bryant's book by congratulating the author upon the continued and increasing success of his work, adding the assurance that the new edition exhibits no abatement in the careful efforts to make the revision genuine and complete, and to keep it up to the level of the best contemporary knowledge. Novelties of fact and of suggestion have been discriminately recorded and intelligently criticised; previous utterances have been honestly reconsidered, and if necessary, expunged or amended, and at the same time no pains have been spared to give clearness and precision to every statement whether of deed or of doctrine. By its style and arrangement, by the comprehensiveness of its survey, and by the nature and quality of its subject-matter, both as to text and illustrations, and by virtue of embracing the principal specialties of diseases of the eye and the ear, the new edition of Mr. Bryant's work may be confidently recommended as an excellent manual for the student, and as a safe, sure, and not too garrulous guide for the practitioner to every department of surgery.

The circumstances under which the new edition of Mr. Erichsen's treatise makes its appearance are so altered and unusual that they will justify a more detailed and critical examination than it has been thought necessary to bestow on Mr. Bryant's new edition; indeed, they seem to demand it. For more than five-and-twenty years "Erichsen" has, in this country, been the most approved text-book on surgery for the abler or more advanced student, and the "liveliest pledge of hope in fears and dangers" for the practitioner; while its own intrinsic merits, conjoined with accidental and extraneous circumstances, have secured for it the honour of being the chief, if not sole, representative of English surgery abroad. Time, which has brought deserved fame and honours to the author, has likewise enhanced the reputation of his works, and now, in spite of the appearance of powerful competitors and rivals, "The Science and Art of Surgery" stands as high in professional favour and confidence as at any period of its existence. But time and honours have their drawbacks; famous men have scanty leisure, and tasks which they were wont to accomplish single-handed call at length for coadjutors. So it has happened to Mr. Erichsen, for though still evidently keeping control and supervision over the main character of his work, he has deputed to Mr. Marcus Beck the labour of preparing a new and revised edition. Not that this is the first time that Mr. Erichsen's work has had the advantage of Mr. Beck's learning and literary skill, but it is the first time that this gentleman's name has appeared on the title-page as the avowed and responsible editor. This notification presumably implies a greater scope and licence to the editor than heretofore, though the original author (in his preface) remains surety and sponsor for the whole.

It is needless to remark that Mr. Beck's editorship affords at once a substantial and sufficient guarantee that the revision has been conscientiously and painstakingly performed, and that everything that is best and everything that is newest in surgical knowledge and literature has been laid under contribution. And as a matter of fact it would be difficult to praise too highly the greater part of the work that more obviously proceeds from Mr. Beck's head and hand. Every page shows marks of his improving touch, of his wide knowledge, his rich experience, sagacity, and research. The illuminations of his knowledge and intelligence is, however, most conspicuous in the domain of pathology, and more especially in those places that take in the facts and doctrines of inflammation, of septic and infective diseases, and of surgical diseases of the kidneys and other urinary organs. It would be surprising if, in a work so extensive, no error or mistake should occur. Doubtless some of both

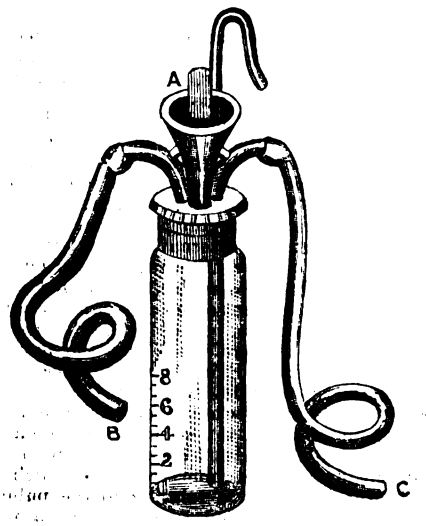
Digitized by Google

may be found. In the interpolated historical notice of the operation of amputation, for example, it might be objected that the description of the Hippocratic plan of dealing with a gangrenous limb is misleading if not positively incorrect; that the title of James Yonge's work is given as "Currus Triumphalis e Terebinthino" instead of "Currus Triumphalis e Terebintho"; that Guido de Cauliaco is called "Guido di Cauliaco"; that the name of the English surgeon Lowdham, who was one of the first to suggest the plan of cutting a flap, is several times given as "Lowndham." These are, however, comparatively unimportant and venial faults. We may confidently repeat the conviction that Erichsen's "Science and Art of Surgery" will continue to hold its place as the best exposition in the English language of those branches of surgery with which it deals.

We should have been glad if we could have ended this notice of Mr. Erichsen's new edition in a strain of unqualified approval and praise; but the requirements of critical justice will not so easily be satisfied. And, first of all, we must enter a protest against the mercilessness with which every succeeding edition is augmented in bulk. The seventh edition contained nearly four hundred and thirty pages more than its immediate predecessor, and now the eighth edition contributes a further addition of four hundred and fifty (allowing for the omission of the chapter on Eye Operations), making an aggregate increase of nearly nine hundred pages in two editions. If this tendency is not checked, "Erichsen" will soon become impracticable for most students. To the student of these days there is a serious meaning in the adage *Μέγα βιβλιον μέγα κακόν*, which freely translated is "a big book's a great nuisance." Already the student shows a willingness to adopt the expedient of "cramming" the smallest manuals that pushing teachers and enterprising publishers can be found to supply. It is useless to oppose this tendency unless authors will learn to distinguish between *addition* and *edition*. What an example did Syme set in this respect. Each succeeding edition of his work is said to have got fuller of matter and smaller in size. Doubtless it is a hard and not altogether agreeable task for an author to erase what a few years before he had prepared with such approving pains; but it is still harder to make the student a victim of an author's complacency, want of leisure, or literary vanity. It is unreasonable to expect a student to read two thousand three hundred and thirty-four pages of a work which deals with general surgery only, and which compels him to seek his knowledge of the literature of diseases of the eye, the ear, and the skin from separate and special works. This is a view of the matter we earnestly commend to the consideration of Mr. Erichsen and his colleague. We do not advocate the introduction of chapters dealing with the diseases of the eye, the ear, and the skin; we merely plead in the interests of the student that the rest of the volumes should be correspondingly reduced in bulk; and when we speak of the interests of the medical student, we mean, in the case of Mr. Erichsen's work, the interests of surgical education.

Turning to the second chief fault of the new edition, it is impossible to ignore an alteration of tone and temper as regards some controversial matters. In speaking of the preceding edition of Mr. Erichsen's work, we said: "There are no random statements, no scientific fopperies, no dallyings with fashionable pathological doctrines merely because they are fashionable." It would not be possible, without considerable reservation, to repeat this language. For example, there is no concealing the fact that the state of mind in which the question of "Listerism" is now considered is no longer the judicial and impartial state to which Mr. Erichsen had accustomed us, but rather that of indiscriminate partisanship. We do not for a moment wish to question the truth of the doctrine that underlies the method of "Listerism," nor to gainsay the alleged success of the plan. It would be altogether out of place to do so here, even if our faith were less than it is. What we disapprove relates neither to the truth nor the error of this or that theory, but only to an extravagance of language unbecoming a scientific exposition. We need only to mention to condemn them such terms as "absolute prevention," "perfectly," &c., in speaking of "Listerism," and the "very uncertain" or "fails completely" of rival modes. The use of such terms is perilous alike to those who employ them and to those who read or hear them. How perilous the following may show. The treatment of fractured patella by opening the joint and wiring the fragments is thus spoken of (vol. i., p. 613):—"In this country it was first suggested by Lister as being free from danger, provided strict antiseptic treatment was adopted. ..... The operation has been performed now a considerable number of times, and *all recorded cases have so far been successful*" (the italics are our own). This statement is allowed to appear in September, 1884, or ten months after the discussion at the Clinical Society of London, and after a special and detailed report (which appeared in our columns) of a fatal case due to septicæmia in King's College Hospital, in spite of strict Listerian precautions (THE LANCET, Nov. 17, 1883, pp. 856 and 860). About the time that the subject of fracture of the patella was being debated at the Clinical Society, we announced that M. Chauvel, in a discussion at the Société de Chirurgie, had referred to a collection of thirty-eight cases, four of which had been done without antiseptics, before the year 1877. Out of the thirty-eight cases there were twenty-eight good results, and ten were not successful. Three deaths were recorded, two from septicæmia and one from carbolic acid poisoning; and in one case amputation had to be performed (THE LANCET, Nov. 24th, 1883, p. 917). The truth seems to be that on the score of mortality alone the treatment of fracture of the patella by wire suture is nearly as hazardous as the operation of ovariotomy. The climax of enthusiasm is, however, reached in the following passage: "However much the details of the *Antiseptic Method* may be varied in the course of time and by the introduction of new chemical agents, the grand principle which sub-lies [*sic*] it, and on which the whole superstructure of its details is built, will run on intact and unchangeable. ..... The Principle [with a capital P] itself is immutable" (vol. i., pp. 3, 4). This is Finality indeed. It reads like a dictum of a modern Athanasius, and one looks instinctively for the words, "Which Faith except everyone do keep," &c. Mr. Erichsen had already told us that the operative part of surgery had attained almost finality, and we believed him; and now Mr. Beck (are we right in saying so?) assures us that the science of surgery has also reached its utmost limit. Must we believe this too? How does an "immutable" principle work in other departments of natural science? Take optics, where the data are most numerous and least conflicting. There is almost an overwhelming amount of evidence in support of the truth of the undulatory theory of light, but did it ever enter into the mind of Thomas Young or of John Herschel to declare this theory "intact, unchangeable, and immutable"? The last-named philosopher laid it down that "the grand and indeed only character of truth is its capability of enduring the test of universal experience and coming unchanged out of every possible form of fair discussion." Has this so-called "immutable" principle underlying "Listerism" stood this test? Does it compel the universal assent of scientific experts? Are all practising surgeons convinced of its truth? Mr. Bryant is far more modest in forecasting the future: "In fact, it may now be said that the Listerian mode of dressing has had its day, though the principle upon which it is based survives, and is likely to do so" (vol. i., p. 58). It is, however, but fair to state that Mr. Erichsen (for the sentence

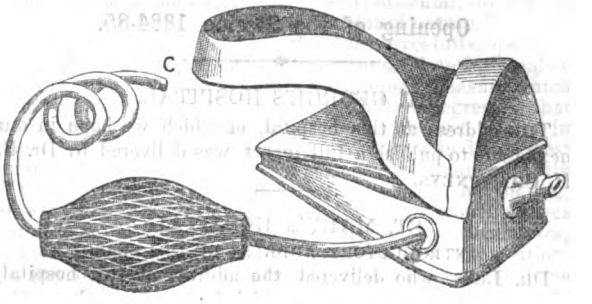
Digitized by Google



must be his), with characteristic good nature, is unwilling to abandon all non-Listerians to the pains and penalties of helplessness and despair. He tells the surgeon, "If he is not in the land of 'spray-producers,' 'protectives,' and 'guards' of iodoform and salicylic acid wools, let him not despair—cold water and clean linen rags will do much to supply their place." These are gracious words; from them all heretics and unbelievers may draw courage and consolation, and in them will we rest and be satisfied.

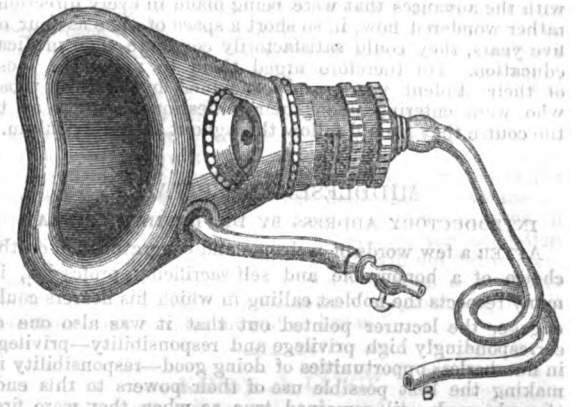
New Inventions.

A MODIFICATION OF DR. JUNKER'S INHALER.



WHATEVER may be the future of the agent commonly called bichloride of methylene, or shortly methylene, I do not propose to discuss here. The valuable memoir of Reynauld and Villejean must go far to shake the belief of those who regard the preparation commonly sold in England as anything but a mixture of chloroform and alcohol. In the meantime there are many who prefer that anæsthesia should be induced by methylene, and this is especially the case with ovariotomists. Dr. Junker's inhaler has long been used as a convenient one for the exhibition of methylene, but those who have used it at all largely have found that it has several drawbacks which go far to restrict its use. Practical experience of its use and shortcomings has led me to attempt to remedy these; and the modified form that Messrs. Mayer and Metzler have constructed for me answers its purpose well, and obviates all the disadvantages of Dr. Junker's

FIG. 1.



apparatus. In all prolonged operations it is necessary to refill the methylene receiver, an act accomplished with delay and difficulty in the older apparatus, as the top has to be unscrewed and readjusted. This, unless the narcosis is profound, will allow the patient enough air to partly regain consciousness—a result harmful to the patient and the operator. In the old method both hands were engaged, so that the pulse could be but imperfectly studied, while the conjunctival reflex could be tested with difficulty. Further, the administrator often found himself greatly inconvenienced in other ways for lack of a free hand. In the modified form refilling can easily be performed by the administrator himself. The celluloid stopper is removed from the feed-hole (A, Fig. 1), the methylene introduced, and the celluloid peg simply fixed by a turn of the fingers. The second difficulty, that of using the hand-injecting bag, is obviated by employing the flat-faced pedal. The straps fix this firmly to the foot, allowing the administrator to step from one side of the table to the other, if needful. The tube C (Fig. 2), of course, as in Dr. Junker's, supplies air which is forced through the receiver bottle, while Fig. 3 shows the two ends of the tube which conveys the air-diluted vapour to the face-piece. The coils of tubing have been omitted to save space in the drawing. It is important that the inlet tube should be upon the upper surface of the pedal, otherwise it becomes choked with dirt. In my inhaler I have replaced the rigid face-piece, which I have found cuts and incommodes the patient, by one made of leather and having an air cushion adjustment around its face surface, which enables one to fit it very accurately to the inequalities of the countenance. This is

FIG. 2.

supplied with an expiration valve allowing for free disposa of respired air. I find that it is quite easy to have a series of face-pieces of varying size, which may be so arranged as to either get into gear with Clover's ether inhaler or my methylene inhaler, and thus dispenses with the necessity of having a double set of face-pieces. Further, the face-piece can be removed entirely and replaced by a V-shaped tube which screws on. To the limbs of the V are attached soft

FIG. 3.

catheters, which answer admirably for giving the anæsthetic in operations about the mouth, in which, of course, a face-piece cannot be employed. The catheters pass right to the back of the nares, and so throw the vapour into the pharyngeal cul-de-sac about the larynx. I find Mr. Milles employs a somewhat similar contrivance.

DUDLEY W. BUXTON, M.D., B.S., M.R.C.P.,
Administrator of Anæsthetics at the Hospital for Women, Soho-square.

HOSPITAL SATURDAY FUND.—At a meeting of the board of delegates of this fund, on the 27th ult., it was stated that the total of the last street collection would probably prove to be, when various outstanding amounts were received, about £2800; and seeing that this, notwithstanding the wet weather which prevailed last Hospital Saturday, was £500 in excess of the 1883 collection, the idea of having a supplementary collection had been abandoned. The managers of the fund intend carefully to consider the advisability of the collection being made in June or July, instead of early in September, on account of the greater prospect of fine weather on the earlier date.

KILLED ON THE RAILWAY.—Mr. Thomas Williams L.R.C.P. Ed., whilst walking on the railway between Mold station and his residence was knocked down by a Chester train and killed instantaneously. Deceased was between seventy and eighty years of age.

Abstracts
OF
INTRODUCTORY ADDRESSES
DELIVERED AT THE
MEDICAL SCHOOLS OF LONDON
AT THE
Opening of the Session 1884-85.

ST. GEORGE'S HOSPITAL.

THE address at this hospital, of which we hope in our next issue to publish a full report, was delivered by Dr. F. H. CHAMPNEYS.

ST. MARY'S HOSPITAL.

INTRODUCTORY ADDRESS BY DR. LEES.

DR. LEES, who delivered the address at this hospital, referred to various comments which have been made on the subject of introductory addresses to medical students, in which the remark was made that they were sinking into lower depths of commonplace and platitudes, but, in reply to that statement, he observed that such addresses were not intended for the general public, but for the students alone. Those who addressed them had been students, and they wished to impress upon them that art was long and time was fleeting. They who knew something of the extent and variety of knowledge which it was needful for them to acquire, and found it difficult for themselves to keep pace with the advances that were being made in every direction, rather wondered how, in so short a space of time as four or five years, they could satisfactorily complete their medical education. He therefore urged them to make the most of their student years, and concluded by advising those who were entering upon their professional studies as to the course they should follow throughout their curriculum.

MIDDLESEX HOSPITAL.

INTRODUCTORY ADDRESS BY DR. DAVID W. FINLAY.

AFTER a few words of welcome and congratulation on the choice of a honourable and self-sacrificing profession, in many respects the noblest calling in which his hearers could engage, the lecturer pointed out that it was also one of correspondingly high privilege and responsibility—privilege in numberless opportunities of doing good—responsibility in making the best possible use of their powers to this end. Cicero's words still remained true as when they were first uttered:—"Homines ad deos nullâ re propius accedunt quam salutem hominibus dando." What constituted, as it appeared to him, the chief attraction of the medical profession was that it satisfied both the intellectual and sympathetic side of our nature, for while the field for acquiring experience and also for research were boundless, the results arrived at were made directly serviceable in the treatment of our fellow-men, in relieving pain, in restoring function, and in saving life. A wide field was open to them for its exercise both at home and abroad. But no prosperity or distinction, nor anything else worth having, would be gained without honest and steady work, and he besought those especially who were commencing their curriculum to make a good start by cultivating habits of application and industry and method from the very beginning of their studies. He would urge upon them all the sentiment contained in one of Ovid's couplets:—

"Quæritur Ægisthus quâ re sit factus adulter
In promptu causa est; desidiosus erat."

The idle man's mind was open to attacks of all sorts of folly, and temptations to idleness and worse than idleness abounded in every large city. There was no surer way of keeping clear of all such entanglements as might lead in the end to moral loss and wasted lives than to have their minds preoccupied with something that was good and useful. Habits of idleness were too often acquired in the first year, and if the subject of them ultimately made up for lost opportunities it was only after a grievous expenditure of time and irksome labour. He did not propose to say much as to the way in which they should study particular branches, but with regard to anatomy it was hopeless to expect to acquire any useful knowledge without regular and careful dissection; and he would warn his hearers against the error of supposing that demonstrations could ever take the place of personal acquaintance, if he might so put it, with the parts of the human body themselves. In this, as in all other departments of knowledge, they must remember that—

"Study is like the heaven's glorious sun,
That will not be deep search'd with saucy looks."

He would also remind them of the paramount importance of physiology and pathology, and the necessity of unremitting attendance in the post-mortem room, where they would see and handle the results of disease.

In addressing them last year his predecessor had expressed the hope that by this time the long-looked-for Medical Bill would have become an Act, but this hope had not been realised, and legislation seemed further off now than it was then. And if they regarded the mischief that had been and was likely to be worked on the Bill of compromises actual and proposed before it arrived at its last surviving stage, they need not perhaps greatly regret that the vessel had foundered before reaching port. At the same time all the labour expended upon it and the daylight which had been let in upon some of the licence granting bodies had not been fruitless. Many of the corporations had been led to set their houses in order; and a scheme for the conjunction of the two Royal Colleges of London for the purpose of granting qualifications would probably soon be put in force, in accordance with which they would have only one examining body to face in order to gain a double qualification. If by some change in their constitution these bodies could only obtain power to confer degrees in medicine and surgery, the scheme would be complete; but there were always vested interests and difficulties to be overcome in the way of all such reforms.

No one contrasting the state of medical science now with what it was twenty, or even ten, years ago could fail to see that in this, as in other things, they lived in an age of progress. In illustration of this he might point to the discoveries which had been made in the field of bacterial pathology; to the development and extension which had taken place in connexion with abdominal surgery; to the greater precision which had been given to diagnosis in the matter of cerebral localisation; and, as regarded therapeutics, to the rapidly extending antipyretic treatment of febrile diseases, both by internal and external remedies. And in the domain of preventive medicine or public health, no less activity had been observable. He was led to refer more in detail to this department of medicine, mainly on account of its growing importance, because it had been brought so prominently before the profession and the public in connexion with the Health Exhibition, and because students, as a rule, appeared unwilling to give it the attention which it deserved. In pleading for a greater amount of attention to this department of study, it would be a strong argument if it could be shown that a notable diminution in the death-rate had already resulted from the work which had been done under the various Acts relating to the public health. The lecturer then proceeded to show that a remarkable decline in the general death-rate of England and Wales had indeed taken place, especially since 1875, the year in which the great consolidating and amending Act relating to public health had been passed, illustrating the point by charts which showed a fall from 22·8 per 1000 of population in 1875 to 18·9 in 1881, and 19·6 in 1882. Figures were also adduced to show that the total number of lives saved above the average of the ten years 1866-75 amounted to no less than 329,000. An argument was also drawn from the diminished mortality of the late cholera epidemics which had visited this country in favour of the claim made on behalf of sanitary organisation. Certain zymotic diseases were then referred to and compared with each other, the decline in mortality of those which were regarded as most preventable tending to proof in the same direction. A further argument was furnished by a comparison of results in the case of rheumatism and diseases of the respiratory system on the one hand, and typhus and enteric fever on the other, charts being referred to which showed that there was no average tendency to decline in mortality in the case of the former, while in the latter there was an almost unbroken progress downwards from first to last. Other considerations also pointed to the same conclusion;

Digitized by Google

and taking all together, they were such as to compel the belief that in the main improved sanitation and the advance of the country in the ways of health stood to each other in the relation of cause and effect. But there must be no resting in the conflict with disease and dirt, and they might cherish the hope of as great an advance in the future as there had been in the past. There was plenty of good work yet to be done, and opportunities were likely to occur in the practice of everyone. It must not be forgotten that there was personal as well as public hygiene, and that even inculcating cleanliness and the value of ventilation upon those classes of patients who were little likely, without such teaching, to be impressed with their importance, would not be done in vain. But even with the most sanguine anticipations realised, disease, like the poor, would always be with us. Hence curative medicine would always retain its importance, and there was surely room for improvement also here. With increased precision in diagnosis, which they might hope for, they must attain to more successful therapeutics. "In conclusion," said the lecturer, "let me say that there are noble traditions connected with the school which you have chosen as the home of your study; where, to speak only of the illustrious dead, Sir Charles Bell, Campbell de Morgan, and Charles Murchison have laboured and taught, and we look to you to keep those traditions bright and to reflect credit upon your foster-mother and your profession wherever your lot may be cast. If I may repeat anything I have said it would be to urge you again to earnest work; remembering that whether your talents be ten or one you will have to give an account of the use you make of them to a higher than any earthly power, and that although 'art is long, life is short.' In the words of the oldest and best of text-books, 'Whatsoever thy hand findeth to do, do it with thy might; for there is no work, nor device, nor knowledge, nor wisdom, in the grave, whither thou goest."

In the course of the address a sympathetic tribute was paid to the memory of the late Dr. J. Hall Davis, who had for more than twenty years held office in the Middlesex Hospital and School; and reference was made to the loss sustained by the cause of preventive medicine in the comparatively early death of Mr. Netten Radcliffe, one of the most indefatigable and ablest workers in the field of epidemiology.

WESTMINSTER HOSPITAL.

INTRODUCTORY ADDRESS BY DR. HUGHES BENNETT.

AFTER congratulating the students on the honours they had won, Dr. Bennett remarked that it was prudent for those about to enter on a practical career to pause at the outset to consider the ultimate object for which they now strived, and to endeavour to determine whether the means they employed were calculated to attain the end desired. It was stated as a general axiom that the final aim of every human being, considered from a worldly point of view, was to extract the largest possible amount of felicity from his existence. How this aspiration was to be best secured has always been a matter of individual opinion; and various and innumerable are the attempts which have been made to effect its consummation. The accumulation of money forms a common means by which mankind strives to reach the goal; but it was admitted that the mere acquisition of fortune did not by itself conduce to that true happiness and contentment of spirit which it was the ultimate hope of humanity to realise. To reach this end, besides mere sensuous gratification, the intellectual cravings of man must be satisfied. It may therefore appropriately be asked how far the profession of medicine affords a suitable sustenance for temporal wants and at the same time supplies intellectual occupation and gratification, the successful combination of which two elements is undoubtedly necessary for the attainment of happiness. Whatever personal qualifications deserving of respect the physician may possess, from his calling itself he gains little prestige. There is no item in the expenditure of a household more grudgingly bestowed, more liable to be questioned, or more tardily settled than the doctor's bill. There is no vocation so imposed upon, so largely called on to perform gratuitous labour, or so unthankfully acknowledged as that of the medical man. If the claims of the medical profession to public recompense and private fortune are inadequately recognised, its followers must look to another source of satisfaction as an equivalent for all their sacrifices. This, if properly sought for, will be found in the study of medicine for its own sake, in the appreciation of its intrinsic merits, and in its cultivation as a science. The truth of the axiom that knowledge of all kinds brings with it its own reward has been amply demonstrated. From the earliest ages, and among all nations, the search for and the acquirement of information have always been regarded as a source of fascination to the intellectual mind. If this is true with regard to learning in general, it applies with augmented force to the study of science in particular, for dealing as this does with the positive phenomena of nature, it affords facilities for the culture of all the faculties, gives full scope to the imagination and every opportunity for the display of originality and invention. There is probably no human pleasure which is so permanent, or which reaches so lofty a degree, as that which emanates from an ardent and successful career in scientific research and discovery. Medicine in its highest sense may be looked upon as a science. It treats not only of the prevention, relief, and cure of disease, but of life, growth, and decay, in all their bearings. Its scope involves not only the administration of remedies for abnormal states, but an acquaintance with the structure and composition, the physical and vital properties, of all substances. Medicine may, in short, be said to be that science which attempts to fathom the mysteries of life and death. This opens out a boundless and inexhaustible field of inquiry to him who searches after mental occupation, and offers an endless supply of material, which if properly cultivated cannot fail to return an abundant harvest of intellectual fruit. These considerations are all the more important when it is remembered that the path of advancement is steeper and more thorny to-day than ever before in the history of the world. Never was competition in every calling so fierce, and never did prosperity, even in a moderate degree, demand for its attainment such a union of physical and intellectual qualities. It cannot therefore fall to the lot of all to meet with great prosperity in life, and the man who is most to be pitied under failure is he whose happiness and misery entirely depend on such outward circumstances. On the other hand, he who is in love with philosophy will think lightly of sufferings and privations which to another would be intolerable. If such a one is poor in one sense, he may become affluent in another by the acquisition of valuable mental endowments, for, as Shakespeare says, "It is the mind that makes the body rich." Those therefore who deliberately embrace an intellectual career, who are imbued with the tastes which harmonise with its pursuit, and who possess the education necessary for its successful cultivation, will not fail to recognise those higher capabilities of the profession of medicine which offer such ample opportunities of gratifying in all directions every form of mental ambition.

KING'S COLLEGE.

INTRODUCTORY ADDRESS BY THE REV. DR. WACE.

AFTER some introductory personal remarks, in which reference was made to the baronetcies recently conferred upon two members of the staff, Sir W. Bowman and Sir Joseph Lister, Dr. Wace offered some observations on an aspect of medical work which it was the honour of King's College to bring prominently forward—namely, the union which their organisation established between their medical school and other departments of education, and the manner in which they were thus led to realise how closely they were all bound together in that great work of human culture and civilisation which was the immediate purpose of a liberal education for any profession. More lives were wrecked and careers disappointed by moral than by intellectual failures. "Mens sana in corpore sano" was a good maxim; but he had heard men quote it with much satisfaction whose whole attention was directed to the sanity of their bodies. Their profession would instruct them how to keep a sound body; but they could not safely disregard others if they would keep a sound mind. The address concluded with some congratulatory remarks on the position of the department and with a welcome to the new students.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

INTRODUCTORY ADDRESS BY MR. DYER.

THE inaugural sessional address was delivered by Mr. THISELTON DYER, who remarked that his own experience

Digitized by Google

of the examination room, if it brought some satisfaction, brought some disappointment. He could see clearly enough now why it was so—viz, paying too much attention to some things and neglecting others. In checking this tendency to wander about the fields of knowledge, which ought instead to be systematically tilled, the ordeal of an examination is not to be despised. The grammar of a science must for practical purposes be as thoroughly and laboriously learnt as the grammar of a language.

CALENDAR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THIS annual compilation has just been published by the Council of the College; from it we make the following analysis:—It appears that there are no less than 1166 Fellows on the *rôle* of the College, of whom 611 obtained the Fellowship by examination, five were elected as Members of twenty years' standing under Section 5 of Charter 15 Vict., and three are *ad eundem* Fellows. There are 16,509 Members. The Licentiates in Midwifery remain at 969; the Licentiates in Dental Surgery number 553.

The Board of Examiners in Anatomy and Physiology consist of nine members, annually elected by the Council from the Fellows of the College. It conducts the Primary Examinations in Anatomy and Physiology for the diplomas of Fellow and Member, and during the past Collegiate year has held eight meetings for the Fellowship, and forty-seven for the Membership; at the former there were 134 candidates, of whom only 56 passed, 78 being referred for six months. For the Primary Examination for the Membership there were 1108 candidates, 733 of whom passed, whilst 330 were referred for three months and 45 for six months. The fees received from candidates for this examination amounted to £61397*s.*, of which sum the Board received £2618.

The Court of Examiners consists of ten members, also elected by the Council from the Fellows of the College, all of whom, however, are members of the Council, except Dr. Humphry. During the past year the Court has held two meetings for the Fellowship, and forty-five for the pass examinations for the Membership. At the former there were 45 candidates, 30 of whom passed, 15 being referred for twelve months. For the Membership there were 804 candidates, of whom 348 were successful and 303 were rejected. The fees paid by the candidates amounted to £10,431 5*s.* The fees paid to the Court amounted to £4707 12*s.* The Board of Examiners in Dental Surgery has held three meetings for the examination of thirty candidates, twenty-two of whom received their diplomas. The sum of £346 10*s.* was paid by them in fees, of which the Board received £110 5*s.*

The income of the College from all sources during the past year amounted to £22,111 10*s.* 9*d.*, derived principally, as already shown, from fees paid by candidates for the diplomas of the College—viz., £16,917 7*s.* Rents from chambers produced £1530 18*s.*; fees paid by Members of the College on admission to the Fellowship produced thirty guineas; dividends on stock yielded £1182 19*s.* 3*d.*; from members of the Council and Court of Examiners on their election, £63. The expenditure of the year amounted to £20,046 7*s.* 4*d.*, the largest item being in fees paid to members of the Court and the Board of Examiners—viz., £7435 17*s.* The next largest amount appears in salaries and wages for the officers and servants of the College in the three departments of the library, museum, and office—viz., £3784 14*s.*; taxes, rates, diploma stamps, and insurance absorbed the large amount of £1469 9*s.* 3*d.* In the extraordinary expenditure, £700 was devoted to honoraria to Dr. Goodhart and Messrs. Trimmer and Doran. Under miscellaneous items, £431 11*s.* 6*d.* appears as having been expended, leaving a balance at the bankers of £2965 3*s.* 5*d.* The metropolitan hospitals are represented on the Council by Messrs. J. Cooper Forster (President), T. Bryant, and A. E. Durham, of Guy's; St. Bartholomew's, by Sir J. Paget, W. S. Savory (Vice-President), H. Power, and T. Smith; St. George's, by Mr. T. Holmes (Vice-President); University College, by Messrs. Erichsen, Marshall, C. Heath, and M. B. Hill; King's College, by Sir J. Lister and Mr. Wood; the London, by Mr. J. Hutchinson; the Middlesex, by Messrs. J. W. Hulke and G. Lawson; St. Thomas's, by Sir W. Mac Cormac, Messrs. J. Croft and S. Jones. Sir T. S. Wells, Bart., and Messrs. W. Cadge, W. Allingham, and E. Lund are not attached to any of the recognised metropolitan hospitals. The oldest Fellow of the College is Mr. J. M. Arnott, F.R.S., a late President of the College, who was admitted a Member so long ago as April 4th, 1817.

THE EPIDEMIC IN KIDDERMINSTER.

THE epidemic of enteric fever in Kidderminster has continued during the past week, but some abatement in its severity has now shown itself. The last reports, especially, show that the number of fresh attacks has undergone diminution. The visit which Dr. Parsons paid to the town, on behalf of the Local Government Board, was singularly brief in view of the magnitude of the epidemic, a circumstance which probably finds its explanation in the fact that the department is undermanned as regards its medical staff. The general impression which has been gained is that Dr. Parsons viewed the water-service and the relation of one of the wells to the sewage farm with grave suspicion in connexion with the origin of the epidemic, and the measures of precaution which may be taken in order to exclude any possibility of water-pollution will need to be based on skilled investigation of all the conditions liable to affect the well in question. No official report has, as yet, been issued.

At a meeting of the medical profession, held on September 26th at the Town Hall, present Dr. Roden (in the chair), Mr. S. Stretton, Dr. Langford, Messrs. D. Corbett, J. W. Colbourne, J. L. Stretton, and Dr. Measures, a prolonged discussion ensued, with minute investigation of all circumstances having bearing upon the causes of the present epidemic, when the following resolutions were unanimously agreed to:—1. That while we are unable to state positively the cause of the epidemic, we are of opinion that it was primarily caused by the water-supply, and that it has been aggravated by the imperfect drainage system and other insanitary conditions, and that there is no evidence against the milk-supply. 2. That from the evidence produced we are of opinion that the well at the sewage station should be closed immediately, and not used again under any condition whatever. 3. That proper provision should be made for the certainty of pure water in the reservoir, including the raising of the surrounding wall, and the adoption of a proper covering. 4. That immediate steps be taken to provide an additional supply of pure water at a distance from the town. 5. That the drainage system be investigated by an eminent sanitary expert; all levels, catch-pits, and ventilations to receive his especial attention. 6. That all junctions with the main sewers be examined, and certified as being in rigid order by the corporation officials. 7. That a public abattoir be constructed without delay, and that all intramural slaughter-houses be abolished. 8. That all middens and privies be abolished, and that no pigsties be allowed in the close confines of the borough, and that some measures be taken to investigate the emanations from obnoxious trades. 9. That in the meantime the free use of disinfectants should be proceeded with, including the flushing of all drains, and the watering of the streets with the same. 10. That the infectious hospital be placed at the disposal of the medical men for the admission of all cases they consider desirable, and that such admission be obtained with the greatest possible ease. 11. That a thousand handbills be printed for distribution amongst fever cases, with suggestions for the care of the patients, nursing, disinfection of secretions and linen, proper feeding, and dealing with the milk and water supply. That a fund be started for the provision of sick nurses, to devote their time to visiting the sick poor, under the direction of the medical men.

At the same meeting a letter was read from the borough member, J. Brinton, Esq., expressing his deep regret at the suffering of those afflicted with typhoid fever, and enclosing a cheque for £20 towards the subscription to provide nursing relief, under direction of the medical authorities.

THE LANCET.

LONDON: SATURDAY, OCTOBER 4, 1884.

IT is scarcely possible that the Medical Council can on the 6th inst. hold a purely formal meeting, or one for the mere election of a President. It has to face an altered state of facts as compared with those of any recent period. The legislation which has been long expected has not been realised. Not only has it not been realised, but the circumstances of failure are significant, and constitute a subject for the serious attention of the Medical Council. The Council has never been considered very ardent in its desire for medical reform, except on one point. But on this point it has generally been consistent. The point we refer to is the necessity for the creation of Conjoint Boards. Since the time of the famous inquiry into medical education, when Professor PARKES and Professor SYME took so deep an interest in the whole question of examinations, the one subject on which the Council has given a public-spirited and decided vote has been the consolidation of the bodies for licensing purposes. The following is the resolution of the Council, on Feb. 26th, 1870, moved by the late Dr. THOMSON, and seconded by Dr. (now Sir RISDON) BENNETT, and agreed to by a majority of seventeen to one, that one, of course, being the late Sir DOMINIC CORRIGAN, who dearly loved to be in a small minority:—

"That this Council is of opinion that a Joint Examining Board should be formed in each of the three divisions of the kingdom, and that every person who desires to be registered under any of the qualifications recognised in Schedule A to the Medical Act shall be required previously to such registration to appear before one of these Boards and be examined on all the subjects which may be deemed advisable by the Medical Council, the rights and privileges of the Universities and Corporations being left in all other respects the same as at present."

On the 28th of the same month a further resolution was agreed to, on the motion of Dr. PARKES, seconded by Dr. ANDREW WOOD, to the effect that the Universities and Corporations in each division of the kingdom should be requested to concert a scheme for the formation of such a Board.

These are the fundamental principles of the Medical Council in regard to the basis of new medical legislation. They accord with the views of thousands of the profession, ascertained over and over again by memorial even *ad nauseam*. They have been endorsed by a Royal Commission. They have been adopted by every Government for fourteen years, including the present Government, which in two successive sessions has embodied them in a Bill, which Bill was on the eve of passing when a mine was sprung affecting the very fundamental part of the Bill, in the form of an amendment by Sir LYON PLAYFAIR, giving power to the Medical Board in any division of the kingdom to accept in lieu of a final examination under a Conjoint Board the examinations of a University, or of two or more Corporations, provided (*a*) that the Medical Council shall be satisfied, and (*b*) that in every substituted examination a number of examiners not exceeding half the total number of examiners shall be appointed by the Medical Board.

The Medical Bill, like many other Bills, perished under the weight of talk, chatter, and obstruction which now degrade Parliament, and take the place of legislation; but it was not concealed that the Ministers in charge of the Bill were prepared actually to abandon the principle of compulsory conjoint action on the part of existing authorities, and to agree, under the pressure of Sir LYON PLAYFAIR, to a system by which a great multiplicity of licensing authorities would be maintained; and to bolster up such a discredited system by creating new examiners to watch the work of the old ones, doubtless at the expense of the profession, who already pay too heavily for their examining mercies.

This is the *terminus ad quem* of all the efforts of the Medical Council and of successive Governments to establish a sound Conjoint Scheme in each division of the kingdom. And this is the altered situation in which the Council finds both itself and the questions upon which it and its best committees have spent so much of their time. It would be outrageous to create more examiners, when the very grievance is that we have too many already. The new examiners must either be maintained at the expense of the present examining bodies, in which case they will not be independent; or at the expense of the unfortunate students, who are already heavily mulcted in the process of becoming qualified, and who have a right to look to the Medical Council to protect them from further exactions. We cannot believe that the Council will view the existing situation with satisfaction. There may be sections of it which see in the present failure of legislation some security for the continuance of privileges which have no foundation in reason or in the respect of the profession; but the disinterested members of the Council who have at heart the true interests of the profession will see only the perpetuation of weak bodies, tempted by the love of money to trade on their high functions, and of a Medical Council incapable of controlling them, and increasingly at the mercy of the representatives of the lowest bodies. Under all these circumstances we look forward with anxiety to the action of the Council, and of those members of it which represent its best traditions.

ADVOCATES as we have ever been of the much deplored custom of delivering inaugural addresses at the opening of the winter session, we see good cause for satisfaction in the series of addresses which have been given this October. It would not be easy, perhaps, to enumerate the reasons for the scoffing manner often affected when any suggestion, however remote, is made of repairing to the theatre where an introductory address is to be delivered. It is obvious that we are now referring to the average man and the average lecture; naturally a great name will infallibly attract an audience. One of the reasons for the *nil admirari* tone of the scoffer at inaugural addresses may possibly be found in the superior intellect of the jeerer; a superiority of mind, however, which fails to appreciate not very subtle differences and an excellence which some among us may regard as of morbid origin. We cannot be accused of seeing the beautiful where it does not

Digitized by Google

exist if we assert that a study or perusal of the introductory addresses as a whole is not altogether unprofitable. It has occurred to us to get some impartial competent person of education—a perfect stranger to all concerned—to read all the addresses, and then to infer what manner of man the author of each inaugural address might be. Such a task would possess not a little interest and curiosity. The address which has given us most cause for meditation was that delivered by Dr. GOWERS at University College. Both in form and matter the oration was of a type and an excellence all its own. Nor did it lack a humorous aspect. "Your coach may carry you through the lofty portals of Lincoln's-inn and Pall-mall, or the lower archway of Blackfriars, and leave you altogether unfitted for independent progress. Your grinder may pass you through his mill with such success that you emerge a flabby mass of factitious atoms, kept in the semblance of form by the sack of a diploma," &c. The importance of deliberate and conscious effort in attaining to relative perfection in the art of observation was urged on his hearers, and the value of the practical study of anatomy, histology, and botany as aids in the development of the art of observation, was insisted upon. Another and very different province, in which self-training was rightly regarded as desirable, was the cultivation of conscious sympathy with suffering, at least to the extent of enabling the doctor to enter into the feelings of the sick, and, in a degree, into their modes of thought. The value of medical work to the community and to the State was another subject on which Dr. GOWERS spoke. Attempts to estimate in money the worth of the lives that are saved by the medical profession might be made, but the data are too imperfect to show more than how large it is. However, at the lowest estimate, it was computed that half a million of deaths were prevented every year. The most philosophical section of Dr. GOWERS' address was that in which he dealt with the part played by disease in the physical progress or degradation of the human race. Whether the influence of our art upon the race is to promote its physical deterioration or not is of course an open question. But there is one side of the question which may fairly receive consideration. It cannot be denied that the genius of progress has stamped a higher value on the products of cerebral action as compared with more purely muscular power. The subject is an intricate one, and requires more space for elucidation than we have now to spare. But it is obvious that so long as the vital forces are kept in action in the body of a hypothetical man who possessed the most useful and the most excellent mind, so long would that man be of more value than any single individual, and therefore more worthy of preservation. The survival of the fittest is a law as unalterable as any other law of nature. The phrase has, however, frequently been misconstrued. "The great doctrine of the survival of the fittest is less a law that has to be proved than an axiom, as self-evident as that two straight lines cannot enclose a space," as Dr. Gowers puts it.

Sir J. RISDON BENNETT delivered a thoughtful and able inaugural address at St. Thomas's Hospital, commencing with a saying of Dr. JOHNSON, that "to judge rightly of the present we must oppose it to the past." The various and ever-varying mental manifestations of patients were pointed out as a fit subject for earnest study. "In the more strictly scientific departments of the investigation of disease—etiology, diagnosis, and prognosis"—mental manifestations are of great moment. Sir RISDON was of opinion that many more of our most important diseases than we have hitherto imagined owned not merely a nervous but a strictly mental origin. Indeed, perhaps the most valuable portion of Sir RISDON'S lecture related to the unfolding of his thoughts on the agency of the mind in the production of disease and in the recovery from illness. A remedy might owe a large portion of its beneficial effect to the mental state of the sufferer. It has become almost proverbial to have faith in one's doctor, one's remedies, and one's good luck. And we are not so taken up with the demonstrable that we cannot understand how mental effort may exercise an influence for weal or woe.

In writing an address for such a composite assemblage as may be found on the opening day of the medical session, it is an almost impossible task to please everybody. There is no denying the fact that an oration which sparkles with cheerful, not to say light, thoughts is by common consent that which takes for the nonce; though it is no less true that when perused afterwards, as many addresses are, its intrinsic worth may be not so great as that of one which was less brilliant in delivery. At St. George's Hospital Dr. CHAMPNEYS gave a lecture which for a judicious combination of merry wit and sound sense, certainly could not be surpassed. "He was undecorated, except by the judgment of the highest court of appeal, that of his peers," a sentence used in the eulogy of Mr. CÆSAR HAWKINS, has something in it which recalls the vein of humour one is accustomed to encounter at the Savoy Theatre. Some good advice was administered at the Middlesex Hospital by Dr. FINLAY, who touched upon most of the topics which now interest medical science. Dr. LEES, at St. Mary's Hospital, read an instructive address which commanded much attention; and the meeting at the Westminster Hospital listened to the words of welcome and knowledge which Dr. HUGHES BENNETT uttered. At King's College, the excellent address by the Rev. Dr. WACE abounded with appropriate similé, and was received with acclamation.

THE friends of the Hospital Sunday Fund have much reason to be thankful to Mr. JAMES LANE for raising the one question possible as to the advantage of Hospital Sunday to the great cause of hospital support. Has the establishment of Hospital Sunday had the effect of diminishing the number or amount of personal subscriptions to individual hospitals and dispensaries? It has often been surmised to have this effect; and Mr. LANE, in a happy moment, set about analysing the facts of St. Mary's Hospital, and, as he thought, proving that while it had received from the Fund £600 a year more than it used to get from local church collections, it had lost annually in donations, during the time of the Fund, £1745. Mr. LANE'S letter was the more valuable as written in a tone of moderation, and with obviously no ill-will to the Hospital Sunday Fund. The next day, however, *The Times* published a letter by Mr. BURDETT in answer to Mr. LANE. It was not so much an answer as a very complete and through finishing of that which Mr. LANE had only begun—viz., the analysis of the facts. It is so easy in hospital matters to make round statements and to arrive at hasty conclusions, but it is difficult to go deeply into

Digitized by Google

facts. Mr. BURDETT, however, comes to close quarters with the facts of the case, and completely pulverises the conclusions at which Mr. LANE had too hastily arrived, by showing that the defection in later years of the subscriptions to St. Mary's had other and ample explanations without any reference to the Hospital Sunday Fund; amongst others, that in the earlier period, prior to the establishment of the Hospital Sunday Fund, an anonymous and generous donor was sending £1000 a year to the hospital, which ceased in 1873. Then during the first decade very strenuous exertions were made by the hospital to raise funds to defray the expenses of new buildings; also that during that period a Hospital Fund dinner was annually held and very actively promoted, so that it yielded an average income of £1280 a year. This source of income has been allowed to dwindle, till now nothing remains of it in the hospital accounts but an average annual expenditure of £86 put down to the festival dinner. Mr. BURDETT completes his destruction of Mr. LANE'S statistics by showing that, comparing the subscriptions of the two decades, the falling-off in the latter one is only £31 per annum. Unless Mr. LANE can show that the loss of the munificent annual donation of £1000 was due to Hospital Sunday his discomfiture is complete, and it only remains for him to be thankful that the Hospital Sunday Fund has made the financial position of the hospital better by £600 a year than it would otherwise have been.

The fact seems to be this—that the older and more established hospitals are a little defective in energy and ingenuity. The very establishment of Hospital Sunday may have increased this defect, by making them feel less self-reliant. Their claims are magnificent and unanswerable; but times are bad, and claims of all sorts are multiplying, so that even charitable men readily find excuses for not supporting hospitals. The Hospital Sunday Fund is the best friend of hospitals. It stamps with religious sanctions and considerations the case and the claims of hospitals. We do not mean that the Council has yet achieved what it ought to achieve. It is too self-complacent. It makes one annual effort, and then folds its arms in satisfaction and does nothing more to raise the sunken condition of medical charities for another year. It needs to be roused to much more effort and ingenuity in the use of its great influence. By all means let it be criticised, and that severely. But it is destined to remain an institution to remind rich men of every church and synagogue that their sick brother is in their keeping, that they have to make his bed in his sickness, and that if they fail to do so an ominous and crowning condemnation will be heard—"I was sick, and ye ministered not unto me."

No one—and least of all Dr. KOCH himself—could have imagined that the discovery he declared of the specific choleraic organism would be accepted without challenge. Nor could it be expected that in a matter of such universal interest the public mind should not be awakened by the intelligence of this discovery, and should be keen to follow the arguments and facts adduced against it. We have already spoken of the conclusion arrived at by Dr. LEWIS, and of the detection by Drs. FINKLER and PRIOR of Bonn of the "comma bacillus" in cases of sporadic cholera. This was made a subject for discussion at the Scientific Congress at Magdeburg, when it was stated by Dr. FINKLER that KOCH himself admitted the morphological resemblance between the organisms he found in Asiatic cholera and those found by FINKLER in cholera nostras. It is possible to admit this, as well as Dr. LEWIS'S facts, without materially affecting the standpoint assumed by KOCH. Again, we learn by a telegram to *The Times* last Monday that the English Commission is already at work at Bombay, and that Dr. KLEIN, to testify his utter disbelief in the specific nature of the comma bacillus, had swallowed the cultures. Might it not be possible that the ingestion of the bacillus itself does not suffice to induce cholera in a healthy man? The experiment has been made before, quite apart from any question of a bacillus. Does every human being who is exposed to the source of infection take the disease? We can imagine Dr. KOCH reproaching his fellow-scientist with having performed an experiment without fulfilling all the conditions necessary to ensure its success. For KOCH himself is careful to point out that there must be disposing conditions to account for the manner in which the cholera develops; and would be prepared to receive the intimation that the bacillus can be swallowed with impunity without his faith in his discovery being shaken. Then we have the elaborate report of the French Commission, which whilst admitting the presence of the comma bacillus, denies its pathogenic property, and seeks for changes in the blood as the initial cause of cholera—a statement supported by inoculation experiments. That the blood is profoundly altered, and that this alteration is the main cause of death in this disease, few will deny; but Dr. KOCH may well reply that the effects of choleraic poisoning have here been mistaken for causes, and he will not be unsupported in such an assertion. For our own part, we must endeavour to keep an open mind on the question, and leave it to those who are engaged in the actual research to reconcile their differences as best they may. We may, however, venture to express the hope that our English Commission will not rest content with a demonstration of the fallacies of Dr. KOCH, but will search diligently in every direction for a solution of the problem which can explain the facts of the disease in an even more satisfactory manner than he has done.

Annotations.

"Ne quid nimis."

THE OPENING OF THE WINTER SESSION.

ONCE more the cumbrous wheel of medical education has finished its annual revolution, and once again the well known cycle has commenced its usual course. Would that the beginning of the new session had taken place under the auspices of a new Medical Act! But, alas! fate has destined otherwise. Everywhere we see around us the old familiar signs of activity at the schools and hospitals. The faces of first year's men, strange in the new light which has dawned upon them, are to be seen side by side with those of the older students, ready, if not eager, for new work in new departments. The members of the medical and surgical staffs, too, greet one another and the students with kindly looks and genial manner. It is in the first few days of the new session that the mind really appreciates the value of the long vacation. Everything seems for a while to wear a new aspect, though we feel at the same time that there has been no real change.

The teaching at our hospitals and schools is a theme

Digitized by Google

on which we may say a few words. Our students want more teaching and less coaching. Growth of memory requires repression in favour of development of reason. Clinical work is perhaps the department in which students display most ignorance at the final examinations, and unfortunately a premium is still placed, even in the higher examinations, on mere book work. Clinical knowledge can only be gained by long and patient observation, and two years is too brief a time even when the student is most diligent and gifted. We do wish that students would leave their books and visit the wards. And where the students are, there should the teachers be also. Every school ought to have clinical professors who can afford the time for exposition, and it naturally follows that the junior members of the permanent staff are, on the whole, the most competent for the posts of clinical teachers. What we have urged in connexion with medicine and surgery holds good also of the teaching of chemistry, physiology, and anatomy, with th ir related subjects. Students as a mass do not work half enough at their dissections, their physiological demonstrations, or their histological preparations. Any humble but wise student who happens to have spent his time in the more practical paths of his career cannot help inwardly blessing the influences which led him to see for himself rather than trust to the descriptions of other observers. Such a one may not come off brilliantly at examinations, but he has no cause for despair. Patience and perseverance after, on the same lines as before, qualification cannot fail to raise such a one, whether he stay in town or go into the country or elsewhere, to the highest dignities which his profession is able to confer. He may be patronised for a while by his more brilliant (at examinations) *confrère*, but the time will surely come when the latter will own the former's worth. We have not the least wish to cry down success at examinations. Far from it. Experience has shown that many of the examinationally distinguished are also those who have gained their knowledge from direct observation; but at the same time it cannot be denied that many who have obtained the highest honours at examinations are sometimes failures in later life. In harmony with the preceding thought, we would urge all who can avail themselves of the time and money to spend as long a period as possible in their education over and above that required by the different examining boards. We are not entirely in agreement with those people who believe that the future general practitioner should make haste to rid himself of his hospital ways. There is time enough for this alteration, with the average student, after he has completed his medical studies. After he has obtained his diploma, let him for a time, if possible, continue his clinical studies. Indeed, most of us have heard "men" say that they learn far more real medicine and surgery after being qualified; and the reasons for this plain statement are not far to seek—excessive book work, the result of over-examination, being the main one.

A PREMIUM ON INFANTICIDE.

"A PREMIUM on Infanticide" is the not too sensational heading of a most forcible and faithful letter written by "M.R.C.S. Eng." to the Editor of *The Times*. We have frequently had occasion to deplore the excessive loss of infantile life. Whilst approving for the most part the arguments contained in the letter referred to, we should yet be inclined to take exception to the opinion that infant mortality, so excessive and unnatural, cannot be satisfactorily accounted for. It seems to us that most of the causes of this excessive mortality may be said to be fairly well known to medical men, though probably not fully appreciated by the public. The case which "M.R.C.S." regarded as typical of the [illegible] will undoubtedly find its parallel in the practice of every observant practitioner. The system of insuring infant life may justly be stigmatised as pernicious, as it virtually places a premium on the destruction of infant life. It is true that the "policy" of insurance falls through if the infant perish within a period of three months, but such a limitation is certainly an insufficient and ineffectual protection against crime. Nor do we think that it is always insurance money with tempts to the commission of infanticide. The poor labourer who finds himself burdened with many children feels most acutely the misery which a large family entails. If he be an honest, sober man the difficulties of making both ends meet are well nigh insurmountable; how must it be then if the breadwinner be thriftless and intemperate? Under such circumstances opiates, disguised as "soothing syrup," "carminative," "cordial," and even laudanum itself, find a ready sale. Further, the sale of patent medicines is totally unrestricted, and these nostrums are dangerous weapons indeed. Being advertised in a reckless fashion as "perfectly harmless," these patent medicines, to all appearances approved and commended by a Government stamp, find an easy sale in large and poisonous quantities. The "accidental" administration of a fatal overdose of the compound relieves the parents of further responsibility and the insurance office of a small portion of its wealth. The difficulty of remedying this state of affairs is unquestionable. An insurance system providing against the natural exigencies of infant life cannot be wholly condemned, and, indeed, with proper precautions may be made to be much more a blessing than a curse. One path at least is clear, and that is the application of certain restrictions to the sale of every patent medicine the composition of which is at all doubtful.

SANITARY CONDITION OF CALCUTTA.

SINCE we last brought to the notice of our readers the very unsatisfactory condition of Calcutta, from a health point of view (THE LANCET, Aug. 23rd), the differences between the Lieutenant-Governor and the municipal corporation have widened and given rise to the necessity for action on the part of the Government. The offer made by Mr. Rivers Thompson to appoint a mixed committee, of which the corporation should be represented by two of its members, for the purpose of drawing up a scheme for the sanitary and structural improvement of the town and suburbs, was rejected by the municipal body as being impossible for them to accept "without an entire loss of self-respect." Mr. Harrison, in his capacity of chairman of the Commissioners, addressed to the Lieutenant-Governor a letter which fills eight columns of the *Englishman*, in which he discusses the grounds upon which the necessity for such a committee was presumed to be founded, and puts forward a claim for the Commissioners that they had done already more than they were required by the Act to do, and that none of their acts furnished any justification for the appointment of a committee by the Lieutenant-Governor. In a very able letter, from the Secretary to the Government, the various points advanced by Mr. Harrison are considered, and the opinion of the Advocate-General as to the legality of the course followed is given. In consequence of the refusal of the corporation to join in the appointment of a mixed committee, the Lieutenant-Governor, in the exercise of the power vested in him by Section 28 of Act IV. (B.C.), has appointed a committee consisting of the Sanitary Commissioner of Bengal, a member to be appointed by the Commissioners, and the Hon. H. Beverley of the Bengal Civil Service, who are to report, before Dec. 1st, "Whether they are of opinion that the cleaning and the conservancy [illegible]

Digitized by Google

town are defective to an extent likely to be prejudicial to the health of the inhabitants of the town, or of any part thereof; and if they shall be of such opinion, shall specify in their report what further provision should be made for the cleaning and conservancy of the town up to the end of the year 1885–86, and shall submit an estimate of the cost of the said further provision." On the publication of this Order thirty-two of the Commissioners resigned their seats at the board. The other Commissioners were anxious that their chairman, Mr. Harrison, should represent them on the committee, but he declined to do so, and after some discussion, it was resolved to ask the Town Council to nominate a member. It cannot but be matter for regret to all who take an interest in the sanitary condition of one of our great Indian cities that the Municipal Commissioners should have persevered in their refusal to take adequate measures for the protection of the population, and especially the poorer members of it who are unable to protect themselves, against the ravages of preventable diseases. We have gone very carefully through the published correspondence, and have come to the conclusion that the Lieutenant-Governor was bound to take action in the matter, that the course he proposed in the first instance was one which ought to have met with support from all who were entrusted with the superintendence of the health concerns of the city, and that the duty of putting in force the provisions of the Act was forced upon him by the refusal of the Commissioners to make adequate and suitable provision for the cleansing and conservancy of the town. We trust that the result may be the preparation by the Committee of such a scheme as may meet with the support of all classes and prove effectual in reducing the amount of sickness and mortality among the population of the city and its suburbs. That great and immediate improvement is necessary must be admitted if the description by the health officer be correct of the water-supplies in some of the localities in Calcutta, that they are "twice as bad as London sewage," or if it be true, as stated in an official document, that the inhabitants in some of the plague spots in the city "live their lives in the midst of filth, sleep on filth, bathe in filth, drink filth, cook in filth, and wash their clothes in filth."

MODERN MUMMIES.

A SUBJECT which has important bearings on the vexed question of cremation was broached at the recent meeting of the Social Science Congress, in a paper by Mr. Thomas Bayley of Birmingham. In spite of much that has been said and written to the contrary, the practice of burning the dead must, in our opinion, and as we have stated elsewhere, lack the sanction of law so long as it does not afford a further guarantee than that required in cases of burial that death has not resulted from foul play. The paper alluded to recognises this difficulty, and proposes a plan by which it may be met. It is the following. The bodies loosely but completely enveloped in cotton-wool, and placed within air-tight cases, are exposed, in a subterranean gallery lined with cement, to the action of cold air, which is chemically dried, and purified by filtration from putrefactive bacteria. After a time dry air at a higher temperature is used in the same way. The result is mummification, the integument remaining white. Bodies which have undergone this process may, it seems, be kept for an indefinite period without evidence of change, if protected from damp; may, if required, be submitted to examination by analysis or otherwise in an adjoining cool and dry mortuary chamber; may be cremated or otherwise disposed of. Mr. Bayley's plan has considerable merit on the ground of its philosophical ingenuity. We are not informed whether its efficiency has been practically tested. If experiment should prove that it is a trustworthy safeguard, one solution of the judicial difficulty has certainly been found. At the same time, we cannot but think that the advocates of cremation would find the addition of a complex preliminary process of mummification a hindrance rather than a help to the working of their own system.

PERIODICAL CHANGE OF COLOUR OF HAIR.

A YOUNG girl, aged thirteen, of an idiotic type, was admitted into the asylum at Hamburg on April 1st, 1880, and died there in 1882. At the age of three years she began to be affected with spontaneous movements like those of St. Vitus' dance, which were chiefly confined to the head and upper limbs. Between her fifth and sixth year she had become the subject of well-marked epilepsy. She was able when four years old to run round a table, but her powers of progression steadily diminished and the lower limbs passed into a condition of chronic stiffness. When in the asylum of Dalldorf (Hamburg) she had epileptic fits about every eight or fourteen days; besides, it was observed that she experienced alternations of agitation and calmness, each of about a week's duration. In the period of agitation the turgescence and redness of the face were most pronounced, the pulse was full, the skin warm, and actively transpiring, at the same time that the mental condition was one of extreme obstinacy. Further, it was often remarked that the colour of the hair underwent decided changes; sometimes it was blond and at others red, whilst the depth of these colours also varied. The alterations in colour occurred in the brief space of two or three days; the first appearance of change was observed at the free ends of the hairs; the same tint of hair persisted for seven or eight days. Each of these periods of change of colour of hair coincided with a phase of agitation or sedateness. During the state of excitement the hair always had a red colour, whilst pending the phases of stupidity the blond tint prevailed. The case appeared to be one of genuine pathological change. The paler hairs differed from the darker ones only in the presence of more numerous air spaces. The structure of the brain and spinal cord was much altered.

HONORARY HOSPITAL SURGEONS IN BOMBAY.

THE appointment of unpaid or honorary surgeons to the Goculdas Tejpál Hospital in Bombay, to which we called attention in THE LANCET of November 2nd, has proved a complete failure. In January last the Surgeon-General with the Government of Bombay called upon Surgeon-Major Hojel, the medical officer in charge of the hospital, for "a full report of the working of the system of supplementing the hospital staff by unpaid or honorary surgeons," which had been under trial for upwards of eighteen months. Surgeon-Major Hojel reported very unfavourably, his chief complaint being of great irregularity in the hours of attendance of the honorary surgeons, "who come and go as they like, and as a consequence the work is performed very perfunctorily." His remonstrances on this subject, as responsible head of the hospital, made both verbally and in writing, were unheeded, and he was in consequence obliged to "take the house surgeon from his legitimate work in the hospital and send him to prescribe for the out-patients," who were waiting for the arrival of the honorary surgeon. As regarded two of these gentlemen, Surgeon-Major Bonstead fully confirmed this report of irregularity in attendance; the third was on leave during the time he was in charge. These reports having been brought by the Surgeon-General under the consideration of His Excellency the Governor, he was pleased to direct that Mr. Blaney and Mr. Pesikáka should be reappointed for a further term of six months. The Surgeon-General was directed to inform

Digitized by Google

these gentlemen that although their services are gratuitous, it is not the less necessary that they be rendered under rule and with scrupulous observance of punctuality; and the surgeon in charge of the hospital was to be requested "to fix the hours of attendance of the honorary assistant-surgeons, and to report if they are not observed." Mr. Khamkáta, who had been reported as the most unpunctual of the three, was not reappointed. We understand that the two gentlemen who were reappointed have since resigned. There has been much violent abuse of Mr. Hojel in the local press for the unfavourable report he made on the subject; but we fail to see how he could have done otherwise when called upon by the head of his department to state his opinion and the grounds on which it was formed. The Government of Bombay was evidently satisfied with the manner in which he discharged this disagreeable duty, as they refused him permission to take legal proceedings against any of the papers which had maligned him. We trust that it will now take the necessary steps to appoint an adequate and efficient paid staff to this hospital. In the interests alike of the profession and the patients we desire to see the surgical appointments filled by men of superior qualifications, who will devote their best energies to the treatment of the poor entrusted to their care, and will give to their professional brethren the results of the observations which they may be enabled to make in such a wide field as that afforded by the practice of the Goculdas Tejpál Hospital.

THE DIAGNOSIS OF GASTRIC DISEASE.

WE have frequently called attention to a prolonged investigation, which is still in progress, on the mensuration of organic nutrition, especially in relation to diseases of the stomach, by M. Rommelaere. This chemist and physician has come to definite conclusions concerning the amounts of urea, chlorides, and phosphates discharged by the urine in cases of gastric disease, conclusions which warrant, in his opinion, the diagnosis of this or that affection of the organ in question. His latest contribution deals with the discharge of phosphates in the urine in cases of simple ulcer of the stomach. In this affection, when healing, he finds that the "azoturia" is rather more than usual, which excludes the diagnosis of cancer; the "chloruria" is normal, and so is the "phosphaturia." It will be remembered that Dujardin-Beaumetz and others have not confirmed Rommelaere's results concerning the amount of the discharge of urea in cancer of the stomach. Dealing with the discharge of phosphates in the urine, the author believes that there are two varieties of hypo-phosphaturia—one due to inefficient alimentation; the other consequent on the retention of phosphates in the economy. The first variety has not much significance from the point of view of diagnosis. When hypo-phosphaturia is lasting, the prognosis of the case of gastric disease is very grave. The clinical importance of hypo-phosphaturia is only of value in cases where the patient is not starved by the seat of the gastric lesion. In pyloric obstruction there is hypo-phosphaturia from inanition. The form of diminution of phosphates not due to inanition is of much clinical importance. When it occurs in the course of an ulcer of the stomach, it heralds the termination of the period of phagedæna. When the ulcer is about to heal there is hypo-phosphaturia with increased and increasing discharge of chlorides in the urine. When the work of cicatrisation is proceeding regularly the "chloruria" rapidly returns to the normal, and the phosphaturia also, but more slowly. Hypo-chloruria denotes advancing ulceration; hypo-phosphaturia indicates the reparative tendency. In the progress of ulcer of the stomach there is, then, a correlation between the chloruria and the phosphaturia. The chloruria sinks to a low level in cases of imminent suppuration; it rises when suppuration is established, and approaches the normal notwithstanding the persistence of suppuration. Phosphaturia is increased in cases of commencing suppuration, is lowered as soon as reparation begins, and returns to the normal in cases which heal properly. The retention of phosphates, leading to hypo-phosphaturia, characterises a favourable condition of the system, tending to heal the ulcer.

THE ETIOLOGY OF SCARLET FEVER.

IN his last annual report on the health of the borough of Maidstone, Mr. M. A. Adams, the medical officer of health, draws attention to an outbreak of scarlet fever, attacking thirty individuals and causing two deaths, which was clearly due to the consumption of a special milk-supply, but in which it was impossible to connect the milk with any infection of scarlet fever. The outbreak, like others of the same description, was a mild one; and Mr. Adams, having conferred with Mr. Power, of the Local Government Board, on the subject, refers to the views which have been expressed by the latter observer, which are to the effect that a disorder is liable to occur in cows which is able to affect the milk yielded by them so as to produce a disease in persons consuming the milk of the nature of and indistinguishable from ordinary scarlet fever. In this case nothing is stated as to the health of the cows, and we have no facts bearing upon the view in question, except the one showing that the source of scarlet fever infection was not detected. There have, however, been a certain number of scarlet fever outbreaks in connexion with the use of a particular milk which have baffled all who have sought to detect any source of infection coming from a previous case of scarlet fever, and all the outbreaks have certain characteristics in common, such as small mortality. Much more experience is needed before any decided opinion can be expressed on the subject; but, in the meantime, the Maidstone case, investigated as it has been by two skilled observers, may be added to the list of these outbreaks which have some bearing on the question of the transmissibility of disease from the lower animals to the human subject.

LONDON CABS.

IT is no less unaccountable than it is disgraceful that this great city, whose vast population is ever on the move in pursuit of business or pleasure, should still be unprovided with a decent four-wheeled public carriage. The name of the inventor of the hansom cab will probably live when far greater men are forgotten; it is fortunate for the designer of the "four-wheeler" that his is not known, or it, too, might go down to posterity—but with the reverse of blessings. The improvement in the hansom has of late years been notable, and there is now little to be desired with regard to this very convenient cab, which, however, is in our opinion mainly adapted for use in the warmer months, and is not suited to the requirements of all. The chief objection to the ordinary hansom lies in its imperfections as a closed carriage. The front window, when shut, generally either fits too loosely, and so admits the rain, or by fitting too tightly excludes the air. Even when some attempt at ventilation is made in it, the space in which the "fare" (or worse, "fares") sits is so limited as to cause an unpleasant "stuffiness"; while to a timid person the situation must be trying, and certainly the prospect of the possibility of a collision or an upset while thus "cabined, cribbed, and confined" is far from pleasant. In wet weather, too, the cushions of the seats are very liable to become damp. We are aware that one or two faint-hearted attempts have been made to provide London with improved four-wheeled hackney carriages, but nothing has ever come of them. Why it is difficult to say. The large provincial towns and popular sea-side resorts are not satisfied with such

Digitized by Google

ramshackle accommodation. London alone seems content. There is no doubt that a comfortable four-wheeled cab would be appreciated and employed by many to whom a closed carriage is a consideration in fine cold as well as in wet weather. It would certainly soon supersede the present objectionable "growler" and be patronised by many who now use the hansom. Mr. Forder and others have achieved great things for the comfort of the public by improving the hansom. It is high time they turned their attention to the "four-wheeler."

KNEE-JERK IN DIABETES.

THE introduction of one new condition into any existing arrangement cannot take place without producing more than one alteration. The phenomenon of the knee-jerk which may practically be said to have been introduced into the sphere of clinical medicine during the past decade bears testimony to the above generalisation. The investigation of the condition of the knee-jerk may seem to some medical men a somewhat novel application of a reflex action. M. Bouchard made a distinct impression by his paper on the subject at the French Association for the Advancement of Science recently held at Blois. The presence or absence of the knee phenomenon in diabetes mellitus is said to possess much importance both from a prognostic and diagnostic point of view. Forty-seven cases observed during the last three years by M. Bouchard were found to have the patellar tendon reflex, and of these cases only two died, or about 4 per cent. Nineteen cases were collected in which the knee-jerk was absent, and of these six were fatal, or about 33 per cent.; the mortality in the latter group may have been still greater, since some of the number were lost sight of. The members of the second category also had a cachectic aspect. M. Bouchard believes that the disappearance of the knee phenomenon in the course of diabetes indicates the entry into a grave and perilous state. It is perhaps lending too much value to the knee-jerk to say that the absence of it has given the cue to the diagnosis of diabetic coma; a statement to this effect may be found in the report from which we abstract our information on M. Bouchard's paper. An infant was found comatose with dry cracked lips and absolutely afebrile; none of its antecedents could be ascertained. The knee-jerk was absent and the coma resembled that met with in cases of intoxication, and of uræmic or diabetic toxæmia. There was the odour of acetone in the breath; some balano-posthitis and intense thirst. A washing from the child's underlinen reduced Fehling's solution. M. Bouchard thinks it necessary to state that the absence of the "tendon reflex" does not favour the nervous theory of diabetes.

CREMATION AT ILFORD.

AT a late meeting of the Commissioners of Sewers for the City of London at the Guildhall, an interesting discussion took place on the benefit or otherwise to be derived from the practice of cremation, and on the need of erecting a crematorium in Ilford Cemetery. On the part of the Sanitary Committee, it was proposed that the latter project be postponed until the whole subject had received Parliamentary sanction and regulation. An amendment to this motion advised that the Committee be asked to reconsider their proposal. After an animated debate the amendment was carried by twenty-six votes to sixteen. The supporters of the amendment based their action on the following considerations. That cremation afforded the most perfect sanitary method of disposing of the dead, that it did not offend religious principle, that it need not imply illegality, and that radical change was called for in the present system of burial. They further asserted that all science was on their side, and that since the law was not compromised regulation by Government was uncalled for. By the other party the practice was condemned as barbarous, too costly for general adoption, and unnecessary, inasmuch as it had not been asked for on behalf of any inhabitant who had recently died in London, while experience had proved that the earth in every quarter of the globe was still much more than able to perform in a satisfactory manner the ultimate object of the crematorium, which was therefore a superfluity, as it was on several grounds a public nuisance. The strongest points in the case brought forward by the cremationists are the unquestionable statement that burial reform is necessary, and the moderation of their request that the opportunity of burning their dead may be afforded to such of the public as may desire it. It cannot of course be expected that the older custom of interment should ever be completely superseded by the method of immediate combustion, and it seems very doubtful whether the comparative value of the latter can ever be so clearly proved as even to lessen materially the proportion of earth burials. The practical utility of cremation therefore is not very evident. Another statement which was made on its behalf at the recent meeting should not pass unchallenged—namely, that it had the support of all science. No party argument was ever more unfounded. It is true that decomposition in the earth is a slower process, and that it has not in all cases been successfully carried out; yet it must not be forgotten that its failures have been due entirely to the meddling mismanagement of human sentiment which buries the dead to preserve them in a putrid state, or to careless misplacement, or overcrowding of cemeteries, for which there is not even a sentimental excuse. Let the earth have its dead, and be allowed to do its work on them, and the process of decomposition of man, as of innumerable lower animals, will be, though gradual, completely successful, and wholesome to the earth itself, its atmosphere, its vegetable life, and to the inhabitants which people its surface. The highest point to which cremation can hope to attain in the national economy is, in our opinion, that of a permitted practice, but before this can happen a special guarantee is required that it may not be used to destroy the evidence of murder by poison.

SUCCESSFUL RESECTION OF THE HEAD OF THE HUMERUS FOR ANKYLOSIS.

PROFESSOR ALBANESE reports in the *Archivio di Ortopedia* for April an operation for ankylosis of the shoulder, performed in the surgical clinique of Palermo, in the presence of Professor Tommasi-Crudeli. The patient, Maria B——, aged twenty-one, had during the preceding twelve months suffered pain in the right shoulder-joint, which gradually became immovable. The appearance on admission, as shown in an accompanying illustration, suggested downward dislocation of the head of the humerus. The acromion was prominent and the deltoid flattened. The patient could not touch her head with the right hand, and the corresponding olecranon could not be brought nearer than eight inches from the chest wall. The patient being under chloroform, Professor Albanese made an L-shaped incision, three inches and a half in extent, along the spine of the right scapula into the shoulder-joint. The sides of the wound being held open with strong hooks, the head of the humerus was severed by two blows with the chisel on a level with the anatomical neck. The surgical neck, dislocated outwards, was rounded off with gouge and file, so as to fit in a hollow made with a spoon, in the head of the humerus, which was adherent in the glenoid cavity. A drainage-tube was introduced, and the wound closed with interrupted sutures. An antiseptic dressing was applied according to Listerian precepts. Recovery was rapid. The temperature remained normal throughout, the wound was

Digitized by Google

healed within a fortnight, and the patient discharged at the end of a month, with perfect symmetry of the two shoulders. Two months after the operation the patient could bring the elbow to the side, move the arm in all directions, and dress her own hair.

SUICIDE FROM INSANITY.

THERE have been many suicides of late in which no sort of doubt can exist as to the insanity of the self-murderers. In the majority of these lamentable cases there has been neglect on the part of friends, or there has been procrastination as to the adoption of measures of safety. The real cause of this evil is the obstacle which the law throws in the way of prompt treatment by confounding matters which are totally distinct—namely, medical care and legal disfranchisement. There will always be delay and reluctance both on the part of friends and patients hovering on the borderland between mental health and insanity so long as certifying precedes treatment. What the emergency demands and requires is perfect freedom as to treatment; the privilege which is now stoutly denied to the subject of conscious mind worry and weakness of placing himself or herself voluntarily under treatment, as a sick man seeks rest and medical care for his bodily ailments in a hospital, public or private. Why should this obvious recourse be closed against the subject of mental disorder or disease? We have no hesitation in asserting that in nine instances out of ten the patient is self-conscious of the malady before it becomes apparent to those around him. On this point we are absolutely certain, and it would not be difficult to prove this position by facts. If asylums were *hospitals*, and nothing more, there would be comparatively few suicides, and the proportion of admissions to recoveries would be sensibly reduced.

PROGRESSIVE MORTALITY OF MEASLES IN PARIS.

THE first article in the *Archives Générales de Médecine* for this month is one of exceptional interest to sanitarians. Its author is Professor Auguste Ollivier, physician to the Hospital for Sick Children in Paris, and his observations are embodied in a report to the Prefect of Police, who is *ex officio* president of the Council of Public Hygiene for the department of the Seine. Without attempting a literal translation of the article, its salient facts and conclusions may be thus summarised. That measles is a necessary and not serious eruptive fever is a popular fallacy. Of 57,024 deaths which occurred in Paris in 1883, 1058 were due to measles, equivalent to 18·55 per 1000, or nearly 2 per cent. In the same year measles came immediately after diphtheria (1951 deaths), amongst diseases universally admitted to be contagious. Whereas diphtheria is nearly equally fatal at all ages, the gravity of measles decreases as years advance. In 1000 deaths from measles, only 8·57 were in persons above fifteen years of age; below that, the number was no less than 991·43. Hence the practical precept, to protect infants from one of the most serious diseases which can attack them. The longer the attack can be deferred, so much less will be its seriousness. Of late years the ravages of measles in Paris have been steadily on the increase. In 1865 it was the cause of 343 deaths, in 1869 of 540, in 1873 of 561, in 1879 of 917, and in 1883 of 1058. This regular gradation might be supposed to be attributable to a corresponding increase of population, but it is not so. Reckoning the proportion of deaths from measles in 100,000 inhabitants, it is proved that in 1865 that ratio was 18·8, whereas in 1883 it was 47·1. Consequently the present mortality from measles in the French capital is nearly three times as great as it was twenty years ago. A single word suffices to explain the nature and the spread of the disease: contagion. Infant nurseries (*crèches*), schools, dispensaries, and the out-patient departments of hospitals, are the great centres for the propagation and diffusion of the disease. The increase in the number of cases of measles in Paris admits of explanation by the growth of the scholastic and hospital population, and by the insufficiency of means for isolation. The medical inspection of all schools is a matter of the first importance, so that the earliest symptoms of the affection may be detected at once. In hospitals for sick children, applicants for relief should be inspected in a reception hall by a specially appointed medical officer, by whom cases may be at once classified, and those presumably contagious isolated immediately and effectively.

CHOLERA IN INDIA.

THE epidemic wave of cholera which swept down from Bengal and invaded the Madras Presidency in 1881 has lingered somewhat longer than usual, but is now showing signs of dying out. The rich Collectorate of Tanjore has suffered very severely, and its persistence in this territory led the Government lately to send down their sanitary commissioner to investigate the causes of its continuance. Dr. Farnell is of opinion that the severity and persistence of cholera in Tanjore are owing to the peculiar water-supply of the district, which is faulty in the extreme. The people of even the large towns, and it is invariably so in the villages, are dependent upon tanks for their drinking water. These tanks are defiled in every conceivable manner. People wash their bodies, clothes, and even the clothes taken from people who have died of cholera, in the water, and take home the fluid thus defiled to cook and use for drinking purposes. The sanitary commissioner has recommended that wells should be sunk in all villages, and looked upon as Government wells, rigorously watched and kept from defilement. Then the people should not only be taught, but compelled, to obtain their drinking water from these wells, using the tanks only as bathing and washing places. He points out that where this has been done, notably in Guntur, cholera epidemics, once so frequent, have entirely ceased. These views, which have for some years past been strenuously advocated by the Madras Sanitary Commissioner, are in accordance with Dr. Koch's recent discoveries.

MYSTERIOUS DEATHS AT LAMBETH.

ON Monday, Sept. 22nd, John Warren, a labourer, aged fifty-five, and Martha Warren, his sister, aged sixty-four, were found dead at Webber-street, Waterloo-road. The body of the former was discovered in the sitting position in the watercloset, the door of which was fastened on the inner side by a piece of string. That of the woman was dressed, lying on its back in the bedroom. There was nothing in the external appearances to indicate with certainty how death had occurred in either case, but from the advanced state of decomposition it was clear that the woman had been dead for some time. At the inquest it was shown that although Warren and his sister were impecunious, both food and money were found in the house, a fact which seems to negative the supposition that they had succumbed to starvation. The surgeon who had instructions to conduct a post-mortem examination did not carry them out because he "felt himself too old to perform it." He gave it as his opinion that the oozing of blood from the mouth of the woman was due to apoplexy, to which he ascribed the death, and that from the hands of the man being open he thought he had died from syncope. Upon this evidence the coroner put it to the jury whether they thought it advisable for a post-mortem examination to be held. They considered it was not, and accordingly returned a verdict

Digitized by Google

of "Death from natural causes." The finding of the jury was "in accordance with the medical evidence"; still for all that, we unhesitatingly affirm that it was not only advisable, but necessary, that a searching investigation should be made. Here were the bodies of two adults who had evidently died at or about the same time, a coincidence strange in itself; there was no proof that either had met with any violence, or suffered from disease likely to be suddenly fatal. The interpretation of the facts made by the medical man may or may not have been correct, but to our minds the oozing of blood from the mouth was far more likely to have been the result of cadaveric putrefaction than of apoplectic effusion. Again, even had the man died from syncope, the question still remains, What was the cause of the syncope? Our experience leads us to the conclusion that the position of the hands is of little value in itself. The absence of the smell of alcohol or other poison is negative testimony of very small moment, seeing that death had taken place some considerable time prior to the finding of the bodies. If such cases as the one just related are allowed to pass into the category of "death's mysteries" without a reasonable examination into the circumstances, crime will not diminish for lack of encouragement.

ACTION TO RECOVER MEDICAL CHARGES AT POOLE.

The Bournemouth Visitors' Directory contains the report of an action by Mr. Herbert A. Lawton, of Poole, to recover £21 from Mr. Henry Mitchelson, bank clerk, of London, for attendance on Mrs. Mitchelson for seven months. The case was one of renal disease, with affection and ultimate loss of vision, which all medical men know too well to be not uncommon. The husband of the patient on two occasions, about Christmas and Easter respectively, expressed himself completely satisfied with the treatment. In fact all seemed satisfactory till the bill was sent in. Thereafter dissatisfaction was expressed not only with the bill but with the treatment. All sorts of charges were made against the medical man for which no kind of justification could be made out. The judge was assisted by Mr. Wyke-Smith, acting as an assessor. He repeatedly advised the defendant—whose case was conducted by the patient herself in the unavoidable absence of the solicitor, who, by the way, was severely reflected on by the judge, for writing such letters as he had done to the plaintiff—to withdraw the accusations against the doctor and accept the account. The reasonableness of the charges, amounting to about 3*s.* 6*d.* a visit, was, he said, incontestable. But the lady would not take the advice kindly and repeatedly proffered to her, and the judge gave a verdict for £21 and costs.

CRÈCHES AND EPIDEMICS IN FRANCE.

As disinfection in cases of contagious fevers &c. is not enforced in France, it is not surprising that institutions such as a crèche are accused of spreading disease. Undoubtedly epidemics have broken out in crèches, but it is a question whether the children would not have been exposed to greater dangers if left at home. Nevertheless a certain amount of feeling against the crèche, as an institution, has been manifested on the other side of the Channel, and in self-defence the Société Française des Crèches commissioned Dr. René Blache to seize the earliest opportunity of pleading in favour of the institutions it is their mission to promote. Dr. René Blache consequently delivered a lengthy statement on the subject before the International Congress of Hygiene, pointing out that the crèche only took the children during work hours. Twice a day the mothers should come to feed their children; but, unfortunately, they did not always observe this rule. In certain trades, indeed, this was almost impossible, and it was therefore necessary to give the children a mixed diet, and the result was consequently unsatisfactory. The epidemic question had been discussed at Amsterdam, and in many great centres. A special report was drawn up on the subject for the Paris prefect of police, and several crèches had to be closed in consequence of diphtheria. But Dr. René Blache contended that wherever children congregated together there was danger of contagion. A crowded street was more dangerous than a crèche, for in the latter institution the strictest watch was kept, and the first slightly suspicious symptom sufficed to ensure the exclusion of the child. An epidemic generally came from the street to the crèche, and its spread was stopped by the closing of the institution. The crèche was a moral school as well as a school of health: it taught the mothers that it was their duty to nurse their children, and helped them to obtain indulgences and facilities from their employers. The crèche also combated the ignorant superstitions with respect to the nursing of children and taught the gospel of cleanliness, thus reducing the probabilities of epidemics. In a word, so long as mothers are obliged to work and abandon their children during the day, the crèche is a good institution. But the question arises whether the existence of a crèche does not encourage mothers to abandon their domestic duties and seek for employment. This must of necessity tend to flood the labour market, and reduce the wages of the men as well as of the women who were previously at work. With a reduction of wages come a lowering of diet and the overcrowding of tenements, followed by a general falling off in the health of the majority—that is, of the industrial population.

"A GIGANTIC CESSPOOL."

SUCH is the very startling description of Windermere Lake given by Lieut.-Colonel Sandys. In answer, it is not denied that sewage enters the lake, but it is pointed out that its effects are unappreciable, as the greater portion is passed through tanks which retain the solid matter. It is stated that 150,000,000 gallons of water pass through the lake daily, and that Windermere virtually renews itself once in eight months. Lieut.-Colonel Sandys, who is said to be the owner of a neighbouring lake, has been requested to justify in writing his charges. Mr. S. J. Smith, the Local Government Board inspector, met a number of residents at Bowness on Tuesday, and strong representations were made to him by those who deny the statement concerning the lake. After the interview the inspector visited Windermere, and will, it is understood, report to the Local Government Board on the subject. The allegation is a serious one, and demands prompt investigation.

MOSQUITOES AND YELLOW FEVER.

THE following propositions, which give in a condensed form the chief conclusions of Dr. Carlos Finlay's work on Yellow Fever, deserve consideration. Ordinary yellow fever is inoculable by means of the bite of the mosquito (Culex mosquito) on the third, fourth, fifth, and sixth days of its natural evolution. The disease cannot be transmitted by the agency of the insect before the third day or after the sixth, no matter what the severity of the disease. The period of inoculation of this experimental inoculation varies as widely as that of natural yellow fever. The duration and severity of the fever produced by inoculation by the mosquito appeared to be proportional to the number of the bites, and presumably to the quantity of matter contained in the insect's fang. The inoculation with one or two bites of the insect has never been followed by phenomena other than those usually met with in benign yellow fever. The results obtained up to the present lend hope to the suggestion that the inoculation

Digitized by Google

by means of one or two *piqûres* of the mosquito may confer immunity from the severe forms of the disease to those who have to dwell in its midst. The inoculability of the disease by the agency above indicated points to the value of guarding patients suffering from yellow fever against the bites of mosquitoes in order to prevent the spread of the malady.

AN IMPUDENT DEFENCE OF CANNIBALISM.

THE *Catholic Times and Catholic Opinion*, in an extenuating notice of the act of the captain and sailors of the *Mignonette* in killing the boy to keep themselves alive, uses a strange argument, which we call upon our contemporary either to withdraw or to justify. He alleges with much assurance that doctors administer drugs to persons dying of painful diseases, which will not only allay pain but will "also surely hasten death." We deny this. Pain such as he contemplates is a deadly thing. There are, mercifully, remedies which relieve such pain. But the effect of such remedies is rather to prolong than to shorten life by destroying the pain which kills—and kills cruelly. Our contemporary must find some better argument on which to base a justification of two or three men killing a weak boy. We are quite prepared to recognise extenuating circumstances; but it will be a bad day for the reputation of British sailors if such acts only excite ingenious and false arguments in defence. Life at sea—the life of the young and the weak—needs to be regarded with exceptional sacredness.

THE IMPORTATION OF RAGS.

THE orders of the Local Government Board prohibiting, except under certain conditions, the importation of rags from France and Italy until Oct. 1st, have been further extended for the period of one month, and Spain has been added to the list. It seems rather a feeble proceeding to issue these orders for so short a period, and one which certainly tends to induce shippers to hold their freights in the hope of a free entry. In this sense it is unfair to them, and likely to cause the very mischief it seeks to avoid. The only exception is where the sanitary authority or their medical officer is satisfied that the rags have been shipped from some part of the country where no case of cholera has occurred. Inasmuch as rags are collected in very small quantities over large tracts of territory, it seems very difficult to understand how anyone can be satisfied as to the place of collection unless a responsible certificate accompany every piece of rag, and we trust that medical officers will seriously consider the possibility of admitting infected material into the country.

POLICE SURGEONS' FEES.

WHILST hearing a charge of assault at the West Ham Police-court on September 21st, the magistrate, Mr. Phillips, made an important announcement as regards the payment of fees charged for attendance by the district surgeon. It appears that attached to the charge sheet was what a court official described as "just a form" provided by the Police Commissioners, but without any statement or certificate from the surgeon as to the nature of the case he was called to see. The magistrate intimated that in future he should disallow the fee unless there was evidence that the doctor had done something to earn it. We cannot justly complain of this innovation, because it is only fair to the accused that the surgeon should either attend the court and testify to his observations and opinion, or record the same in writing. Moreover, we hold that if a person is suffering from the effects of an injury of such gravity as to require medical aid, the administration of justice demands all the assistance that skilled professional knowledge can afford.

PLEASURE STEAM YACHTING IN THE MEDITERRANEAN.

MORE than one medical correspondent has sent us [illegible] from which it appears that the Pleasure Steam Yacht [illegible] pany offers "the usual fee of five guineas" to medical [illegible] fares taken through their recommendation. This offer [illegible] discreditable to the Company, and is certainly not [illegible] to the medical profession. Medical men are suppose[d] paid for their advice by those who consult them. [illegible] should be paid by a commercial company for advice [illegible] able to the company would not increase the confidence [illegible] public or of their patients. We trust we shall hear [illegible] of such a system of touting. We have, of course, not [illegible] say against such a pleasant adventure as an escape [illegible] winter climate in a large well-found pleasure yacht, [illegible] duly qualified medical man on board.

COCAIN AS A LOCAL ANÆSTHETIC.

DR. BEER of Vienna has favoured us with a [illegible] cation from which we extract the following note. [illegible] recently Dr. Koller, of the Vienna General Hospital, [illegible] covered in cocain a valuable agent for the production [illegible] anæsthesia. He found that the introduction of [illegible] three drops of a 2 per cent. watery solution of cocain [illegible] the corneal chamber rendered both the conjunctiva [illegible] cornea completely insensitive, so that, for instance, [illegible] cornea could be partially gouged without exciting any [illegible] action or sense of pain. The same fact was demonstrated [illegible] by Drs. Brettauer and Becker at the recent Ophthalmic [illegible] Congress. Koller in his first report mentioned the [illegible] ment of the same agent in the production of anæsthesia [illegible] the larynx.

THE HOSPITAL FÊTE.

ON Wednesday the Lord Mayor received the following letter from the Duke of Buckingham and Chandos:—

"International Health Exhibition,
South Kensington, S.W., [illegible]

"MY DEAR LORD MAYOR,—I am glad to be able to [illegible] a further sum of £500 arising from the Hospital Fête. It is possible that a further small amount may still be found for the Hospital Sunday Fund after the final expenses have been paid.—Yours very truly, BUCKINGHAM AND CHANDOS, Chairman, Executive Council."

A meeting of the Council of the Fund is, we understand, fixed for the 10th inst., to distribute the money realised from the fête.

ACETONURIA AFTER POISONING BY SULPHURIC ACID.

ACCORDING to the *Birmingham Medical Review*, Hoppe-Seyler has recently described a case of poisoning with concentrated sulphuric acid, in which, six days after the accident, an acetone-forming substance appeared in the urine, which smelt of acetone and gave a red colour with ferric chloride. The excretion of this chemical body [illegible] in diminishing quantities for four days, during which the patient took scarcely any food. The substance disappeared from the urine after the ingestion of food by the stomach.

THE BOARDING OUT OF PAUPER CHILDREN.

THE Holborn guardians have almost unanimously resolved to call back the children they had put out to board. The resolution was consequent on a discussion raised by the clerk's report of the state of one of the children who had been sent back in a very dirty and neglected condition. The Rev. N. Davies, in whose resolution the children were sent, seconded the motion. It is not remarkable that the

Digitized by Google

guardians should have felt something like indignation at this case, nor that they should have acted as they did. But it would have been more satisfactory to have had a complete report of the state of all the other children boarded out. Everything in the boarding-out system depends on the faithfulness of those who undertake to watch the children; and in this case they seem to have neglected their duty. The case only came to light accidentally, as the child proved unmanageable by its foster parents and had to be sent back. The Holborn Union guardians have spent large sums on their schools at Mitcham, where the children are taught trades, and so are more averse to the boarding-out system.

THE report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of August, states that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies again exhibited the comparatively small proportion of organic matter which has characterised the samples collected since April last. With the exception of the Lambeth Company's water, which was slightly turbid, all the samples were clear and bright. The water drawn from the Lea was of the same quality as in the previous month, and contained less organic matter than any of the Thames waters.

MR. WILLIAM BATES, B.A., M.R.C.S., Classical Professor at Queen's College, Birmingham, and Surgeon to the Borough Hospital, died somewhat suddenly a few days since. Mr. Bates' literary attainments were well known, and his loss will be greatly felt in other circles than the medical, in which he was held in high esteem.

DURING October Mr. Watson Cheyne will give three special demonstrations on Bacteria at the Biological Laboratory, Health Exhibition. On Tuesday, Oct. 7th, at 4 P.M.: "Methods of Preparing and Sterilising Cultivating Media." Tuesday, Oct. 14th, at 4 P.M.: "Methods of Cultivating Bacteria." Tuesday, Oct. 21st, at 3.30 P.M.: "Methods of Demonstrating Bacteria (Staining &c.)."

DR. EDWARD T. WILSON has issued a card entitled "Disinfectants, and How to Use Them," which is calculated to be extremely useful, especially to householders and managers of public institutions. A large amount of information is compressed into a small space, and is arranged in a form convenient for ready reference.

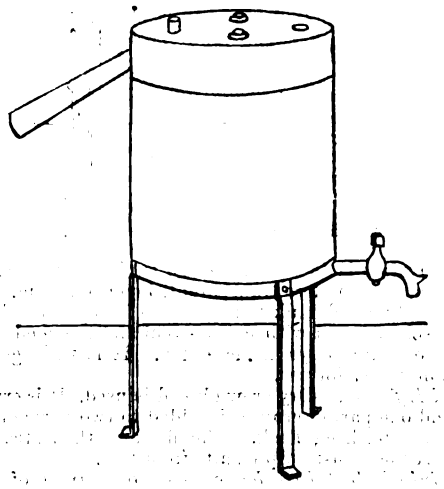
MR. FREDERICK TREVES, F.R.C.S., has been elected surgeon to the London Hospital, in the place of Mr. James Adams, who has resigned on account of continued ill-health.

SMALL-POX in a virulent form is stated to have broken out at Trieste.

PLUMBING.—On the 26th ult., a representative meeting of gentlemen interested in the art and trade of plumbing was held at the Guildhall, to consider the desirability of action being taken by which the status of the trade might be advanced, and the interest of the the public protected from evil arising from bad work and bad workmen. Resolutions were passed requesting the Plumbers' Company to communicate with the National Health Society, the Sanitary Institute, and otherwise to arrange for the conference of metropolitan and provincial plumbers to be held at the Health Exhibition from Oct. 15th to 20th.

THE

BIOLOGICAL LABORATORY AT THE HEALTH EXHIBITION.



No. V.

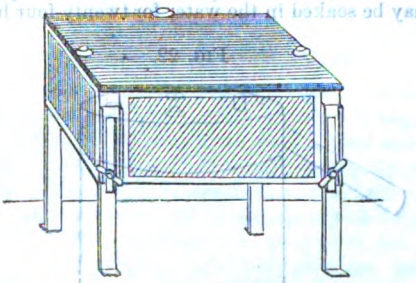
CULTIVATING MEDIA.

Potatoes are very good material for the cultivation of many forms of bacteria. In preparing them they are first thoroughly scrubbed with a nail brush, removing the dirt, but leaving the skin whole. They are then soaked for ten minutes in a solution of corrosive sublimate (corrosive sublimate 1 part, water 1000 parts), and after this they are steamed for half an hour. When cool they are cut in half with a knife heated in a flame, and the halves laid with the cut surface upwards in one of the dishes above described. The dish has been previously sterilised by being rinsed out first with the corrosive sublimate solution, and then with methylated spirit. Round the interior of the dish blotting-paper soaked in corrosive sublimate solution is arranged, and this maintains a moist atmosphere. When they are quite cool the potatoes are inoculated by means of the inoculating needle, which is dipped in some growth of the organism to be cultivated, and then drawn over the cut surface.

Meat Infusion.—This is made from meat which is as far as possible free from fat. To make one litre of infusion one pound of meat is taken, and chopped up into mincemeat. This may then be set to simmer in a litre of water for one hour, after which the solid parts are separated by straining; or it may be soaked in the water for twenty-four hours in an

FIG. 22.

Apparatus for sterilising blood serum.



ice-safe. At the end of this time the liquid part is poured off and the meat is pressed so as to extract all the juice from it, and this is added to the rest of the liquid. The remaining part of the process is the same in either case. If a neutral solution is required, the liquid is neutralised with sodium carbonate and sodium phosphate (Na_2PO_4), the latter salt being used to complete the process. When a peptonised solution is needed the peptone is stirred in and dissolved at this stage. The liquid is then boiled to coagulate the albumen, strained and filtered, and then steamed for half an hour. After this it is filtered and steamed again, and if it is not quite clear the process is repeated. When clear the liquid is introduced into one of the flasks above described, and then steamed for three days in succession for half an hour each time. This is Tyndall's method of sterilising a fluid. Before it is first strained the infusion contains micro-organisms, both spores and active forms. The latter are killed by the first steaming, and during the first interval the spores have time to develop into active forms, which are killed at the second steaming. The third steaming kills any which may not have developed at the first interval. Infusions so treated

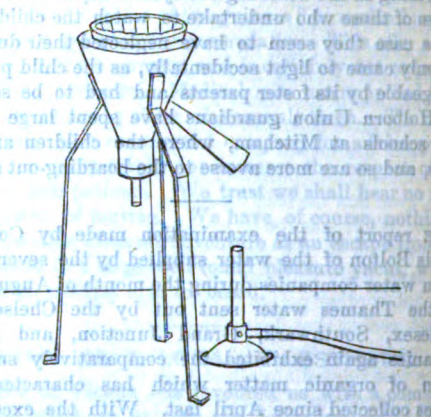
Digitized by Google

may be kept, in well closed vessels, clear and sweet for an indefinite length of time.

Coagulated Blood Serum.—This may be used for cultivation at the body temperature. Sheep's blood is the best to use. Immediately after it is taken from the body it is poured into tall glass vessels where it is allowed to coagulate. The froth is carefully removed from the top of the liquid, and any blood which there may be on the upper, empty part of the vessel is wiped away. It is best to keep the vessel in an ice safe while the serum is separating. After thirty-six hours the serum is carefully drawn off by means of a syphon and received into a flask. From this it is transferred to sterilised test tubes. The serum is sterilised in the apparatus represented in Fig. 22. It consists of a cylindrical box with double sides, floor, and lid which contain water. The lid has a process by which it may be heated separately from the rest of the box. There is a central pillar in the interior and four vertical partitions passing from it to the sides. These are for the purpose of supporting a number of test tubes in a vertical position. The test tubes containing the serum are placed in here and sterilised by being heated for six days in succession, to a temperature of 58° C. for one hour a day. In order to coagulate the blood serum the tubes are transferred to another box, represented in Fig. 23. This is a wide shallow box which also has double sides and floor, and a glass top covered with a layer of felt. The two front legs move in grooves in the side, and may be clamped in any position. By this means the floor of the box may be made to slope. The test tubes are laid on the sloping floor of this box and heated to a temperature of 65° C. until the serum is coagulated. The object of placing the tubes in an

FIG. 23.

Apparatus for coagulating blood serum.



oblique position is to obtain a large surface for inoculation, and a thin, and so more transparent, layer of serum.

Milk.—Skimmed milk is introduced into previously sterilised vessels plugged with cotton-wool and steamed for half an hour on three days in succession. It is then generally sterile and ready for use.

Bread Infusion.—Dry brown bread is used. It is crumbled finely and one part of crumbs is added to two parts of water, in a small sterilised flask. The flask is then steamed as usual. A fine moist pulp results from this.

Gelatinised Meat Infusion consists of extract of 1 lb. of lean meat; gelatine, 50 to 100 grammes (or Japanese isinglass, 10 to 20 grammes); peptone, 30 grammes; sodium chloride, 5 grammes; water, 1 litre. The Japanese isinglass is used instead of gelatine in cases where it is necessary to obtain a material which will remain solid at the temperature of the body—the gelatine mixture becomes liquid at that temperature. The extract of meat is made in the same way as for the simple meat infusion, except that only half a litre of water is employed. The other half litre is used to soak the gelatine or Japanese isinglass. The latter should soak for twenty-four hours before the infusion is to be made. The gelatine (or Japanese isinglass) is added, with the water in which it has soaked, and dissolved in the hot extract of meat, and the peptone and salt are put in. The solution is neutralised as above described. In order to obtain a clear solution, the whites of two eggs are beaten up with some of the liquid, and then added to the mixture slowly, while it is stirred. On boiling, the albumen of the eggs rises to the surface, carrying with it the solid particles, and leaving a nearly clear fluid. This fluid is now poured off, strained, and filtered. In order to keep the liquid warm while it is being filtered, the apparatus represented in Fig. 24 is employed. It consists of a funnel-shaped water-bath, with a side process which projects over a Bunsen's burner. It is closed below by a caoutchouc stopper. The glass funnel used in filtering is placed in this bath, with its stem piercing

FIG. 24.

Apparatus for filtering gelatinised meat infusion.

the stopper. The liquid, when it is filtered, is put into one of the flasks above-described, and thence it is transferred to test tubes, which have been purified by heat. The liquid is then sterilised by Tyndall's process.

LUNACY IN SCOTLAND.

THE Commissioners in Lunacy for Scotland have just issued their twenty-sixth annual report, being that for the year 1883. It shows that on Jan. 1st, 1884, there were 10,739 lunatics under their official cognisance. Of these, 5017 were males and 5722 females. For every 100,000 of the population of Scotland there are 273 lunatics, or a proportion of 1 lunatic in every 366 of the population. The maintenance in 8985 cases was provided by parochial rates, in 1701 cases from private sources, and in 53 cases at the expense of the State. The average daily cost of maintenance of pauper patients is 1*s.* 4*d.* The substance of the report itself may fitly be distributed under three heads:—(1) The insane in asylums and other public establishments; (2) the insane in private dwellings; and (3) the use of the certificate of emergency.

1. With regard to the insane in public establishments, we find that the admissions in 1883 were greater than during the preceding year by 47 among private and by 170 among pauper patients. The mean recoveries per cent. of admissions into asylums and poor-houses was 28. The rate of mortality per cent. of the number resident in different classes of establishments for the year 1883 was, in royal and district asylums, 8·2; in private asylums, 6·4; in parochial asylums, 10·0; and in lunatic wards of poor-houses, 5·2. During the year 167 patients were discharged on probation; and we are informed that of the total number (2647) of patients discharged on probation since 1862, 483 were replaced in the asylums from which they had been removed before the expiration of the period of probation. There were 318 escapes in the year. With the exception of 38 they were all brought back before the legal period for their recapture had expired, and, in the great majority of cases, before they had been away twenty-four hours. Of the 120 accidents reported as having taken place during the year, 17 ended fatally. In 11 of these cases the death was the result of the patients' own acts, 9 being regarded as intentional suicides. One of the fatal accidents, we are told, resulted from one patient being assaulted by another. This "accident" was, presumably, a case of murder, or at least of manslaughter, as the surviving patient was placed in the Criminal Lunatic Department of Perth General Prison. In 32 cases the accidents involved fracture of bones or dislocation of joints. A most interesting table is presented of "the progressive history of patients first admitted into

Digitized by Google

establishments in the year 1868." We gather from this that the proportion of recoveries among the 1319 patients admitted in 1868 was during the first two years something like 20 per cent. greater than the proportion of recoveries during the succeeding fourteen years. With regard to the data furnished by the number of deaths, the commissioners say: "It may safely be concluded from them that the annual death-rate among patients who have been less than four years inmates of asylums is from about 12 to 25 per cent. of the number resident, and that among those who have been more than four years and less than sixteen years inmates of asylums the annual death-rate is only an average of 5 per cent. of the number resident." This statement would attain a truly scientific interest if it were carried a step further, so as to show, upon similar lines, the mortality due to diseases of the brain and nervous system. The pathological instructiveness of a case of insanity is never completed if the patient dies of heart disease, for instance, or of peritonitis. But if the cause of death can be traced back as a progressive development, in time, of the physical condition of which the insanity is the outcome—i.e., if the insanity and then the death are traceable to the same *origo mali*—how instructive, in its unity and consecutiveness, does the pathological history become!

The commissioners speak very favourably of the generally efficient management and administration of the lunatic asylums in Scotland.

2. Overcrowding is largely prevented by the Scottish system of providing for the insane in private dwellings. On January 1st, 1884, the number thus provided for with the sanction of the Board, was made up of 128 private and 1811 pauper lunatics. This department is more especially the province of the two deputy commissioners, whose reports, given in the appendix, are thoroughly well worth perusal and attention. The experience of the commissioners themselves is entirely in favour of this domestic method of dealing with the insane, and they "have no doubt that in every case prolonged detention in an asylum ought, if possible, to be avoided, unless the interests of the patient or of the public unmistakably require it." We quite agree with this opinion, which indeed, is of the nature of a truism. The difficulty lies in getting the interests of the patients properly looked after, at low rates of remuneration, outside an asylum. If this difficulty of suitable guardianship could be met—and the Scottish practice shows that, so far at least, it can be met—there would be no lack of patients, in these days of cumulative overcrowding. But such patients should be quiet and harmless, for we do not hold with Deputy Commissioner Lawson, when he advocates the "reclamation" of "troublesome ones" in private dwellings. Here the public interests come to be at stake. The interests of the public cannot be served by the presence in their midst of a woman, who, whatever her other virtues may have been, was "restless and bouncing like a deer of the forest," whose affectionateness was "somewhat florid and fawning," who had been "very depraved in her habits," (however, "no *great* degradation in that respect in her new home"!) and who formed a "mutual attachment" with the children of a neighbouring farmer. The improvement in the condition of this woman (M. McB——) "who now speaks a good deal in a jargon which the guardian readily understands," has been very gratifying to the deputy commissioner, who informs us that he was "much struck with the assiduity of the guardian, and could not help noticing that, though she made no complaint, her strength had been taxed by incessant worry." The interests of the public and of a lunatic like M. McB—— living out of an asylum will seldom be found to run on parallel lines.

3. The use of the "certificate of emergency" is peculiar to the lunacy law of Scotland. The legal position of this certificate is shortly stated thus. It is necessary for the continued detention of a lunatic in an asylum that an order for such detention should be granted by the sheriff, and this order is granted upon a petition being presented to the sheriff accompanied by two certificates by medical men stating that the person is a lunatic and a proper person to be detained under care and treatment; but it is also provided that the superintendent of an asylum may receive and detain "for any period not exceeding three days, and without any order by the sheriff, any person as a lunatic whose case is duly certified to be one of emergency" by one medical man. It is not in practice considered that there must be imminent danger to life to constitute circumstances of emergency. The fact that to wait till an order of the sheriff could be obtained would cause undesirable delay in placing a patient under proper case is regarded as sufficient for this purpose. It consequently happens that in the majority of cases patients sent to asylums are admitted in the first instance on the authority of a certificate of emergency. We have no intention of dwelling on the question of the desirability of such certificates; but one or two points strike us in connexion with them. The "emergency" exception to the general rule of certification appears itself, on no very good grounds, to have taken the place of the rule. "Waiting for the sheriff," who, perchance, has gone for a few days' fishing, seems to constitute the "emergency" upon which the lunatic is, out of the usual course, taken from his home to the wards of an asylum. No doubt there are cases where the notion of "emergency" may legitimately be entertained, but, on the other hand, we hold that, under ordinary circumstances, provision should be made for the usual requirements of the law, in the matter of certificates, being carried out without unreasonable delay. We entirely deprecate any hot haste in having the asylum key turned upon an insane person; and the jealousy of the public eye in England is not likely soon to permit the certificate of one medical man to be the only requisite for the lodgment, even for three days, of an individual, especially a moneyed individual, in a lunatic asylum. The commissioners, however, say:—"A consideration of the whole working of the law, as we have it in Scotland, leads us to view the power of placing a patient in an asylum on the authority of a certificate of emergency with decided approval." Of all the cases so certified during the three years 1880-82, 67 were, for various reasons, discharged before the expiration of the three days during which the certificates authorised detention.

From a social standpoint, we regard this report as of immense importance, dealing as it does, outside the usual asylum statistics and detail, with what may fairly be termed extended experiments (*a*) on the speedy removal to asylums of patients in the acute stage on emergency certificates; and (*b*) on the transfer from asylums to private dwellings of chronic cases of insanity. We gladly welcome original and useful work of this kind.

DINNERS AND CONVERSAZIONES.

THE usual inaugural dinner of the past and present *alumni* of *St. Thomas's Hospital* took place on October 1st, Sir Edwin Saunders being in the chair. Dr. Ord, who was called upon to reply to the toast of "The School," took the opportunity of announcing his early retirement from the office of dean, the duties of which he felt himself no longer able to fulfil in consequence of his increasing engagements. Mr. Le Gros Clark was called upon to make a presentation to Mr. Elliott, who for thirty years has acted as surgeryman to the hospital. He remarked that during that long period Mr. Elliott had not only fulfilled his office to the satisfaction of the staff, but had in many ways contributed to the prosperity of the hospital and of the school. The dinner was a generally admitted success, largely due to the services of the honorary secretaries, Dr. R. P. Smith and Mr. Makins.

The *Westminster Hospital* annual dinner was held at the Holborn Restaurant, and, thanks to the exertions of Dr. Murrell and Mr. Barrow, proved in every way a success, being largely attended by both old and present students. Dr. Potter ably filled the chair, and alluded to a remark of Justice Willes, who had filled a similar post in the afternoon at the distribution of prizes, that the sanitary condition of the nation was the largest question of the present age. The evening was much enlivened by songs from Mr. Black and others, notably by excellent recitations from Mr. Watts Russell and Major Davis.

At the *London Hospital* in the evening of Wednesday, October 1st, the members of the Volunteer Hospital Corps gave a display in uniform before the Lord Mayor, Lady Mayoress, and a numerous assembly. After the distribution of prizes the curtains of the huge marquee, erected for the occasion, were pulled up, and by well-directed limelights the large field in connexion with the hospital was illuminated. A number of supposed wounded and dead were seen lying in all directions. First one, then a second, and finally a third body of the Volunteer Hos-

Digitized by Google

pital Corps appeared on the field with stretchers, haversacks, and water-bottles, and proceeded at once to attend to the wounded. From the field to the dressing stations it was, on account of want of space, but a short distance. In the dressing stations, which also served as field hospitals, the sisters of the Red Cross acted as nurses. Afterwards there was a march past in stretcher detachments, followed by patients on cacolets, litters, and ambulance waggons. The Lord Mayor and Lady Mayoress afterwards visited the dressing station, and inspected the wounded. The students were of the different hospitals belonging to Charing-cross, University, St Bartholomew's, Middlesex, and the London. Surgeon-General Sir Guyer Hunter, K.C.M.G., the Commandant, allotted the directions of the movements to Mr. Cantlie, senior officer of the corps, with Dr. Squire as adjutant, to whom, and to Mr. McLure and Mr. Robertson, the complete success of the parade was due. Members of the London Scottish and Middlesex Artillery acted as patients.

No address was given to the students at *Guy's* during the day, but on October 1st a largely attended conversazione was held, several of the wards being set apart for the reception and entertainment of the visitors, whose number was estimated at 3000. In addition to many interesting microscopical exhibits and displays of surgical and other instruments, all the museums for which the hospital is celebrated were thrown open to the public. The electric light was largely used, and an instrumental concert was given. During an interval, Mr. Lushington, the treasurer, distributed the prizes gained by the students in the Medical School during the past year. Dr. Wilks, senior physician, in moving a vote of thanks to the chairman, stated that the condition of the medical school was prosperous.

The biennial dinner of the old students of *King's College Hospital* was held at Limmer's Hotel on Wednesday, October 1st. Sir William Bowman presided.

THE PROGRESS OF CHOLERA.

CHOLERA still clings with singular tenacity to Italy. In the city of Naples there has been substantial improvement, but the deaths are still from fifty to sixty a day, and the disease has spread somewhat widely over the province of Naples. But improvement in one part of Italy is again associated with extension elsewhere, and English families who have clung to the idea that the Riviera would still be open to them this winter will see with regret the serious outbreak in and about Genoa. Spezia also still remains gravely infected. Taking the entire kingdom, there has been improvement during the past week, but the daily cholera mortality certainly exceeds 200. Rome has again suffered from isolated attacks, which have at once been segregated. This action, and the modern sanitary improvements which have been carried out, have again stood the citizens of Rome in good stead, and have saved them from any extension of infection.

At Marseilles and Toulon fresh cases still occur, and hardly a day passes without one or more deaths. It may be some time yet before these two towns can be regarded as free from infection. Fortunately, there is no further spread of the disease in France.

In Spain the number of infected places does not increase, and no large mortality has occurred in any one town. The provinces of Alicante and Tarragona are, however, still seats of the disease, and much suffering is being experienced by reason of the sanitary cordons which are maintained, and which seriously interfere with trade and with food supplies.

QUARANTINE AND INFECTED PORTS.

Vessels arriving at Constantinople from ports beyond Suez and not subject to quarantine will be admitted to free pratique if they have not embarked passengers during their passage through the canal. On arrivals at Constantinople from Montenegrin ports ten days' quarantine is imposed.

The Danish Government have imposed a quarantine on all arrivals of vessels from any French or Spanish Mediterranean port or any port on the mainland of Italy, on the Gulf of Genoa, or the Sea of Tuscany, on board which any suspicious cases of illness have occurred.

Ships from Spanish ports will, on arrival in Austrian ports, be subjected to ten days' quarantine, provided their voyage has been healthy, and to twenty days' quarantine if any suspicious case of illness has occurred on board.

Vessels arriving at the Gambia from France which have occupied less than twenty days on their voyage will be placed in quarantine, the duration of which will be determined by the state of health of the crew.

In Greece, all arrivals from the coast of Tunis are subjected to five days' quarantine.

Arrivals from Bordeaux are admitted into the port of Lisbon, subject, however, to rigorous quarantine.

All arrivals in Russian Black Sea ports from Italy or Spain are subjected to fourteen days' quarantine.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Gateshead (Urban).—We have recently commented at some length on this district in connexion with Dr. Barry's official report. Dr. Green's annual report refers to many of the conditions dealt with by Dr. Barry, and it devotes some attention to the question of infant mortality. This is evidently to an important extent induced by the faulty sanitary surroundings of the children. Many children are brought up in a single-roomed tenement which is overcrowded, which being occupied both by day and by night is never adequately ventilated, and which, with its offensive air, has to act as the place in which the infants' food is kept. The ignorance of the mothers in the lower grades of the population, and the consequent exposure and neglect to which infants are subjected, can probably only be dealt with as education is brought to bear upon the parents. Cellar dwellings in the town evidently need much attention. Many are very damp, and an effort is made to hide this by boarding up the damp walls. Yards are unpaved and sodden, and much squalor prevails in some of them. Infectious diseases caused 229 deaths in 1883.

Belper (Rural).—Mr. Gaylor, in his report on the Alfreton district, refers to the difficulties in providing a portable disinfecting apparatus. These difficulties are so great that some such stoves have since been made fixtures. A portable apparatus, where dry heat is used, is not easily made so that an equable temperature can be maintained. Lyon's steam apparatus is probably as efficient in its portable as in its fixed form, but it is ponderous. It would be far better for the authority to erect the infectious hospital they have long thought about, and to bring infected things to a disinfector, than to take a disinfector to the infected things in the different villages, where disinfection can rarely be effected without some carrying about of the articles to be dealt with, even if the apparatus is close at hand. Mr. Allen, in reporting on the Belper district, urges the provision of means of isolation, regarding it as absolutely necessary to proper sanitary work in the rural area. In both districts careful supervision of conditions affecting health is evidently observed.

Huddersfield (Urban).—One of the most useful forms of sanitary work is in progress in Huddersfield—namely, a house-to-house inspection. Dr. Cameron regrets that it does not proceed more rapidly, but the reason for delay is that so many unsuspected faulty conditions of drains, privies, &c., are constantly coming under notice. Herein lies the value of the inspection, and when it is completed the tabulated records of the work will at a glance enable the authority and their officers to perceive what sanitary circumstances are peculiar to any special area that may be affected with infectious disease. We wish that more systematic inspections of the same sort were in progress. The system of notification works smoothly. The number of cases of infectious disease which thus came under notice during 1883 was 154. Seventy-three cases were admitted into the sanitary hospital, and some doubtful cases were also reported to the medical officer of health. The death-rate, in a population of 84,450, was 21·4 per 1000 for the year.

Warrington (Urban).—In this urban district the death-rate for 1883 was 21·6 per 1000 living. Scarlet fever caused 26 deaths, whooping-cough 28, and diarrhœa 52. Enteric

Digitized by Google

fever attacked 22 persons, causing seven deaths. A full account is given of the sanitary circumstances associated with each case and of the remedial measures adopted. But after mere local conditions of premises had been dealt with all cause of disease could not be regarded as removed, and Mr. Gornall speaks very strongly as to the influence of sewer emanations in the production of this disease in Warrington, and he urges that remedial action should be taken as to so prevalent a source of danger. As the result of four years' experience, Mr. Gornall says that the system of notification of infectious diseases works most harmoniously. The injury to members of the medical profession, he declares, has been only fancied; private practitioners notify apparently most willingly, and this without any existing good relations between them and their patients being, so far as he can learn, in any way disturbed.

Liverpool (Urban).—Much has recently been said and written as to Liverpool as one of the principal centres of typhus in England, and as to its being one of the cities which is worst off for means of isolation. These matters have also been specially reported on by Dr. Stopford Taylor, and hence in his annual report for 1883 he only incidentally refers to them. The fact that dirt in connexion with conditions of overcrowding has so special a bearing on typhus gives interest, however, to Dr. Taylor's description of house accommodation and lodging, and we are glad to observe that a long list of insanitary dwellings has been reported to the Council as requiring to be dealt with. The number of insanitary houses purchased by the Corporation in 1883 was not large considering the state of many parts of the city, for 91 only were purchased, and of these 67 were demolished. The condition of the suburban houses is also a serious matter. There are as many as 15,266 on the register and 548 more were registered in 1883. The night visits paid to these houses led to the discovery of overcrowding in 1195 cases, and to the detection of a gross amount of indecent occupation, unmarried males and females occupying the same rooms in 660 cases, the number of total occupants of the several rooms varying from three to eight. These rooms also contained 467 children between the ages of five and thirteen years. This is one of the most difficult questions which authorities have to deal with, for any strict regulations strike too severely at the common use of a room by members of the same family, and either lax rules or the absence of rules lead to the result described. In Liverpool the matter can only be met in so far as overcrowding is produced, and 940 tenants were dealt with in that respect. The death-rate in Liverpool was 26·6 per 1000 in 1883. As regards hospital accommodation, the town council have at last taken the matter in hand; a large site by the riverside has been procured and tents have been erected. We could have wished that some more permanent building had been put up, but Liverpool was at the time in face of an emergency, and when the subject is deferred until the emergency arises it is not often that substantial buildings are constructed.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

During the week ending the 27th ult., 5681 births and 3209 deaths were registered in twenty-eight of the largest English towns. The annual rate of mortality in these towns, which in the five preceding weeks had declined from 25·6 to 21·0 per 1000, further fell last week to 19·1. During the thirteen weeks ending Saturday the 27th ult. the death-rate in these towns averaged 22·8 per 1000, against 20·6 and 19·9 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 14·4 in Norwich, 14·8 in Brighton, 15·8 in Huddersfield, and 16·1 in London. In the other towns the rates ranged upwards to 25·1 in Manchester, 25·2 in Halifax, 26·9 in Blackburn, and 28·8 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which in the five preceding weeks had declined from 1314 to 715, further fell to 611 last week; of these, 354 resulted from diarrhœal diseases, 67 from scarlet fever, 63 from "fever" (principally enteric), 48 from measles, 42 from whooping-cough, 24 from diphtheria, and 13 from small-pox. These diseases caused the lowest death-rates in Brighton and Portsmouth, and the highest in Cardiff, Preston, and Blackburn. The highest rates of mortality from measles were recorded in Blackburn and Preston; from scarlet fever in Sheffield and Cardiff; from "fever" in Newcastle-upon-Tyne and Salford; and from diarrhœa in Derby, Blackburn, and Wolverhampton. The 24 fatal cases of diphtheria in the twenty-eight towns included 14 in London and 3 in Liverpool. Small-pox caused 10 deaths in London, 1 in Liverpool, 1 in Sheffield, and 1 in Sunderland. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which in the eleven preceding weeks had steadily declined from 1368 to 471, rose again to 536 on Saturday last; the new cases admitted were 129, against 66 and 65 in the two previous weeks. The Highgate Small-pox Hospital contained 25 patients on Saturday last, 3 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 170 and 159 in the two preceding weeks, were 162 last week, and were 57 below the average. The causes of 68, or 2·1 per cent., of the 3200 deaths registered last week in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Nottingham, Hull, and in five smaller towns. The largest proportions of uncertified deaths were recorded in Birkenhead, Wolverhampton, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·5 and 20·8 per 1000 in the two preceding weeks, rose to 23·0 in the week ending the 27th ult., and exceeded by 3·9 per 1000 the mean rate during the same period in the twenty-eight large English towns. In the Scotch towns the rates last week ranged from 19·4 and 19·5 in Edinburgh and Leith, to 24·8 in Glasgow and 25·6 in Dundee. The 554 deaths in the Scotch towns included 52 which resulted from diarrhœal diseases, 24 from whooping-cough, 20 from "fever," 14 from diphtheria, 13 from scarlet fever, 8 from measles, and not one from small-pox; in all, 131 deaths were referred to these principal zymotic diseases, against 118 and 130 in the two preceding weeks. These 131 deaths were equal to an annual rate of 5·4 per 1000, which exceeded by 1·8 the average rate from the same diseases last week in the twenty-eight English towns. The deaths referred to diarrhœa, which in the two previous weeks had been 55 and 51, were last week 52, of which 16 occurred in Glasgow and 13 in Dundee. The 24 fatal cases of whooping-cough showed a further slight increase, and included 10 in Glasgow, 6 in Edinburgh, and 4 in Dundee. The deaths from "fever," which had been 10 and 15 in the two preceding weeks, further rose to 20, of which 15 were returned in Glasgow. The 14 fatal cases of diphtheria were 6 less than in the previous week, and included 6 in Glasgow and 4 in Dundee. The 13 deaths from scarlet fever included 9 in Glasgow, where 5 of the 8 fatal cases of measles were also recorded. The deaths referred to acute diseases of the respiratory organs in the eight Scotch towns showed an increase, but were 10 below those returned in the corresponding week of last year. The causes of 91, or more than 16 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which in the two preceding weeks had been 29·4 and 28·6 per 1000, rose to 30·2 in the week ending the 27th ult. During the thirteen weeks of the quarter ending last Saturday the death-rate in the city averaged 25·4 per 1000, the rate during the same period being 20·9 in London and 17·0 in Edinburgh. The 203 deaths in Dublin last week exceeded by 24 the number in the preceding week, and included 36 which resulted from the principal zymotic diseases, against 42 and 32 in the two previous weeks; of these, 16 were referred to diarrhœal diseases, 11 to scarlet fever, 3 to diphtheria, 3 to whooping-cough, 3 to "fever," and not one either to small-pox or measles. These 36 deaths were equal to an annual rate of 5·4 per 1000, the rate from the same diseases being 2·4 in London and 4·0 in Edinburgh. The deaths from diarrhœa, which had declined in the four preceding weeks from 48 to 21, further fell last week to 16. The 11 fatal cases of scarlet fever exceeded by 6 the number in the previous week, and the 3 deaths from diphtheria were higher than in any recent week. The 3 fatal cases of whooping-cough were within one of the number in the previous week, and the deaths referred to "fever" showed an increase. Eight inquest cases and 5 deaths from violence were regis-

Digitized by Google

tered in the city during the week, and 47 deaths occurred in public institutions. The deaths of infants showed a decline, while those of elderly persons corresponded with the number in the preceding week. The causes of 42, or nearly 21 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

MADRAS MEDICAL ESTABLISHMENT. — Surgeon-Major Robert William Cockerill, to be Brigade Surgeon.

ADMIRALTY.—Fleet Surgeon Thomas Robert Warren has been placed on the retired list, with permission to assume the rank and title of Deputy Inspector-General of Hospitals and Fleets.

The following appointments have been made:—Fleet Surgeon William J. Eames, additional, to the *President;* Staff Surgeon R. W. Biddulph, additional, to the *President;* Surgeon Otway P. Browne, M.D., to the *Asia;* Fleet Surgeon Edward Jones Butler, B.A., M.D., to the *Achilles;* Staff Surgeon James Robertson, to the *Brilliant;* Surgeon Frederick A. Trevan, to the *Indus;* Surgeon Theodore J. Preston, to the Royal Marines at Chatham; Surgeon Bowens S. Mends, to the *Téméraire;* Surgeon John L. Thomas, to the *Superb;* Surgeon David B. Bookey, to the *Hector.*

ARTILLERY VOLUNTEERS.—1st Sussex: Henry Habgood, M.D., M.R.C.S., to be Acting Surgeon.

Correspondence.

"Audi alteram partem."

THERAPEUTICAL REFORM.

To the Editor of THE LANCET.

SIR,—It is notorious that the coarse, nauseous, and bulky preparations of our official Pharmacopœia are passing out of date; and although we are anticipating the advent of a new edition, rumour says that it will not be a great improvement on the old, which no longer satisfies our requirements. There can be little doubt that it is not the dogmas of Hahnemann that attract many practitioners to homœopathy, and make it so popular with the public. It is the elegant method of administering remedies, the drop doses of powerful tinctures, and the pretty and dainty granules containing the active principles of the nauseous drugs which we employ, that entice those who administer and those who receive the treatment; these are the attractions which give life to the sect, and lend colour to their claim to a better therapeusis. The formation of a new sect is the natural result of every new discovery or advance in therapeutics, unless it is officially recognised and adopted by the profession; those who employ it become loud in their praises of it, and rapidly degenerate into quacks, indicating their possession of the new remedy by the adoption of a distinctive denomination; such persons speedily manufacture dogmas of their own to account for the miracles worked by their new idol. At the present day we see another such a sect developing before our eyes, and it is most instructive to watch its evolution. Because a certain Dr. Burggraeve has discovered a most elegant and probably useful method of dispensing the active principles of drugs in the form of granules, which are said to be accurately prepared, and to contain precise and efficient doses of the drugs, we have a new sect established, calling themselves dosimetric physicians, and issuing a journal of dosimetric therapeutics in which are recorded absurd and ridiculous accounts of how they "jugulate" disease by their new method; so that respectable practitioners are debarred from using new and probably useful drugs by the fear that they may lend countenance to those whom we are compelled to call "quacks" because they "talk noisily and boastfully" of their new method of curing disease.

Another great evil, brought upon us by the desire of our profession for improved therapeutical means and the absence of all official aid and guidance, is the shower of patent pills, pilules, and granules, poured upon us by the druggists. These enterprising gentlemen would compel us to prescribe "Messrs. Smith and Jones's No. 54 pilules," which they will dispense for us in a pretty little bottle, wrapped round with pink paper, on which are stated the various symptoms and diseases that "No. 54" and many other pills are likely to cure, so that on future occasions our fortunate patient may be able to select the number of the pill that he would prefer to take to cure the symptoms with which he may then be afflicted. Even in the case of those druggists whose dearest boast is their care for the interests and respect for the prejudices of the profession, we find ourselves introduced to a new materia medica and a complete pharmacopœia, and if we fail to commit them to heart we are denied participation in the "most recent advances in pharmacy."

It is true that these private enterprises have now provided us with excellent pilules and parvules, which profess to contain exact doses of the most active drugs and all conceivable combinations of them; but I would ask, what security have we for the accuracy and trustworthiness of these preparations? Unfortunately at present we have none, except such as may be found in the objectionable testimonials of those complaisant practitioners who are found willing, for the benefit of suffering humanity, to sing the praises of the particular druggist they employ.

Thus much of complaint, now for the remedy. An agitation has already been set on foot, having for its object the repeal of the Patent Medicines Stamp Act and the reform of the British Pharmacopœia. Both of these objects are desirable in their way, but neither of them strikes at the root of the matter. The repeal of the Stamp Act would still leave us face to face with a multitude of popular preparations of unknown composition, and with manufactured medicines of uncertain potency; while a reformed Pharmacopœia would require reforming at least every year; and although it directs how medicine should be prepared, it gives no guarantee that the medicines we use are prepared as it directs, or that they possess the potency it requires. We require to know that the preparations offered to us contain both the drugs and the exact doses described by their manufacturers, and that they are efficient and reliable. It is true that we could proceed under the Sale of Food and Drugs Act and have each specimen analysed for ourselves, but the process is a tedious and costly one, though no doubt much good might be obtained if the Act were enforced in a systematic and well-organised manner by some one or more of the medical corporations. The Government stamp which is now affixed to certain patent and imported medicines is of no advantage except as a source of revenue, and is often misleading to the public, who accept it as a guarantee of the genuineness of what is really an unknown article. Now, I would have all medicines stamped with a "hall mark" by an official pharmaceutical assay department. It appears to me to be practicable for the Government to establish an extensive analytical laboratory, in which all pharmaceutical preparations dispensed in this country, whether of home manufacture or imported, should be analysed, and if found efficiently and accurately prepared should be stamped and certified as genuine. The articles would be sent to the laboratory in bulk, a sample would be analysed, and the bottling and stamping would be performed while in bond. The charge made for stamping would be amply sufficient to cover the expenses of the laboratories, and would probably prove an important source of revenue to the State.

The examination and analysis of drugs should not be confined to the various pilules and granules offered for our use, but should extend to all imported or manufactured drugs or medicinal plants, as well as to all tinctures, syrups, extracts, cordials, &c. These, by being analysed and their mode of preparation registered, would become trustworthy and official preparations, although their manufacture might still be left to private enterprise, while the dispensing chemist would be provided with packets of drugs and bottles of tinctures on which he could rely, and which would bear upon them the data of their examination when they were found to possess the standard strength. Such a scheme as this would lead practitioners to use those attractive pilules and medicines which at present they admiringly gaze upon, but prudently hesitate to employ, preferring to rely upon the cumbersome and inelegant methods that have received official sanction and approval; it would also terminate the existence of those second-class chemists who, dealing with what are known as "second-class drugs," do not hesitate to imperil human life and render unavailing the services of the physician. The use of uncertified drugs for dispensing the prescription of a registered practitioner would become an

Digitized by Google

offence punishable by law. At the same time it might be enacted that really new improvements in pharmacy might still be patented for a certain period, giving the druggist the same advantages enjoyed by other tradesmen of profiting by his own discoveries, but that the composition of all patent medicines should be registered and published as a protection to the health and safety of the community.

The officials in charge of this department would probably be entrusted with the preparation of a Pharmacopœia, and we might look for a much more complete and efficient one than that with which we are familiar. This system would not interfere with or in any way repress the private enterprise of the druggists, but would rather encourage it, for I have no doubt that they would find the Government certificate of the accuracy of their preparations the strongest recommendation they could offer to the profession, and the surest means of obtaining an extensive sale for their wares. While those preparations which proved valuable would readily obtain the official recognition and be introduced into the Pharmacopœia.

I believe that if this plan meets with the general approval of the profession it only requires the united action of the various colleges, halls, and licensing bodies, together with the powerful advocacy of the medical press, to obtain the attention and aid of the present or any other Government. No corporate body can so properly and so powerfully move in this matter as the Royal College of Physicians of London, for not only does its charter confer upon the College the right to "supervise and examine all manner of medicines" used by physicians in London, but (by 32 Hen. VIII., c. 40) the College is enjoined to choose four censors from "the best learned, wisest, and most discreet" of the Fellows, who "shall and may, by virtue of this present Act, have full authority and power, as often as they shall think meet and convenient, to enter into the house or houses of all and every apothecary.....to search, view, and see such apothecary wares, drugs, and stuffs as the said apothecaries or any of them have or at any time hereafter shall have in their house or houses; and all such wares, druge, and stuffs as the said four persons shall there find defective, corrupted, and not meet nor convenient to be administered in any medicine for the health of man's body, the said four persons.....shall cause to be brent or otherwise destroy the same....."

The necessity for this inspection and examination of drugs which was felt in the reign of King Henry VIII. probably exists in no diminished degree to-day, and the College may feel that, though the same machinery is no longer competent to fulfil the duties and responsibilities imposed upon the College by statute, it is nevertheless incumbent upon it either to undertake these neglected duties itself or to urge upon the Government the adoption of some suitable method directed to attain the same end.

I am, Sir, yours faithfully,

Manchester-square, W., Sept. 27th, 1884. F. A. MAHOMED.

LUNACY LAW AGITATION AND SUICIDE.

To the Editor of THE LANCET.

SIR,—In your issue of June 28th last, and in your last number, there appeared singularly interesting letters from Dr. Adam under the above heading. To be read in connexion with those letters, will you be so good as to publish the following statement of facts.

"A month ago, a lady in this neighbourhood, aged between forty and fifty, became afflicted with acute insanity, marked by various delusions, and accompanied by threats of self-destruction. Her medical attendant advised immediate removal to an asylum. The husband signed the necessary order for admission; two medical practitioners, well known and thoroughly competent men, examined and certified the patient. But the proprietor of the asylum in which it was desired to place her declined to send nurses from his establishment to remove her from her home—naturally enough, after Mr. Justice Hawkins's dictum in a recent trial as to the law of trespass and assault. The medical attendant, more naturally still, declined to move: being of opinion that, having given his best advice, and having certified his patient, his duties ended there. The husband, over eighty years of age, and feeble in mind and body, was not capable of acting with the necessary vigour. The only other person who might have acted perhaps, though not related to the patient, refused, having doubts as to the accuracy of the diagnosis. The result was that, instead of being properly treated, in a suitable place, this unfortunate lady was found, a few days later, lying upon a neighbouring railway line, mangled and dead. She had left her home as though for a morning stroll, and had deliberately placed her head under an advancing engine. Mark that the disorder was in an early stage, and (to quote Dr. Adam) easily curable.

You, Sir, have favoured us in your journal of late with many disquisitions upon lunacy law and practice, most of them, let me assure you, galling beyond measure to those gentlemen who are engaged in this specialty. Will you ponder over the occurrence which I have related, and say where or with whom, in your judgment, lies the responsibility of this death—I had almost written, of this murder. Is it in the law or in Mr. Justice Hawkins's interpretation?

I am, Sir, yours faithfully,

Laverstock, near Salisbury, Sept. 29th, 1884. H. J. MANNING.

*** The fault in this case was obviously that of the friends. The certificates being signed, it was for the friends to take the case to the asylum. If the friends of a sick woman had an order for her admission to the hospital, and while they were wasting time she became delirious and jumped out of window, no one would think of blaming the hospital staff for the accident; still less could the benevolent giver of the admission note be blamed. Surely it is no part of a medical man's business to take his patients to an asylum. It is this fussy interference with patients that discredits medicine and degrades the profession. Let practitioners remember that they are neither "touts" for asylums nor agents for the removal of refractory lunatics. It is work for which they are unfitted. The way in which insane patients are coerced or cajoled into asylums is most discreditable. The whole blame in this case rests with the friends. We think the managers of the asylum and the medical men concerned acted most judiciously. The neglect of the friends was culpable. It is nothing to the point that the husband was eighty. When a medical man exceeds his duty he lowers his professional character and places himself in a false position.—ED. L.

"BICYCLE RIDING AND PERINEAL PRESSURE: THEIR EFFECT ON THE YOUNG."

To the Editor of THE LANCET.

SIR,—Mr. H. A. Allbutt accuses me of bringing forward in my paper on this subject unfounded theories "entirely unsupported by facts." The letter of Dr. G. Herschell published by you at once disposes of this accusation. Mr. Allbutt asks whether I "have met with a single case of perineal mischief, the result of cycling, within the last ten years." In reply, I beg to inform him that I have met with such a case within the past six months. I am not in general practice, and so have little opportunity of meeting with such cases, but perhaps if a few general practitioners would be so kind as to relate their experiences in this matter, it would be found that, even at this early day in the era of cycling, there are sufficient grounds for calling attention to the *excessive* use of these machines as at present constructed by growing, undeveloped boys. I was not aware until now that a "healthy look and jolly manner" were sure tokens of virtue in young men; neither did I infer in my paper, as Mr. Allbutt assumes I did, that the results of cycling mentioned were to be found in the young-men cyclists of to-day, who were, most of them, young men before they mounted a machine. It is ten years hence that we are to look for the results of the excesses of to-day, when our boy-cyclists of ten, twelve, and fourteen have reached man's estate, or what immoderate cycling has left them of that heritage.

Mr. Allbutt's concluding argument against my paper—viz., "that it may injure an industry which is giving employment to thousands"—is weak. The "drink traffic," as it is called, gives employment to hundreds of thousands, yet I am afraid that fact would hardly be received as an argument in favour of silence on the subject of drunkenness. By-the-bye, cycling and drinking are somewhat alike. Moderate indulgence in either does little harm and sometimes positive good; in both there are great inducements to

Digitized by Google

excessive indulgence, and when excess in either steps in health rushes out by the other door.

Whether a saddle, such as Dr. Herschell suggests, can be devised is doubtful, for when the thigh is extended, as it is in riding large bicycles, the ischial tuberosity projects very little past the posterior line of the femur; and when the hamstring muscles become tense the tuberosity as such is abolished and an almost vertical plane takes its place.

I am, Sir, yours faithfully,
S. A. K. STRAHAN, M.D.

Berry Wood, Northampton, Sept. 1884.

To the Editor of THE LANCET.

SIR,—The alarmist tone that characterises Dr. Strahan's article on cycling, and the formidable indictment it contains against a popular sport, lose much of their force when it is seen that they are due to theoretical considerations alone. Dr. Strahan may have met with cases which appear to beat out his contentions, but if so, I venture to believe that his experience is a very exceptional one. It is possible that to a youth already morbidly sensitive from past vicious indulgence the saddle friction involved in riding may be injurious. But given a fairly healthy lad there is no doubt, as Mr. Allbutt ably argues in your last issue, that the beneficial influence of cycling on the physical condition generally is more than sufficient to outweigh and to nullify any slight local excitation such as may possibly arise in a limited number of cases. As to the comparison between horse-riding and cycling, it is beyond all question that the local "stimulation" is far greater in the former than in the latter. The motion and pressure involved in equitation, especially in beginners, are distinctly more suggestive and provocative of erotic sensations than those to which the cyclist is subjected. On this point strong evidence was but quite recently adduced in my hearing by a well-known bicycle rider, who is also an accomplished horseman. With regard to the "spinal shocks," made much of by Dr. Strahan, their influence is of a still more hypothetical nature than that of the perineal pressure. Careful statistical inquiry has, I apprehend, still to be made, but speaking from a very large acquaintance with cyclists, ranging in age from five to sixty years, I agree with Dr. Allbutt in joining direct issue with Dr. Strahan. Abuse there undoubtedly is of cycling, as of everything else, leading chiefly, as in all forms of athletic exercises, to damage of the thoracic viscera; but beyond this the sweeping charges of Dr. Strahan seem to be almost devoid of support. And when it is considered that the vast majority of cyclists are middle-class men and lads, cooped up in towns and largely employed in insanitary places and occupations, it is almost impossible to overrate the advantage accruing to society from the popularisation of the sport in question. Before it came into vogue, that dreariest of occupations to the average man, "taking a constitutional," was practically the only means afforded such an individual of getting exercise. Now we have provided for us an attractive therapeutic means of combating directly some of the most prominent evils incidental to town life; under its influence dyspeptic troubles disappear, the brain clears, mental morbidity merges into optimism, a new interest in life is created; in short, unless the hobby is literally ridden too hard the result is, as far as my observation goes, wholly beneficial. In point of fact, even when indulged in to an extreme degree, cycling is singularly free from the dangers that accompany most forms of athletic exercises. As an illustration I would adduce a case I have under observation at present, that of a confirmed gouty subject, who has suffered for years from exceedingly well-marked aortic stenosis and regurgitation, yet until very recently my patient has been an enthusiastic tricyclist, without, at any rate, any subjective inconvenience whatever. In fact, he declares that at the end of several hours' run he almost invariably felt better than when he started, and is inclined to resent the embargo I have laid upon the use of his machine for the future.

Permit me to mention one other case in conclusion, that of a gentleman aged sixty, who a year or two ago was fast sinking into the listlessness and degenerative condition generally of old age. It is hardly too much to say that the judicious use of the bicycle—one of the "safeties"—has "renewed his youth"—at any rate added zest, and, in all human probability, years, to his life.—Yours truly,

Brockley, September, 1884. J. S. BOOTHROYD, M.D.

OVER-PRESSURE IN SCHOOLS.

To the Editor of THE LANCET.

SIR,—In dealing with the question of over-pressure in schools, it appears to me that in regard to elementary schools at least one very important factor has been omitted in the consideration of the question generally.

It is admitted that the alarm of over-pressure has been more brought to the front of late years, in fact, it is only for the last very few years that it has been an object of public attention. Over-pressure in reference to pupil teachers attracted more notice in the earlier days of the Education Act, and it was not without good cause that relaxations were made for the relief of these young persons.

The point that I think has been overlooked is that, owing to the compulsory attendance of all children, a great number of boys and girls are obliged to attend school who, in the absence of compulsion, would be kept at home or sent to dames' schools owing to weakness or delicacy of constitution. It is probably owing to the presence of these children in the school that so many cases of breakdown are met with at this time. It is far from being proved that the present high pressure system of teaching turns out better children than the former less pretentious system did. I call to mind numerous instances of the sons of artisans and of poorer parents than the average workman, who under the old code, and even before the code, were so taught as to enable them to take up positions of trust and importance in after-life.

My experience of over-pressure in public schools differs *in toto* from that of Mr. Barford as stated in THE LANCET last week. It is a matter of constant observation that the boys here look better and bonnier at the end of the term than they do on their return from their homes. There may be, and no doubt there are, some boys who require attention on their return from school, yet, on the other hand, there is always at the beginning of a new term a number of boys who are not well enough to return to their work. That number I find is usually greatly in excess of the number of boys out of school from illness during the term. There must, in a population of five or six hundred, whether boys or men, be a certain percentage of more or less feeble constitutions, who are ailing or on the sick list without the smallest amount of over-pressure in the matter of work.

I am, Sir, yours very truly,
Marlborough College, Sept. 29, 1884. WALTER FERGUS.

"THE UNCERTAIN COMPOSITION AND ACTION OF GREY POWDER."

To the Editor of THE LANCET.

SIR,—Many years ago, at least twenty, I called attention in the *Indian Medical Gazette* to the tendency of the mercury in this preparation to assume the dangerous form of red oxide, and especially in a warm climate. I find as a matter of experiment that mercury with magnesia is perfectly stable provided pure mercury be used and no other ingredient added to the magnesia carbonate to expedite the minute division of the mercury, which must be effected by long-continued trituration; it is immaterial whether the light or heavy form of magnesia carbonate be used. I may remark that blue pill in suspension can be most conveniently given to infants.

I am, Sir, yours truly,
Totnes, Sept. 27th, 1884. H. COOKSON, F.R.C.S., Surgeon-Major, Indian Army (retired).

SALTS OF IRON.

To the Editor of THE LANCET.

SIR,—In prescribing salts of iron for patients I am constantly met with the inquiry, Will the teeth be injured by the medicine? There is a wide-spread belief among the laity that preparations of iron are injurious to the teeth, a belief which is also fostered by dentists. In some instances the prejudice amongst patients is so strong that a great difficulty arises in the matter of treatment when iron is indicated, especially in those cases, by no means rare, in which patients declare they cannot take pills. I suppose the blackened condition of the tongue and teeth, which is often seen after salts of iron have been taken, is due to a deposit of the sulphide of iron. Is this injurious to the teeth

Digitized by Google

if not removed? If so, what is the nature of its action? I shall be glad of any expression of opinion on the part of your correspondents. The general question of the action of food and drugs upon the teeth is an interesting and important one. For instance, is sugar injurious? What is the risk also to the teeth in taking acids as tonics? I am, Sir, yours truly,

Doncaster, Sept. 27th, 1884. JAMES W. SMITH.

*** Mr. Coleman, in his "Manual of Dental Surgery," says: "The effects of administering medicines, especially acid ones, have by some been considered important factors in producing dental caries. We believe that it has been overrated; at the same time the long continuance of acid medicines renders such secretions as the saliva abnormally acid; and the direct contact of such acids as phosphoric, hydrochloric, and nitric may no doubt in time affect the teeth, as they certainly do certain kinds of metallic fillings in them. The common practice of employing a tube when taking acid medicines is of but small advantage compared with a thorough rinsing of the mouth with a solution of bicarbonate of potash or soda afterwards." Mr. Coleman does not refer to iron, but it may almost be taken for granted that the *remedies* are not nearly so hurtful to the teeth as are the *maladies* for which they are administered. See also Tomes' Dental Surgery, second edition, page 731.—ED. L.

"THE EXAMINATION OF SURGEONS-MAJOR."

To the Editor of THE LANCET.

SIR,—I have been considerably amused at the estimate which the ex-President of the Royal College of Surgeons of Ireland has formed of the value that a knowledge of operative surgery and practical medicine is to surgeons-major in the army. He appears to consider this, in their case, to be on a parallel with a knowledge of the goose-step to a lieutenant-colonel. This would scarcely seem an adequate illustration of Mr. Wheeler's own attainments and position as the surgeon of a large hospital and ex-President of a Royal College of Surgeons. He protests against the insult to a surgeon-major implied in his having to undergo an examination to show his fitness for promotion from the executive to the administrative rank. The Director-General may fairly desire to have some assurance on this point before taking the responsibility of recommending him for promotion on the grounds of ability and merit. But then, think of testing an officer of twenty years' service as to his knowledge of operative surgery and practical medicine! The ex-President must, I imagine, have been subjected to something of this kind, so far, at least, as surgery is concerned, before he was admitted to the honour of the Fellowship of the Royal College of Surgeons of Ireland. Why do not those "elderly victims" avoid the indignity of the proposed examination by following the excellent example which he has set them in this respect? It seems to be intended that medical officers possessing the Fellowship of any Royal College of Physicians or Surgeons granted under a higher standard of qualification than that for licentiate or member, will be exempted from examination in medicine and surgery. The Director-General does not seem to have adopted the idea of a one-portal system, but, in accordance with the views of Professor Huxley, and I believe also of Mr. Wheeler himself, appears to be perfectly satisfied with the qualifications to be obtained from any of the recognised Colleges. Perhaps Mr. Wheeler is not aware that middle-aged medical officers of the German army were competent a few years ago to go through a course of operative surgery under Professor Langenbeck, and were ordered to Berlin for that purpose.

I am, Sir, your obedient servant,

September, 1884. K. Y. Z.

THE STATE OF THE WEY.—The Guildford Rural Sanitary Authority have called the attention of Messrs. Spicer to the general opinion that the poisoning of fish in the river Wey was caused by an influx of some deleterious matter from their paper mill, and have ordered a careful inspection of the river to be made by the medical officer of health.

NEWCASTLE-ON-TYNE.

(From our own Correspondent.)

THE SANITARY CONDITION OF NEWCASTLE.

OUR medical officer of health, Mr. H. E. Armstrong, has just issued his report on the sanitary condition of the city during the past year. This work of Mr. Armstrong's is too elaborate to be dealt with in this letter, but it is sufficient to say that it bears every mark of industry on the part of the writer, and shows besides a full and accurate knowledge of the working and requirements of the departments under his charge. Great care is shown in the compilation of the various tables and statistics throughout the report, which is likewise accompanied by very clear maps showing the portions of Newcastle at which scarlet fever, small-pox, enteric fever, and typhus appeared during the year, distinguishing the fatal and non-fatal cases. As to infectious diseases, he reports that there had been notified to him by practitioners in the city 2032 cases, and he remarks that as far as he can judge, "the notification clauses of the Newcastle-on-Tyne Improvement Act, 1882, are working, and are likely to work, smoothly, and with the satisfaction of the inhabitants." Mr. Armstrong shows very forcibly in his report that the most striking fact disclosed in the infectious diseases inquiry is the generally imperfect character of the separation made between the sick and healthy, even in large private houses and middle-class ones, and he asks what is to be expected in the case of tenemented houses of one, two, or three rooms, of which there are several on the same stair and scores in the same street. One inference he thinks is plainly deducible from the facts brought out in his report—namely, "that the greater prevalence and tendency to spread of the diseases in question"—in the densely populated districts—"is due to the fact that for the working-classes no such thing as home isolation of the infected sick is possible," and he further asks, "Ought this to be allowed? Have the public the right to protection from the danger to which they are exposed from such a state of things? Should not those authorities who provide accommodation for the fever-stricken have the power to insist on their removal from such unhealthy areas for the good of themselves, their relatives, neighbours, and the public in general." Speaking for myself as a practitioner, and from what I know of the feelings of other practitioners who have much contact with the working classes, I would answer Mr. Armstrong's questions by saying "No" to them all. Before he gets this summary medical jurisdiction for our poor I think it will be in common justice incumbent for our authorities to provide healthy dwellings for the working classes; for in town improvements they are little considered, but every so-called "improvement" packs the poorer classes more and more, and makes their condition worse than before. Far too little prominence is given to this aspect of sanitation.

NEWCASTLE WORKHOUSE AND ITS MEDICAL OFFICER.

As might have been expected from the increase of our city population, the Newcastle workhouse and its hospital have together expanded very much the last few years. Mr. N. Hardcastle has held the arduous post of medical officer for a great many years, spending a considerable but still a necessary time every morning in the performance of his duties, and liable at any time to be summoned to attend in urgent cases. Quite lately the guardians have—as a "fad"—requested him to attend at least twice daily, but without any augmentation of his stipend. Mr. Hardcastle stated, while asking for additional remuneration, that at various unions this duty was found to be quite unusual, and in asking for consideration, he points out that the labour involved in such visit requires him to compass some 700 or 800 miles annually. Mr. Hardcastle's request is a perfectly reasonable and just one, and ought to be at once complied with, or the guardians should provide him with a resident assistant.

Since the above was written the question has come up for settlement by the guardians. The House Committee reported against any increase, and, this being supported by the "economists," was carried by a majority of one. It was mentioned during the discussion that Mr. Hardcastle had acted as medical officer to the workhouse for twenty-nine years without a complaint. The feeling I hear expressed on all sides as to the action of the guardians in the matter is surprise at their shabby behaviour to an old officer, at the

Digitized by Google

same time it is felt and believed that ere long the board will give Mr. Hardcastle the advance he asks as an act of bare justice.

Newcastle-on-Tyne, October, 1884.

GLASGOW.

(From our own Correspondent.)

THE OUTBREAK OF ENTERIC FEVER IN THE HOSPITALS.

DR. RUSSELL'S report on the outbreak of enteric fever in the Glasgow hospitals is one of the most interesting and valuable documents of its kind ever presented to the public. It shows three things very clearly—the excellence of the methods of investigation pursued by our sanitary authorities, how entirely the Public Health Acts are set at nought by the rural authorities in Scotland, and how great are the risks to which large urban populations are exposed from the culpable neglect of these rural authorities. This outbreak occurred suddenly and simultaneously in our three large hospitals, the Royal and Western Infirmaries, and the Belvidere Fever Hospital, institutions situated at long distances from each other, entirely separate as to drainage, and agreeing only in the source of their water-supply and their milk-supply. The former (the water-supply) was excluded, as the outbreak did not extend to the city generally. The milk for these institutions is obtained through an agent from about forty different farms, and investigation showed that at one of these farms—Fergushill, near Kilwinning—all the conditions prevailed which would favour the conveyance of the fever poison in the milk sent to town. There had been a patient suffering from fever on the farm. Enteric fever had been epidemic in the adjoining villages for over two years, and the water-supply of the farm was found to be extremely defective, while the streams from which the cattle drank received the sewage of the infected villages, and had caused a considerable mortality among the farmers' cows. The chain of evidence is thus complete. This I understand to be the second occasion on which disease of this kind has been sent from the same district to Glasgow. The present epidemic has so far involved 104 persons: 44 in the Western Infirmary, of whom 10 are males; 31 in Belvidere; and 29 at the Royal Infirmary. The disease is telling with special severity on the scarlet fever patients in Belvidere. In addition to those occurring in hospital, a few have been traced in the city among persons recently discharged from hospital. After referring to the notoriety of the bad sanitary condition of Kilwinning, Dr. Russell's report to the Town Council concludes thus: "The Local Authority put the circular [issued by the Board of Sanitary Supervision specifically upon the sanitary condition of dairy farms] in their waste basket, and it has been left for you, in self-defence, to obtain these analyses. It now remains for you to forward the results to the Board of Supervision in the hope that some means may by it be found to compel the Local Authority to do their duty. It is by such by-paths that cholera will find its way into our large cities." It would be interesting, if it could be ascertained, what was the nature of the feverish disease from which the farmers' cows suffered, as there is, so far as I am aware, no authentic recorded case of typhoid fever in the cow." The situation would not have been complete without the occurrence of a squabble at the Royal Infirmary. A difference of opinion arose between the medical staff and the managers as to the infectiousness or non-infectiousness of enteric fever; but, somewhat unusually, this difference of opinion seems to have been settled in favour of the view held by the staff.

IRELAND.

(From our own Correspondent.)

SANITARY CONGRESS AND EXHIBITION.

THE Sanitary Congress commenced last Tuesday. At one o'clock luncheon took place, and at three the Health Exhibition was formally declared open. At eight P.M. the inaugural address was delivered by the President, Sir Robert Rawlinson, C.B., in the lecture theatre of the Royal Dublin Society. His Excellency the Lord-Lieutenant was present at the banquet given on Thursday evening at the Shelbourne Hotel.

A BONE-SETTER IN TROUBLE.

An important case affecting that class of the community who believe implicitly in the skill of the local bone-setter was under investigation at New Pallas, county Limerick, last week. Some time since, a boy fell off a donkey and broke his arm; the services of a bone-setter were obtained, who put up the fractured limb; gangrene, however, set in, and the boy died. Dr. John Ryan, the medical officer of Grean dispensary, deposed at the inquest that he had examined the child, and that in his opinion death had resulted from gangrene of the arm caused by extreme pressure, in consequence of the parts having been bandaged too tightly. The jury found a verdict to this effect.

THE SEWAGE OF DUBLIN.

Sir Robert Rawlinson, C.B., in returning thanks for his inaugural address as President of the Sanitary Institute of Great Britain, at the Sanitary Congress held in Dublin this week, said he had, with Dr. MacCabe, in 1879, investigated the sanitary condition of Dublin as to its sewerage and drainage, and the state of the Liffey. He did not wish to paint Dublin in colours blacker than it deserved, but he was bound to say that there was a great deal to do as regards its sanitary condition which was absolutely necessary. He was of opinion that out to sea must go the whole of the crude sewage of Dublin, because the river Liffey must be purified, and intercepting sewers, having a sea outlet, would be the cheapest remedy. No city in the world was perfect as regarded its sanitary condition, and therefore the motto of sanitation must be, "Unceasing work, unceasing care, and unceasing attention."

FREE LIBRARIES IN DUBLIN.

The seventh annual Congress of the Library Association of the United Kingdom was commenced last Tuesday at Trinity College, when the opening address was given by Dr. Ingram, librarian to Trinity College. On the following day the new Free Libraries at Capel-street and Thomas-street were formally opened by the Lord Mayor, and in the evening a conversazione took place at the Mansion House.

THE DUBLIN ORTHOPÆDIC HOSPITAL.

The supporters of this institution, in consequence of the increasing demands for admission and the absolute necessity for additional room, so as to provide further accommodation, have secured new premises. The new hospital will be in Great Brunswick-street, and provision will be made so as to accommodate fifty inmates. The necessary alterations are nearly completed, and in a short time the inmates at Ushers Island will be moved to the new hospital in Brunswick-street.

His Royal Highness the Duke of Cambridge, while on a visit to Dublin this week, inspected the Royal Military Hospital and the Female Hospital for the Wives of Soldiers. Before his departure from the latter he wrote a memorandum in the visitors' book, stating that he found it in every respect in excellent order, and most creditable to the matron and those in charge.

From the annual report of the Registrar-General for Ireland for 1883 it appears that the births registered during the year were 118,163, and the deaths 96,228, a number equal to 1 in 52·1, or 19·2 per 1000, of the population. The emigrants numbered 108,724, and the estimated population to the middle of the year was 5,015,282.

The Local Government Board has sanctioned the appointment of Dr. Donovan as medical superintendent officer of health for the City of Cork.

Dublin, Sept. 30th.

PARIS.

(From our own Correspondent.)

THE LAICISATION OF THE HOSPITALS.

M. QUENTIN, the Director of Public Assistance, has, owing to some disagreement between him and the Prefect of the Seine respecting the work of laïcisation in the hospitals, resigned his office, and is to be succeeded by M. Cazelles, Prefect of the Bouches-du-Rhône. M. Quentin wanted to complete the laïcisation of the hospitals without further delay, but M. Poubelle, the prefect, found it expedient to put a check on the operation, as the Government has found

Digitized by Google

to its cost that the class of women from whom nurses are recruited are quite unsuited for the care of the sick in the hospitals. Several irregularities having been brought to the notice of the authorities regarding the conduct of the "infirmières," which contrasted so unfavourably with that of the Sisters of Charity, it has been found necessary to put a restraint on the extreme measures hitherto carried out in some quarters in the work of laïcisation, and an instance has just occurred at the Hôtel Dieu at Auxerre, at which the disorderly conduct of the infirmières was so notorious that the Town Council thought proper to propose their dismissal and the reinstatement of the Sisters of Charity. The most remarkable feature of the affair was that the proposition emanated from the ultra-Radicals, who are also town councillors, and which was unanimously agreed to by the commission ordered to investigate the matter. Another reason alleged for the proposed change is that in the event of an outbreak of cholera, patients and officials would be found in a painful predicament without the Sisters of Charity in the hospitals, as was only lately exemplified at Toulon and Marseilles and other cholera-stricken districts, where the Sisters were recalled and their devotion and self-denial fully recognised.

M. Waldeck-Rousseau, the Minister of the Interior, has been laid up with a rather severe attack of rheumatism. He is now convalescent, and though not yet allowed to leave his room he is sufficiently well to transact the duties of his office.

The holidays being over, the reopening of the schools has just begun, and strict orders have been given that the state of the health of the pupils returning from the provinces should be rigorously inquired into, particularly of those coming from the cholera-stricken districts.

Paris, Oct. 1st, 1884.

CANADA.

(From a Correspondent.)

ASYLUMS AND LUNACY LAWS.

THERE has been a good deal of excitement in Montreal over the case of a young woman who has been for two years in the Long Point Asylum, although some of her friends assert that she has been perfectly sane during the whole period. The case of Ward, who was imprisoned in the same asylum some time ago by his wife, is a notorious example of false deprivation of liberty. The Lunacy Law in Quebec is very lax. The Ontario law, some years ago, was almost a reprint of the British statute. It has, however, been greatly altered and improved. Formerly the finding of two physicians was sufficient for a commitment, and this could be rather easily obtained. Suppose the family physician stated the facts of the case to another physician, who, placing confidence in his statements, might at his pleasure fill up the required papers without making a personal examination at all. Now, however, the examinations must be made by two physicians independently of each other, the family physician not being eligible. These medical men must not be partners, or father, brother, or son of persons interested in the institution. Their findings are submitted to the superintendent, who makes a separate examination on the admission of the person to ascertain the truth of the statements on which the charge is founded. With regard to private asylums the law is still more stringent. There must be the preliminary examination by two physicians. For each institution there is a board composed of the county judge, the county warden, the clerk of the peace, and the Government physician. The medical superintendent must report to the clerk of the peace within six days from the admission of a patient; the clerk must submit the report to the board. An examination is then made, and if there be no good grounds for restraint, the party is released. Should there be doubt in the matter, a second examination is ordered at an early date to avoid liberating a suspected person during a lucid interval.

CANADA MEDICAL ASSOCIATION.

This Association held its annual gathering in Montreal on August 25th, 26th, and 27th. The meeting was well attended, and much interest taken in the proceedings. Undoubtedly this was the most successful meeting the Association has ever had. All were eager to hear Mr. Lawson Tait's address on Abdominal Surgery, and none were disappointed when they did hear it. Some of the more recent utterances on abdominal surgery of Sir Spencer Wells came in for rather sharp criticism. Among the visitors at the Association from the United Kingdom may be mentioned Mr. Tait, Dr. McMillan of Hull, Dr. Heywood Smith, Dr. George Harley, and Dr. Protheroe Smith of London, Dr. Struthers of Aberdeen, and Dr. MacAlister, editor of the *Practitioner*. The banquet at the Windsor Hotel was excellent in every respect, and reflected great credit upon the hospitality of the profession in Montreal. The feast was presided over by the sage professor, Dr. Hingston of Montreal. The speeches of the British members were listened to with great attention. Wm. Osler, M.D., F.R.C.P., was chosen president for 1885, and the place of meeting, Winnipeg, Manitoba.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The meeting of this Association, which was held this year in Montreal, was a grand success alike in point of numbers, in the excellence of the papers, and in the general programme of amusements. First, there came the civic welcome, delivered by Major Beaudry in Queen's Hall to a large and brilliant audience. Sir John A. Macdonald, Premier of Canada, then addressed the meeting briefly, and congratulated the Association in coming to this country and the country on being favoured by so distinguished a visitation. The Marquis of Lansdowne, Governor-General, and a member of the Association, made a few well-chosen remarks, in which he expressed the hope that so many eminent scholars coming to this country, from different parts in Great Britain, would have a strong influence in binding the Dominion and the mother country more closely than ever. The President, Lord Rayleigh, then delivered his inaugural address. He travelled over a wide field in the course of his remarks, and called special attention to the fact that they would all go back to Britain with extended views regarding the country in which they had met for the first time. He dwelt fully on the dynamo-machine, and was hopeful that the time was near when electricity would be much more utilised than at present.

Many of the members of the Association, after the close of the session in Montreal, paid a visit to Toronto, where they were greeted by a civic address of welcome. The visitors then entered upon their drive to points of interest in the city, and arrived finally at the Government House, where a garden party was held.

Medical News.

ON Tuesday last the memorial stone of the new extension to Bradford Infirmary was laid by the Mayor of Bradford.

ROYAL COLLEGE OF SURGEONS.—The Library and Museum of this institution were reopened on Wednesday last, the 1st instant.

THE master of a British ship has been fined £4 at Cardiff for concealing the fact that there was an epidemic of scurvy on board his vessel.

AT the visit of the Duke and Duchess of Edinburgh to Hull this week, their Royal Highnesses laid the foundation stones of new wings to the infirmary of the town.

THE Freemasons belonging to the several lodges in Hertfordshire have erected in the Watford Cemetery a marble cross to the memory of the late Dr. F. H. Wilson Iles, deputy provincial grand master.

THE Gresham Lectures on Physic will be delivered by Dr. Symes Thompson in the theatre of Gresham College, Basinghall-street, on Tuesday, October 7th, and three following days.

THE CARTWRIGHT PRIZE.—This prize of the Alumni Association of the College of Physicians and Surgeons of New York, consisting of $500, will be awarded at the commencement of 1885 to the authors of the best medical essay upon any subject. The essays, which must contain the results of original investigation made by the writer, are to be sent in to the prize committee, of which Dr. R. W. Amidon, 18, West Twenty-first-street, is chairman, before April 1st, 1885.

Digitized by Google

COLLECTIVE INVESTIGATION.—A special meeting to further the above object will be held in the Board-room of the Guildford Hospital on Thursday, October 9th, at 3.30 P.M., Jonathan Hutchinson, Esq., in the chair. There will be a discussion upon the subject of "Chorea and Acute Rheumatism." Specimens of bacteria will be shown by Messrs. Beck of Cornhill. A display of instruments will be exhibited by Messrs. Arnold and Sons.

ST. JOHN AMBULANCE ASSOCIATION.—A class at Parkhurst Prison, Isle of Wight, instructed by Dr. Arthur Price, has undergone examination by Surgeon Major V. Wearne, A.M.D., and the Governor, Major F. H. Noott, and seventeen warders have been reported to St. John's Gate as thoroughly competent to render "first aid to the injured." The Countess of Strathmore presented 358 certificates to the Dundee classes on Friday, and Lord Egerton of Tatton presided at a meeting at Stockport on Saturday to open the ensuing session.

THE METROPOLITAN ASYLUMS BOARD.—At the meeting of this Board on the 27th ult., returns were presented showing that during the four weeks which had elapsed since the interim meeting of the managers 319 fresh cases of small-pox had been received into the asylums from the districts of the metropolis, as against 295 in the previous four weeks. The fever returns showed that during the fortnight 249 fresh cases of fever had been received, as against 239 in the previous month. A tender of £79,000 for the erection of a convalescent scarlet fever asylum at Winchmore-hill was, being the lowest, accepted.

SCHOLARSHIPS AND EXHIBITIONS.—At University College the examiners recommend the following for medical entrance exhibitions: £100, H. Caiger; £60, H. M. Fernando; £40, S. V. J. Brock.—At Guy's Hospital the entrance scholarship of 125 guineas in Arts has been awarded to Mr. Alfred Parkin, and that of 125 guineas in Science to Mr. James McDonald Gill.—At St. Mary's the scholarships in Natural Science of £75 each have been awarded to Mr. W. G. Holloway and Mr. F. W. Lewitt, and those of £50 each to Mr. C. Graves, Mr. A. M. Hickley, and Mr. C. G. Mack.—At the London Hospital the entrance scholarship of the value of £60 has been awarded to Mr. William S. Fenwick; and that of the value of £40 to Mr. J. H. Sequiera.

THE HAMPSTEAD SMALL-POX HOSPITAL.—At the last meeting of the Hampstead Vestry, a report from Dr. Gwynn, the medical officer of health, on the subject of the spread of small-pox in the parish since the reopening in May last of the Metropolitan Asylums Board Hampstead Hospital for the reception of small-pox cases, came under consideration. Dr. Gwynn's report showed that from May to September, 1884, eighty-nine houses in the whole parish were attacked with small-pox, thirty-three of which were within a quarter-mile circle of the hospital wards, and twenty others between the quarter- and half-mile circle, houses of all classes being attacked. Against these facts was placed a return showing that in the whole of 1881, when small-pox was prevalent in the metropolis and when this hospital was closed, only thirty-six houses in the parish were attacked, but four of which were within the quarter-mile circle of the hospital wards, and only eight others between the quarter- and half-mile circle. After considerable discussion it was resolved to memorialise the Local Government Board to hold an inquiry into the statements contained in the report.

BODY, H. MARTEN, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Tedburn St. Mary District, St. Thomas's Union, Devonshire, vice Renwick, resigned.

BULL, G. COULSON R., F.R.C.S., M.B., L.R.C.P.L., has been appointed Resident Pathologist and Registrar to the General Hospital, Birmingham.

CARNELLEY, MATTHEW, L.R.C.P.Lond., M.R.C.S., has been appointed Certifying Factory Surgeon to the District of Ruddington, Notts, vice Hall, deceased.

COOPER, ALFRED, F.R.C.S.Eng., L.S.A.Lond., has been appointed Consulting Surgeon to the West London Hospital.

CRIPPS, C. COUPER, M.B., M.S.Durh., M.R.C.S., has been appointed House-Physician to the Hospital for Women, Soho, vice Felix Vinrace, M.D., resigned.

DEAN, FRANCIS, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Workhouse, Northleach Union, vice Webb, resigned.

FLECK, WILLIAM, M.D.Q.U.I., M.Ch., has been appointed Medical Officer to the Workhouse, High Wycombe Union, vice Hayden, resigned.

FURSE, EDWIN, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Workhouse, South Molton Union, vice Flexman, resigned.

GINDERS, ALFRED, M.D. St. And., L.R.C.P.Ed., San. Sci. Cert. Camb., has been appointed Government Medical Officer and Public Vaccinator for the District of Tauranga. Also Health Officer for the Port of Tauranga, Bay of Plenty, New Zealand.

KELTY, WILLIAM, M.B., Ch.M.Aber., has been appointed Government Medical Officer and Vaccinator for the District of Carcoar, New South Wales.

MOXON, HENRY JAMES, L.D.S.Lond., has been appointed Dental Surgeon to the London Female Penitentiary.

ROBINS, GEO. NORMAN, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Rippingdale District of the Bourn Union, Lincolnshire, vice Adams, resigned.

ROGERS, WILLIAM HENRY, L.F.P.S.Glasg., has been appointed Surgeon to the Cobar Hospital, New South Wales.

SCOT-SKIRVING, ROBERT, M.B., Ch.M.Ed., has been appointed Hon. Physician to Prince Alfred Hospital, Sydney.

SHONE, WILLIAM JAMES, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer and Public Vaccinator for the Little Marlow District of the High Wycombe Union, vice Hayden, resigned.

Births, Marriages, and Deaths.

BIRTHS.

HOLMES.—On the 30th ult., the wife of Dr. Gordon Holmes, of Finsbury-square, E.C., of twins.

MARSH.—On the 22nd ult., at Penn-hill, Yeovil, the wife of Charles J. Marsh, M.R.C.S. &c., of a son.

PARNELL.—On the 28th ult., at Forest-hill, S.E., the wife of G. C. Parnell, Surgeon, of a daughter.

UPTON.—On the 18th ult., at Rio Lodge, Brighton, the wife of Alfred Upton, L.R.C.P.Lond., M.R.C.S., of a daughter.

MARRIAGES.

BROWN—MURRAY.—On the 24th ult., at St. Mary's, Hulme, Manchester, J. Macdonald Brown, F.R.C.S.Eng., of Edinburgh, to Caroline Helen, third daughter of the late Alderman Adam Murray, J.P., of Apsley House, Ardwick, Manchester.

MORTON—BARRON.—On the 25th ult., at St. Pancras Church, by the Rev. Andrew Welch, Vicar of St. Mary Cray, Kent, uncle of the bridegroom, assisted by the Rev. W. E. Oliver, LL.D., Shadforth Morton, M.D., of Wellesley-villas, Croydon, son of the late Shadforth Giles Morton, Esq., of Sunderland, to E'la May, eldest daughter of Edward Jackson Barron, F.S.A., of Endsleigh-street, Tavistock-square, and of Lincoln's-inn-fields.

SHERBURN—BAILEY.—On the 25th ult., at St. James's Church, Hull, by the Rev. A. Boyd Carpenter, M.A., Vicar, assisted by the Rev. W. J. Mallish, M.A., Rector of Winestead, Holderness, John Sherburn, M.B., C.M. Edin., of Hull, to Louisa Ainley, youngest daughter of the late Wm. Bailey, J.P., of Winestead Hall, steamship owner.

DEATHS.

BEACH.—On the 29th ult., at Maryville, St. George's-road, Cheltenham, Henry John Beach, Brigade Surgeon, Her Majesty's Indian Army, retired, in his 52nd year.

CORY.—On the 25th ult., at West-mall, Clifton, very suddenly, William Gillett Cory, B.A., M.D., aged 57.

DONOVAN.—On the 1st ult., at Marine Villa, Monkstown, co. Cork, Mary Jane, beloved wife of Dr. Denis D. Donovan, of King-street, Cork. R.I.P.

JACKSON.—On the 24th ult., at Longsight, Manchester, Francis Edward Jackson, M.D., late Colonial Surgeon, Straits Settlements, aged 32.

MASH.—On the 27th ult., at St. Giles's-square, Northampton, James Mash, F.R.C.S., aged 87.

ROE.—On the 28th ult., at his residence, Kensington-crescent, W., Edward Thomas Roe, M.D., aged 64.

WILLIAMS.—On the 25th ult., at Mold, by an accident on the railway, Thomas Williams, L.R.C.P.Ed., L.F.P.S.Glas.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

"WHAT IS A MINIM?"

ON this question *Nelson B. de S. Sizer*, B.Sc., M.D., &c., of Brooklyn, N.Y., U.S.A., writes:—"The weights and measures of the United States Pharmacopœia are founded on the troy ounce of 480 grains and the wine gallon. The pint is taken as weighing 7291·2 grains at 60° F. (Pereira's Mat. Med., Am. Ed., 1866). The pound is troy, containing 5760 grains, the ounce 480 grains. From these data it follows that the fluid ounce equals one-sixteenth of 7291·2 grains, or 455·7 grains; the fluid drachm weighs one-eighth of 455·7 grains, or 56·96 grains; the minim weighs one-sixtieth of 56·96 grains, or 0·949 grain. *En résumé*—The B.P. minim equals 0·91 grain troy; the U.S.P. minim equals 0·949 grain troy; the B.P. minim equals 0·96 minim U.S.; the U.S. minim equals 1·04 minim B.P. Lieut.-Col. Herschel will now perceive that the maker of his minim glass was not guilty of a 'systematic blunder' when he sent out a sixty-minim measure that contained about 54·6 grains troy, which was just what it should hold, and that the blundering, if any, must be looked for elsewhere."

Enquirens.—1. (*a*) Yes, in some cases. (*b*) An article by Dr. F. T. Roberts in the July number of the *Liverpool Medico-Chirurgical Quarterly Journal*.—2. Dr. Alexander's paper in *Brain*, vol. v., p. 170.

Nemo.—In Reynolds' System of Medicine.

TYPHOID FEVER ON BOARD SHIP FROM IMPURE WATER.

To the Editor of THE LANCET.

SIR,—Such outbreaks of fever on board ship as the one reported from Newcastle in your issue of the 20th ult. as having occurred on a Norwegian vessel used to be frequent enough in ships of all nations. The case of a ship that has put to sea with contaminated water for her only supply is terrible indeed; and the subject is sufficiently important to warrant attention being directed through your columns to one ready resource actually at hand on board British vessels to meet this emergency. In the Scale of Medical Stores the Board of Trade orders a bottle of Condy's fluid to be carried in the medicine chest of every merchant ship, and the simple addition of this to water contaminated with organic matter, as is well known, will render it safe for drinking. No simpler, more rapid, or more economical process can be imagined in such a case than the mere pouring of a little of Condy's fluid into the water in a tank and stirring it. When sufficient has been added to neutralise the impurities, the pink tint no longer vanishes, but maintains itself permanently, thereby affording a valuable indication that the water is then safe to drink. Ship surgeons would be conferring a benefit on masters and officers by informing them of this easy way of dealing with impure water when no other is available.

I am, Sir, yours obediently,

J. B. MITCHELL, M.D.

Titchfield-terrace, Regent's-park, Oct. 1st, 1884.

Digitized by Google

Dr. James Alexander.—A certificate of having passed any of the preliminary examinations approved by the General Medical Council will be accepted by the College of Surgeons. A list of such examinations was omitted from our Students' Number from want of space, but may be obtained at the office of the Council, Oxford street.

J. Brund.—Ross's Diseases of the Nervous System will give the information.

ANILINE DYES.

To the Editor of THE LANCET.

SIR,—In your issue of Sept. 20th (page 510) I read an article respecting "Antiseptic Colours," which I was astonished to find in a scientific journal like THE LANCET. I have been in the industry of aniline colours for the last fifteen years, and therefore consider myself entitled to speak from experience. Not a single case has been brought to my knowledge which really proved that disease was caused, or any person was in any way injured, by wearing garments dyed with aniline colours. It is true that physicians frequently declare, and newspapers report on such authorities, that red hat-linings, red stockings, or blue drawers have originated serious maladies; but never has such an assertion been proved by sound arguments. You will admit that if the aniline colour did really injure the skin or the health in any way the workmen employed in our industry ought to be the first to fall victims to its influence; for not only are their garments penetrated with the dye, but their faces, hands, and arms are covered with it. They inhale the dust, and swallow the dye. Well, among about 4000 workmen employed in our own works and in the aniline colour works of our neighbours (at Mannheim, Höchst, Offenbach, Biebrich, and Griesheim) the general state of health is at least as good as that of the workmen of any other industry. The premium for insuring our workpeople against sickness is not higher than the average; and those who have been employed at our works since 1869, when we began making aniline colours, are fresh and healthy. I may add that repeatedly experiments have been made by feeding animals with aniline colours, especially with the much-calumniated magenta, and that it has been proved to demonstration that no harm whatever resulted therefrom. This is what I have to state respecting the effect of the aniline colours themselves—that is to say, the aniline colours not fixed on textile fabrics. As to the means of fixation, everyone knows that for wool and silk in most cases no mordant at all is required, and that the mordants used for cotton dyeing generally are tannic acid or sulphate of alumina, which certainly do not injure the skin even in the free state. If you compare with these harmless fixing means the ancient colours—for instance, cochineal, which is always fixed with a tin salt—you will allow that garments dyed with aniline colours must be considered at least as healthy as those dyed in the ancient manner. I have never deemed it necessary to refute the sensational accounts against the use of aniline colours as long as they appeared in common-place expressions of superficial newspaper reports; but I thought that if a journal of influence and authority like THE LANCET published an article like the one alluded to, its effect ought to be paralysed by an answer based upon the most incontestable facts.

I am, Sir, yours truly,

FRITZ GANS

Frankfurt, Sept. 26th, 1884. (of the firm of Leopold Cassella & Co.).

*** Instances of the production of a rash on the skin by wearing garments dyed with aniline colours have been observed by numerous physicians; the occurrence of such cases is beyond doubt. Mr. Gans's favourable experience may be perhaps due to the fact that our aniline contains arsenic acid, whilst his is pure. The matter, however, deserves investigation.—ED. L.

Insanity.—There is a sufficient account (for the examination mentioned) in Bristowe, last edition.

Surgical Instrument Enquirer.—The address mentioned is no doubt sufficient.

SCHOOL VENTILATION.

To the Editor of THE LANCET.

SIR,—This is a subject of growing interest, and I am glad to see it taken up by THE LANCET. I have gone into schoolrooms in which children were pent, and was glad enough to get back again into the open air. It is surely a good subject for investigation, as to how carbonic acid in different degrees affects the system; and Celsus mentions it. Not only is it important that schools which all the members of the rising generation are compelled to attend should be well ventilated, but that coal-mines should also be purified to a much greater extent than they are. In the leading article of the *Engineer Review* of Sept. 20th the writer, unable in consequence of the presence of CO_2 to light his lamp, went on working in the dark.—Yours truly,

Sept. 29th, 1884. CHAS. BROOM.

PIN-SWALLOWING.

To the Editor of THE LANCET.

SIR,—On Monday morning, about 8 o'clock, Mr. R—— came to me, stating that his boy, seven years of age, had just swallowed a pin. I recommended him to give the child plenty of bulky food, such as would tend to keep the bowels somewhat inactive, and carefully to avoid any aperient; also to search each motion for the pin. He followed this plan, and the pin, an inch and a quarter in length, was passed in a mass of fæces at 7 o'clock on the following Thursday morning.

I am, Sir, yours truly,

South Kensington, Sept. 13th, 1884. J. W.

"MODEL" BOOTS AND SHOES.

A GRATIFYING feature of the recent public awakening to the importance of hygiene generally is the increased attention which is being given to the question of the proper clothing of the feet. It is possible nowadays to meet with people who know how to protect their feet from cold and damp and rough roads without subjecting themselves to one of the most dreaded tortures of the Inquisition. In the case of children—if they are to be saved from corns and bunions, which form a life-long trouble to the majority of the members of all civilised communities—it is of especial moment that there should be some approach to harmony between the delicate anatomy of the chief organ of progression and the shape and size of the boot which is intended to cover it. These remarks have been suggested by the receipt from Messrs. Cook and Townshend, of Byrom-street, Liverpool, of a specimen of their "Child's Model Boot," which appears to fulfil the conditions necessary to ensure perfect ease and comfort in walking and running. The material is of the most pliable leather, and the shape conforms to the natural outline of the foot. By the way, we would express our preference, except in bad weather, for the shoe, as compared with the boot, for young people, as the former, by allowing easy play of the ankle-joint, permits of greater freedom of action, and favours a more lithesome motion and a more graceful carriage than can be secured with the use of the boot.

Mr. Reynolds (Castle Donington).—The proof arrived too late for corrections to be made.

"HOUSE DRAINS: A SUGGESTION."

To the Editor of THE LANCET.

SIR,—With deference allow me to question the opinion (if I understand it rightly) expressed in one of your leading articles last week *re* house-drainage. You there deprecate ground-level ventilation, and advocate a single air-shaft immediately from the house drain. I venture to doubt whether this is sufficient or sound advice. I would insist, in the first place, on distinct isolation of the house drain from the sewer by one of the many traps (their name is legion—Buchan's or Heffyer's, &c.), in which the pressure of sewer gas on the water seal, at its distal end, is taken off by a ventilating shaft near it, and carried up above the roof of the house. The shaft might be black, and as much exposed to the sun as possible. In the second place, on the proximate side of the trap I would place a good-sized ground-level grating and charcoal tray, establishing a free current of air through the drain from this point to the top of the soil-pipe ventilating shaft; all this on the house side of the intercepting trap. This part of the drain, with adequate water service, if properly laid and gradationed, would be at all times comparatively pure, while the increased pressure of the atmosphere on the low-level grating would, with what builders call "the suck of the house," tend for good in establishing the circulation of fresh air through that section of the drain immediately connected with the house.

I am, Sir, your obedient servant,

H. D. FOWLER,

Bedford, Sept. 29th, 1884. Deputy Surgeon General (h.p.).

*** If our correspondent will look again at our article, he will see that we insist as strongly as it is possible to insist on the necessity of complete "disconnection." This can only be secured by the use of a perfect disconnecting chamber. We are, however, quite as strong in our denunciation of low level ventilators, of whatsoever kind. It is all nonsense to suppose fresh air enters without the escape of impure air; the inlet pipe must come down from the roof level. Then if, as so often happens, the current be reversed, there is no harm done. As a matter of fact, if the grating over a ground-level "inlet" be tested, it will be found to be more frequently an *outlet*.—ED. L.

Dr. T. P. A. Stuart (Sydney).—The evidence before us is insufficient to enable us to express a definite opinion on the matter.

J. H. B.—We believe the test-papers are trustworthy.

G. A.—Yes.

"'HIGH' GAME."

To the Editor of THE LANCET.

SIR,—Amongst the annotations in your last issue was one on the wilful destruction of "high" game (which no doubt often unnecessarily takes place), suggesting a remedy for its correction and further preservation. Allow me to suggest another, which would, I think, be found more efficacious and easy of application—viz., to paint the tainted parts, usually the neck and chest, with a strong solution of iodine in rectified spirit, which quickly permeates the soft tissue, or any part that may be torn. It must be very "high," indeed, if this fails at once and completely to remove all taint, the solution being so volatile that not an atom, or taste, or colour of the iodine remains after cooking. On several occasions game sent me from a distance has been pronounced hopeless by the cook; but after having been dressed as above and cooked has been considered delicious, those partaking of it having no idea of its having ever been thought "high." I have also given the direction to many others, who have invariably been satisfied with the results.

I am, Sir, yours truly.

Kingston-on-Thames, Sept. 30th, 1884. GEO. MUNDIE.

Digitized by Google

Mr. Whitworth should consult a respectable medical agent. The case should admit of easy adjustment, and our correspondent's services seem to have been such as to constitute an important element in any terms to be accepted.

PROLAPSED UTERUS.

To the Editor of THE LANCET.

SIR,—An account of the following case may be of interest to some of your readers.

On July 8th I was summoned to attend Mrs. P—— in her second confinement. On arrival I found the uterus completely prolapsed, the os and cervix being external to the vulva, and forming a tumour as large as a good-sized fist. I was told that during her first pregnancy her womb had come down, but had gone up again at the time of quickening, and that she had gone to the full time comfortably. Soon after leaving her bed, however, the uterus again descended, and remained so, although she expected that as soon as she "felt life" it would rise to its proper position, as it had done before. I may state that her first child is now five years of age, and that she has never had any treatment for her trouble. On further examination I found that the liquor amnii had escaped; the os was soft and dilatable, although as thick as two fingers, the head well down in the pelvis in the first position, and the pains regular, but with little expulsive power. I administered a few doses of ergot, and gently dilated the os with the fingers; but as the pains did not improve I proceeded to deliver with the forceps, introducing them carefully through the os, and into the cavity of the uterus. On applying traction I had a great deal of difficulty in preventing the uterus being expelled *in toto*; but by grasping the cervix with the left hand, or, rather, hooking my fingers over the edge of the os, and holding it back while I extracted the head with the right, I finally succeeded, with only a slight laceration of the cervix, in delivering the patient of a well-nourished male child at full time. Immediately after delivery I restored the uterus to its proper position, and kept the patient in bed for three weeks. As soon as the lochia had ceased I commenced Dr. R. Bell's treatment by medicated tampons. This has done a great deal of good by keeping the wound in position and reducing the size and weight of the cervix; but I fear it will not be sufficient to cure the tendency to prolapse in this case, as the ligaments must be severely strained by the long-continued displacement of the gravid uterus. I find that the tampon "loses its grip," as Dr. Bell says, about sixty hours after introduction, and slips down; so now I put in a small plug of cotton, and then introduce an ordinary circular boxwood pessary. This plan answers well, so that I have to see the patient and change the plug every fourth day only.

I think this case is remarkable, first on account of the comparatively slight amount of inconvenience caused by so severe a displacement, the patient having done all her own housework and washing during the pregnancy without having made any very great complaints of suffering; and, secondly, on account of the fact that although during the whole time the fœtal head must have occupied the cavity of the pelvis the woman did not miscarry, or even prematurely give birth to the infant; she, in fact, even states she is quite sure she was pregnant almost ten months, and from the appearance of the fœtus I should say that it is at least fully developed. In conclusion, I may remark that it was rather a novel experience for me to watch the progress of what is usually the first stage of labour after the head was fully expelled from the vulva.

I am, Sir, yours faithfully,

THOS. LEAHY, M.B.Dub.

Ashburton, Canterbury, New Zealand, Aug. 15th, 1884.

FERMENTATION AND INOCULATION.

To the Editor of THE LANCET.

SIR,—Brewer's wort, in that it is an organic liquid with saline constituents and able to support at the expense of some of these organic and saline constituents different types of low animal or vegetable life, may be roughly compared to human blood. When, as in the ordinary process of brewing, the wort is inoculated with yeast, that yeast feeds on certain organic and saline bodies in the wort, reproduces itself, runs a regular course, and in due time stops feeding and reproducing, and throws itself out of the wort. The liquid left behind, beer, is devoid of these bodies necessary to support the life and reproduction of yeast. If more yeast be put into the beer, no such action as previously described takes place; the beer remains practically unaltered. But if the beer be inoculated with one of the other ferments known to it—say, with the acetic acid germ or putrid germ of the brewer—that ferment will go on reproducing until it has exhausted all its particular food that it can find in the beer; it then becomes inert, and resigns possession of the liquid. If another dose of the same ferment be then introduced into the beer, it will not reproduce itself; but the beer remains practically unaltered.

Is it not probable that when the blood is inoculated—say as a protection against some disease (e.g., small-pox)—an analogous process goes on? Some sort of ferment which requires as its food the identical bodies in the blood which the small-pox germ also requires is introduced into the blood; it feeds on and reproduces itself on these bodies until it has exhausted them; it then throws itself clear of the blood, and no ferment requiring these same bodies in the blood for its support, can live in that blood until the last has replenished itself with them. This would, I suppose, occur in time with the blood of a living being, and then the person would be liable to again "take" if revaccinated, or if not vaccinated, to support the small-pox germ—i.e., to contract the disease.

I am, Sir, yours obediently,

Kilburn Brewery, N.W., Sept. 16th, 1884. H. G. ADDIS.

MEDICAL EDUCATION IN JAPAN.

FROM a pamphlet entitled General Outlines of Education in Japan, which has been specially prepared for the International Health Exhibition, it appears that there is only one university, called Tôkiô Daigaku, which is under the control of the Department of Education. Attached to the University there is Yobimon (preparatory department) of the Tôkiô Daigaku, which consists of two schools—viz., the principal school, which is situated within the departments of law, science, and literature, and the branch school, which is situated within the department of medicine, and intended to prepare students on such subjects as are necessary for entering this department. The length of the course of study is four years in the branch school. In the department of medicine there is a course of instruction in medicine and pharmacy, and a special course is also provided. The object of the course in medicine is to train students for the degree of Igakushi, and the length of the course of study is five years; but the object of the special course in medicine is to train students as practical physicians, and the length of the course of study is four years. The course of study in pharmacy occupies three years. In the professional schools of medicine, which are situated in various localities, the length of the course of study is four years for physicians who pursue the regular course of study, and three years for those who desire to complete their study in a short time.

An Anxious Husband had better be guided by the advice of the medical attendant in the case.

A Constant Subscriber has not enclosed his card.

AN APPEAL TO PUBLIC VACCINATORS.

To the Editor of THE LANCET.

SIR,—I appear to have alarmed one of our district lady visitors, who has written to one of my guardians complaining of the manner in which I do my public vaccination—i.e., that I produce six vesicles. The instructions issued by the Local Government Board direct us to make "not less than four good-sized vesicles." Now, I am in the habit of making six small places, and am convinced that I cause no more local irritation than when I made four larger vesicles, as I used to do formerly. I have been public vaccinator here for five years, and during that time I have twice received the Government grant, and shall be much surprised if I fail to obtain it the next time the Government inspector pays me a visit. I shall esteem it a great favour if public vaccinators who read this will kindly send me a post-card stating the size and number of their vesicles, as I am requested to obtain this information; and if I get a good number of replies I will forward the result to THE LANCET.—I am, Sir, yours obediently,

Walthamstow, Oct. 1st, 1884. THOS. SCORESBY-JACKSON, M.D.

"A NEW TRACHEOTOMY TUBE."

To the Editor of THE LANCET.

SIR,—In your impression of the 27th ult. we notice, under the heading of "New Inventions," a description of a new tracheotomy tube, made in gum elastic at the suggestion of Mr. A. Rea Edwards, L.R.C.P. We beg to inform you that we have for some considerable time made them in this material, and have supplied them to many eminent members of the profession, who have used and approved highly of them. Upon reference to our illustrated catalogue, published in June, 1883, p. 157, fig. 460, will be found illustrated and described the elastic gum tubes made by us in four sizes, with or without an aperture in the tube. In consequence of the shield of our instruments being of one continuous web, it is impossible for them to become detached, and the shield, being soft, adapts itself with much comfort.

We are, Sir, your obedient servants,

New Bond-street, Oct. 1st, 1884. C. WRIGHT & Co.

"WANTED, A DIAGNOSIS."

To the Editor of THE LANCET.

SIR,—The letter under the above heading in your issue of Sept. 20th calls to my memory the following case of lead-poisoning.

A gentleman, aged fifty, presented an increasing muscular weakness of both hands, most marked in the right one. One of the many doctors he consulted thought it might have been occasioned by a long-standing habit of taking snuff which had been kept wrapped up in lead-foil instead of tin-foil, as usual in Italy. Perfect cure following the giving up of such a way of keeping snuff proved, *ex juvantibus*, the diagnosis to be correct.

I am, Sir, yours truly,

Verona, Sept. 24th, 1884. L. C.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—I shall be obliged by your allowing me to state that the inverted commas in the last paragraph but one in my communication of last week should be at the end of that paragraph, and not after the word "day," all the words being Sir Benjamin Brodie's, written some thirty or forty years ago.

I am, Sir, yours truly,

Savile-row, Oct. 1st, 1884. CHARLES HAWKINS.

ERRATUM.—In the report of the case of sunstroke at the Radcliffe Infirmary last week, the respirations were, by a typographical error, put at 136, instead of 36.

Medical Diary for the ensuing Week.

Monday, October 6.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

Tuesday, October 7.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Wednesday, October 8.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays, at 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1½ P.M.—Skin Department: 9.30 A.M., on Tuesdays and Fridays.
ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
HUNTERIAN SOCIETY.—7.30 P.M. Meeting of Council. 8 P.M. Dr. Robert Fowler: Presidential Address.—Mr. Walter Fowler: Specimens of the Bacillus Anthracis.—Dr. Pitt: Anthrax (with specimens).
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shewn by Dr. Potter and others. Mr. Hopkins Watters: Post-partum Avulsion of the Uterus, Right Ovary, and Fallopian Tube; recovery.—Dr. Horrocks: Rupture of the Uterus and Vagina.—Dr. Potter: Retained Product of Conception.

Thursday, October 9.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.
NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

Friday, October 10.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.
CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Hadden: Certain Nerve Symptoms in Rheumatic Affections.—Mr. Croft: Preputial Calculi.—Dr. Crocker: Urticaria Pigmentosa or Xanthelasmoides.—Dr. Finlay: Perforation of the Vermiform Appendix.—Mr. Golding Bird: Dislocation of the Patella.

Saturday, October 11.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year..... £1 12 6 | Six Months..... £0 16 3
TO CHINA AND INDIA..... One Year 1 16 10.
TO THE COLONIES AND UNITED STATES .. Ditto 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

Introductory Address

DELIVERED AT

ST. GEORGE'S HOSPITAL,

On October 1st, 1884,

BY F. H. CHAMPNEYS, M.A., M.B. OXON., F.R.C.P.,
ASSISTANT OBSTETRIC PHYSICIAN TO THE HOSPITAL.

THE FABLE OF THE COCKCHAFERS AND THE PIN.

ON a certain day in the fall of the year the cockchafers were wont to assemble from all parts, and solemnly to impale upon a pin one of their number, choosing each year the next younger in succession (τὸν ἀεὶ νεώτερον). The chafer, thus impaled, buzzed round upon his pin; the greater his pain, the quicker he moved his wings, and the shriller and the louder were his buzzings. At the end of an hour he was taken off his pin (for he did not always die), and all the assembly feasted together. They pledged the recent victim in nectar, and declared each year that the buzzings were superior to the last—that is, that their "tone" was "higher." At length one of the insects, whose turn to be impaled was approaching, appealed for protection to those who had but recently been tortured; but they said, "Is it likely that we, who have already undergone our torture, should endeavour to make your lot better than ours has been?" The chafer then turned to the elders and implored them to abolish the cruel and useless custom, or, if not, to give an example to the younger by themselves willingly undergoing the ceremony, which their venerable and exalted position in the tribe would enable them to endure with a dignity unattainable by comparatively mere grubs. To him they answered: "We should have much pleasure, but our time for buzzing is past; moreover, each must have his turn; whatever has been must be; and do not you perceive that no sooner is each chafer taken from his pin than he becomes an upholder of this ancient custom?" Moral: Expect no relief of suffering in the future from those who have suffered in the past.

The fable which I have just read to you, gentlemen, has of course nothing to do with the present occasion, but, as a graduate of a "lost medical school," I have thought it not inappropriate to bring before your notice a "lost fable of Æsop," which, so far as I can ascertain, has never been hitherto translated into English.

The first part of my task consists in the pleasant duty of wishing you all a happy new medical year, and in expressing the hope that this year each of us may do his very best—whether teacher or pupil—to add to the honour and credit of St. George's Hospital. We have received great and honourable traditions, and it rests with us to add to them or to diminish them. The first cannot be accomplished without enterprise and without self-denial; the second will occur without any effort on our part—it merely requires the very common qualities of supineness and procrastination, and the result is assured. But I think I may venture to speak for all, and to say that no effort shall be wanting on the part of old or young (for we are all students to the end of our days) to do the very best in our power to uphold the honour of our school. To those who make their first appearance to-day I would give a special word of welcome, and I can tell them from personal experience that not many days will elapse before they will feel as if they had been at St. George's all their life. This result is partly due to the friendly relations between teachers and taught, which are, I think, one of the traditions of the place, and it is partly due to the moderate size of our school, which renders personal attention far more possible than in larger institutions. Among their fellow-students they are sure to find pleasant companions and plenty of such amusements as are not incompatible with—or rather, I should say, are aids to—work. The great thing is to make a good start. About this I shall say more later on.

The year that has just passed has deprived us of two members of our consulting staff, Dr. Barclay and Mr. Cæsar Hawkins. Dr. Barclay had so lately left the active service of the hospital, that he was known in that capacity to most of us as a kind, courteous, and comely gentleman of a school which is becoming scarce—of a school which studied prognosis before all things, and whose prognosis, often arrived at by different methods from those most relied on by their successors, was not seldom surprisingly correct. Our modern engines of precision, the stethoscope and thermometer, are invaluable, but while we have gained much from their use, we have almost certainly lost a little in the way of a general study of the aspect of the various forms of disease. This power in practitioners of the old school was greatly developed in proportion as it was one of their chief means of diagnosis, and therefore of treatment.

Dr. Barclay was of course well acquainted with all modern methods, but he had had the advantage of the old ones also. To the modern student the order of importance would, I suppose, seem to be (1) treatment, (2) diagnosis, and prognosis would come a "bad third" or "nowhere;" but its place is far higher, for in one view it accurately follows diagnosis, and in another it may be studied even apart from this, and in cases where diagnosis is highly uncertain, or even impossible; in any case it completes and rounds off the study of the natural history of disease, and, so to say, "proves" the sum set us to solve. Dr. Barclay added several valuable treatises on various subjects to medical literature, but it is to be regretted that a man whose mind was so cultivated, and whose education was so varied, did not accomplish even more than this. The reason is perhaps to be sought in his health, which had been for some time far from robust, or in natural temperament, which was the reverse of sanguine. His death at the last was sudden, and, to those who had seen him not many hours earlier at the College of Physicians, apparently in his usual health, unexpected. We miss the refined face and presence so long familiar to St. George's Hospital.

In Mr. Cæsar Hawkins St. George's has lost an important link with its past history. He had long ceased to have an active concern in our medical school, but was not unfrequently to be seen at meetings, and his face was familiar to most of us. His connexion with St. George's Hospital dates as far back as the year 1819, in which he entered as a student to the lectures of Mr. (afterwards Sir Benjamin) Brodie, and to those of Mr. (afterwards Sir Charles) Bell. He was intimately associated with the work of these eminent men, as well as with that of Sir Everard Home, Herbert Mayo, and others. He held in turn every office at the Royal College of Surgeons, and nearly every post open elsewhere to a surgeon, amongst others that of Serjeant-Surgeon to the Queen, being the fourth of his family to hold that office. As a surgeon I am told he was conservative in principle, but intrepid in action when necessity arose. His literary contributions were privately published ten years ago in two volumes, and are a collection of very great value, showing their author as a highly cultivated medical man. About his character there is but one opinion, and that is that he was a man of noble mind, whose strength of will and tenacity of purpose were only equalled by his sincerity and unselfishness. It is, perhaps, owing to the absence of self-seeking, which was one of his characteristics, that he died undecorated, except by the judgment of the highest court of appeal, that of his peers. Individually I regret much that my connexion with St. George's commenced too late for any personal acquaintance with him, for example is better than precept, and men such as he is described to have been are not met with every day; indeed, I would say happy is the man who has been admitted to the intimate friendship of one such person. To all of us he should be an example of uprightness and honour in a profession where such virtues are paramount, and are far more important in every sense than learning, or skill, or success. Indeed, the most chivalrous and scrupulous honour is not always the surest means to success.

Our teaching staff has been augmented by Dr. Delépine, a gentleman whose high scientific attainments will doubtless bear fruit in our medical school.

Some of us have to-day begun their connexion with the medical profession, which they have selected, or which has been selected for them, for very various reasons. A certain proportion are the sons of medical men, and naturally look to joining their fathers sooner or later. It is true, however, that the life of hard work and few relaxations often acts as a deterrent, and that the medical calling is the last chosen by those who have witnessed such a life in their fathers' houses.

Digitized by Google

This is perhaps just as well, for our profession is not one which will satisfy those who seek for *otium cum dignitate*, nor do we want such men in our ranks. Others, again, have a hankering after the military or naval services, but having been unable to persuade their friends to allow them to enter a profession in which they will practically have to pay to be allowed to work, they join our ranks in the hope of some day healing the injuries which it was their earliest ambition to cause. Others, again, choose the medical profession because they "must do something," and think that they will dislike this less than any other occupation. To others our profession is simply and honestly the object of their choice, and they have embraced it spontaneously and with all their heart as the occupation in which they look forward to live and die. From one class we are happily free—namely, the class which selects one or two of the other learned professions simply with the view of gaining a certain status in society, and losing the identity and surroundings of the individual under the generic term of the profession to which he belongs. Much is written from time to time as to the social status of our profession, the absence of decorations conferred upon it, and its comparatively low rank in society. With regard to the latter there is at present a Grand Duke of Austria among the members of our profession, a fact on which no doubt the profession is to be congratulated, but I think his Serene Highness still more. For we must remember that among the motives which may influence men in choosing a profession are included these two—first, the hope of being stamped or marked by the profession, and secondly, the hope of leaving their stamp or mark upon it; and in proportion as we accomplish the second, we shall help to accomplish the first both for ourselves and for others. The second of these objects depends partly on eminent skill, partly (as the world is constituted) on what is called "success," but far more on the honour and uprightness, which perhaps attain their highest development in the best (not always the decorated) members of the medical profession. It is probably a distinct loss to the State that no members of our profession are selected as the official and authorised advisers of our legislative assemblies on matters so important as health and disease, and that questions of national importance concerning these departments are more or less at the mercy of class prejudice or vulgar popular oratory, and that such influences appear at times to dominate our rulers. It seems, however, as if one or two recent fiascos of this nature were likely to bear fruit in the direction of the appointment of responsible advisers whose duty shall be to instruct our rulers on medical matters.

On the whole, then, although the chief seats in our assemblies do not yet carry with them such titles as Baron Sarcoma, Viscount Strabismus, and the Duke of Anasarca, it is probable that a learned, honourable, and chivalrous doctor is not less honoured and valued than a learned, honourable, and chivalrous lawyer or clergyman, and that these qualities do meet with recognition in the world. But, after all, recognition by the world—that is, by those least able to judge—should not be the aim of anyone embracing the medical life. Laying aside the highest appeal, to which no reference will now be made, there are two other judgment seats whose commendation we may all lawfully covet. The first is the assembly of our peers, a body acquainted with our circumstances and with the details of our calling, and capable of judging our conduct as experts. But here, again, we must distinguish between the opinion of those more and those less competent to form a correct judgment, including in the latter category a considerable number of individuals whose views are interested, or who act as the *claque* to some medical journal. There still remains another forum—namely, that at which we ourselves sit, or should sit, in judgment on ourselves. The value of this tribunal will vary according to the manner in which we have trained our conscience; but, unless we have committed the heinous crime of deceiving ourselves, we may take this as the ultimate (or rather penultimate) court of appeal. This court may acquit us when the lower courts have (perhaps justifiably) condemned us; we may have been hissed, but we may applaud ourselves, like the actress Arbuscula, who said, "Populus me sibilat, at mihi plaudo"—a sentiment which, in certain cases, is quite right (begging the poet's pardon). On the other hand, we may have been acquitted by our peers, but condemn ourselves.

In any case, we should make up our minds to act in such a way as to earn our own approval, to win (in any reasonable way) the approval of our peers, and to trouble ourselves but little beyond this. If we reverse this order we may win applause in the lowest court; but we shall jeopardise our standing in the court of our peers and shall inevitably lose our self-respect. The injury which in such a case we do is not confined to ourselves; it degrades our whole profession, while the opposite course elevates it. Our profession, if used merely as a means to wealth and success, is a very low one; while on the other hand, success of the highest kind and competence, at the least, do, as a fact, usually accrue to those who seek first the unselfish honour of their calling. As a money-making concern medicine is certainly a relatively poor speculation, compared, at least, with business or with some other of the learned professions, and large fortunes made nominally by medicine are often, in fact, the result of a nucleus judiciously manipulated in the neighbourhood of Capel-court, and cannot be taken as representing real professional work. Money so acquired may be made the means of other forms of success and advancement. But this kind of business cannot be considered as part of our calling, however lawful it may be, and, generally speaking, competence rather than wealth is the financial termination of our lives. Still, it is generally true that "He that will work, likewise shall he eat." It speaks volumes for the interest and attractiveness of the profession that our ranks are constantly swelling, and swelling with men whose education and social status appear to improve every year in spite of the fact that its members are comparatively poor. There is, indeed, a means by which a large practice is sometimes made and a considerable fortune realised—namely, by a system of advertisement, more or less cleverly veiled, or not veiled at all. Those who pursue such a system sell their birthright for a mess of pottage, and in some cases make an excellent bargain, for they exchange a doubtful reputation for actual wealth, and are very satisfied with the transaction. It is sad when the exchange is made by those whose birthright is really worth something. With regard to this I would only say that we are not tradesmen; and if we practise a trade under the disguise of a profession, we cannot claim to rank even as honest tradesmen—we are trading under false colours. It rests with us, in this instance, again to remember the honour of our calling, not only by avoiding such doings ourselves, but by taking care that, as far as we are able, they shall not pay where others practise them. No single person in this theatre is devoid of some influence, and our influence will continually increase; let us see that it is used on the right side. It is not enough to encourage the good and to leave the contrary alone; if we do, the others will have the better; for they encourage themselves in mischief and actively oppose the contrary. Our influence therefore must be exerted both in the way of approval and disapproval. I must warn you, however, that honesty is not always pecuniarily the best policy, and it is certainly not a short cut to wealth. There are three things, it has been said, which a poor man cannot afford to keep: Pride, a Horse, and a Conscience. All undoubtedly involve an outlay, or, in other words, a loss of money; but it is to be hoped that all here will never part with the first and third, and will acquire the second as soon as they require and can afford it, though not before.

Having thus made up our minds that our ambition is not the acquisition of wealth, but the pursuit of an engrossing study, which our lives will be all too short to complete, and in which we can fairly expect to combine the most absorbing scientific interest with the satisfaction of feeling that as citizens we are discharging duties of the very highest importance to our fellow-men and to the State, by which we may live but for which we can never be repaid, let us next see how we can best fit ourselves for these duties.

The first thing for those who have just joined us is to lose no time in setting to work. "Well begun is half done" is a proverb so true that it exists in two ancient and at least three modern languages. Besides, they can have no idea how much they will have to learn, nor how short the time is in which they are expected to learn it; but those who have finished, or are just finishing, their studies, will tell them that, in order to omit nothing, it will be necessary for them to make the very most of their time. Time requires no killing in London; he commits suicide. They must remember, too, that they will be required to have all the knowledge asked for at their fingers' ends, and all the subjects ready at the same time. To most persons it is a necessity to learn things more than once, and it is not until they have learnt them—and forgotten them—a few times that they begin to remember them. The examiner will not accept the excuse that we knew the answer to his question once any more than

Digitized by Google

the mistress of the household accepts the phrase that "the water has boiled" as an excuse for weak tea; to make good tea, the kettle must be "on the boil," as the saying is, and so must we to pass our examinations. It is only familiarity with our subject which will breed contempt of the examiner—or rather, I should say, of the examination. I would personally advise you to pay particular attention to the curriculum as set forth in the calendar, and to take each course in its proper order; if you procrastinate and put off this, that, or the other to the "more convenient season," you will probably find that the ground is already occupied by some other study, and you will lose one or the other. The curriculum is the result of much careful thought, and has been modified from time to time with a view to its improvement. It is not the result of arbitrary or casual dictation, and is meant to lead rather than to drive. I advise you therefore to follow its directions.

The first work which you will be given to do is to study the bones—a very dry study you will think; but it is one which must be mastered, and thoroughly mastered. Its object is at least twofold: first, to educate your powers of observation; secondly, to teach you the most important facts of the structure of the body. The first will seem to you quite simple until you begin it, you may even despise and be disposed to neglect it. I advise you to do nothing of the kind. The powers of observation which you bring to bear on a dry bone need developing, and you will find that the same powers will enable you to make a good diagnosis at the bedside, and your value as a practitioner will largely depend upon the degree to which you possess them. Most persons require to learn to "see with their eyes, to hear with their ears, and to understand with their heart," and you must make it a matter of conscience never to say you feel or see or hear anything unless you really do. To do so is to speak "the thing which is not,"—to tell a lie. The verification of the absence of one sign is as important as that of the presence of another and requires far higher education. Those of you who love natural objects, and who have been used to watch and study animals and plants and the sky in country life will probably find less difficulty in mastering a bone than others; but powers of observation, however acquired, will certainly stand you in good stead. I think some difficulty is often felt just here by those whose minds for instance have been dealing with quite a different order of facts, although their education has been superior. In an ordinary university education our reasoning powers are cultivated rather than our powers of observation. Our reasoning powers and power of working with method thus acquired will certainly stand us in good stead, and with more benefit the further we advance, but at the start we must learn to educate our senses. This comparative power of observation is easily recognised when we refer to the arts. We stand, perhaps, on a hill side by side with a painter: the same image is painted on the retina of the eye of both of us, but let each of us say what he sees, and the artist sees a thousand times as much as we do, for "seeing, we saw, and did not perceive," while he saw—and perceived. After he has pointed out to us what there is to see, we perceive it too. Or let us hear music side by side with a musician; we hear perhaps the most prominent melody and nothing more. If the music consists of many strains, none of them overpoweringly prominent, we say we hear no tune but a noise. But let our companion point out to us the "motives" of which the music is composed, we direct our attention to more than one, by degrees and by practise we gain the power of listening to all. Besides this, no doubt practice actually renders our senses acuter. All these principles enter into your first study, that of the bones.

Besides the education of our powers of observation this study also forms the backbone of our whole knowledge of anatomy; the relations of the skeleton to the various organs are such that they constantly involve the knowledge of nerves, arteries, and muscles, together with the bones. If you wish to find your anatomy easy to learn and easy to remember, know your bones accurately, nay pedantically. Dissection will educate your hands as well as your powers of observation; its chief object is, of course, to teach you the topography of the country, every inch of which ought to be known. The method of dissection will be taught you when the time comes; but I would here generally caution you that the object is not to cut *away* every part as soon as you have seen it, but to expose region after region, and layer after layer, in order to view each in turn and to learn them. You have *not* thoroughly learnt them until you can shut your eyes and see everything in your dissection in its proper order and relations, and draw them, however roughly. Your day's work is not to be measured by the depth to which you have penetrated nor by the destruction which you have wrought. Such an ambition is praiseworthy in a miner, but is not so in a dissector. The same conscientious method applied to physiology, and to your other early studies, will stand you in invaluable stead throughout your career. I purposely avoid saying how much time and how much attention you should bestow on anatomy and physiology respectively. If a man intends to be a locomotive engineer it is obviously necessary for him to know the structure of his machine and its working also. If it is necessary for him to know every rod, bolt, and nut, and to be acquainted with the properties of the metal of which each is made, he must also have a thorough knowledge of the laws regulating the combustion of fuel and the expansion of steam. Knowledge of structure and knowledge of function are both of paramount importance, and, as we we are not now settling what should be so much as what is demanded, comparisons are (surely) odious. I advise you to follow the curriculum and pay your very best attention to both. Here, perhaps, it will be as well to issue a caution against premature specialisation—against any specialisation, that is, which precedes a thorough general medical education. I think that microscopy is sometimes a snare in this way, so seductive is it, so beautiful are the objects we see by its means, that a man is liable to stop short at whittling and staining, and to forget that the whittling and staining are only humble means towards the great end of studying the tissues, healthy and morbid. He may find that others have passed him by, and that the knowledge of health and disease (of physiology and pathology) which they have gained in the course of their ordinary studies has not only enabled them to pass their examinations, but to understand the preparations that he makes even better than he does himself. This is the "microscopical man." Far removed from him, but more dangerous, is the "practical man." This person is probably rarer than formerly; his ambition is to do something to patients, generally in a surgical direction. He is not conservative in this department, and longs to remove as much of his fellow-creatures as he is allowed, or at least to produce as much alteration in their appearance as possible. On the medical side, his assaults are carried on by means of drugs, the more powerful the better. With this end in view, he despises and neglects all the preliminary studies of anatomy, physiology, auscultation, and percussion, and gets to treatment as soon as possible. He obstructs the wards and out-patients' rooms in his first session, being quite unable to understand or profit by what he sees. The preliminary part of any course of lectures in any department of medicine or surgery, which are the foundation of all that will follow, he also despises, while he may perhaps condescend to make a note on a shirt sleeve or cigarette paper, of a drug or an operation. The results are surprising in examination, and resemble an old patchwork quilt, with many a "hiatus valde deflendus." At the bedside he is "all there" in one sense and "nowhere" in another, and happy is he if he finds before he is a responsible medical practitioner that the knowledge of the course of a nerve, of the relations of one of the viscera, or of one of the simple facts in obstetric anatomy or physiology, is among the number of things which it is sometimes as well to know for the diagnosis of a disease or for the treatment of a patient.

So closely allied to the "practical man," that he may be regarded as a variety, is the man whose ambition it is to pass his examinations with the least available knowledge and the least possible trouble. His horizon is bounded by the "First College," and he disdains any information which he thinks will not be required for this ordeal. He is even angry with an instructor or lecturer who wastes his (the student's) time by endeavouring to impart any knowledge which interests him (the teacher), and is correspondingly (though but moderately) grateful for a bit of "cram" or a "tip." Such a piece of information, and such alone, will draw a note-book (if he has one) or the back of a letter from his pocket. It is even amusing to the teacher to forecast this display of energy. Of such "tips" he makes the most astounding use in examinations, since they comprise nearly all he knows, and he never understands their meaning. When questioned on the subject he quotes the name of his teacher to the examiner. Examiners are generally alive to the state of affairs, and the "things that should

Digitized by Google

have been to his health are unto him an occasion of falling." Quite rightly too, for a man who gains his knowledge in this way is unfit to enter our profession. Let us make up our minds to it, knowledge will not come to us without an effort; it may come to the windows of our mind, like the dove to the ark, but we must reach out our hand and pull it in or it will fly away again. It will not again come in through the pores of our skin, even if we live in an atmosphere of information; and yet, were we living in a more transcendental era than the end of the nineteenth century, I should feel inclined to discuss the question whether in order to acquire knowledge it is not necessary to expose our hands to the air, at any rate I have observed an inability to absorb it on the part of those who attend classes and clinical instruction with their hands in their trousers' pockets.

I must next caution you against a weakness which is sometimes found among those whose ambition it is to appear to possess knowledge without the trouble of acquiring it. These are not often really clever persons, but frequently possess the power of smattering and imposing on their more laborious fellow students. Their great art is to conceal ignorance in a cloud of verbiage. They are fortunate if they only impose on the more simple-minded of their fellow-students, who may be heard to remark: "What a lot Garrulus seems to know, and he says he never reads!" fortunate if Garrulus himself is not included in the ranks of the deceived. His deception, however, generally ends here, for he is better adapted for spontaneous display than for withstanding the assaults of the examiner, or even of any fairly informed person, whose first questions generally have the effect of depriving him of his lion's skin and discovering beneath it—well, just *Garrulus*.

This ambition, the ambition of appearing a *roi fainéant*, is really most contemptible. Do-nothing he may be, king of men he never will be; and, indeed, how high in the animal creation are we to place one who does nothing? I am principally annoyed with him because he lords it over and terrifies many a modest and hard-working student who is not ashamed of working. Besides, he sometimes does grind very hard when he thinks no one will know, though principally with the unprofitable object of displaying his cleverness when an opportunity offers. However, he generally gets his deserts. Let us, then, not specialise too early; let us not be ashamed to work hard; let us not neglect what seem to us humble facts. The contempt for little things has been happily represented in the poem of the "Haughty Actor" [which the lecturer then read].

With a view to work, a certain amount of play will be necessary. We do not want to be "dull boys," but we must not be "idle boys." In choosing the nature and amount of our play, we must remember that we are no longer at school; that we are engaged in studies on which the whole success of our life, and even the lives of others, depend; and that all play must be regarded as a means to work. Among games which can be thoroughly recommended is football—a game which necessitates regular habits if it is to be played well, and which has the additional advantage of promoting our *esprit de corps*. The success which our comparatively small school has achieved in the football field, and the fact that some of our best players have been also among the number of our best students, speak so strongly that I need only remind you that football is not included in the subjects on which you will be examined; and that you must see that it conduces to your work. I know from personal experience that the most violent and exciting exercise need not take an hour away from the available working day. Some other amusements have to be regarded with suspicion. The worship of Terpsichore, though I have known it lead to the most interesting and happy results, is not generally conducive to work. I had far rather enunciate principles than details, but unless you can be at your work at 9 A.M. the next morning, and do as good a day's work as ever, or unless you confine your dancing to Saturdays, I advise you to regard it with caution. Some of you may think that you owe a duty to society in this respect. I advise you to remain in her debt. She will endeavour to console herself in your absence, and will not press for payment. Nay, the members of which she is composed would far rather imagine you at work with a view to their own benefit than even enjoy your company. Indeed, I would throw out as a hint for your consideration that it is just possible that the very persons who enter your name on their list of dances may at the same time enter your name at least on the tablets of their mind as a person *not* to be entrusted with the care of their health. The great temptation to idleness begins in the first summer session, when the sight of the park, teeming with the life of "the season," is apt to make us forget the seriousness of our work, and to deposit us, dressed in the latest fashion, in the cheap but luxurious depths of a penny chair opposite the Row. Pennies soon mount up, and so does the score of missed lectures and demonstrations. But we are not yet hopelessly lost, our Alma Mater has her eye on us, and while we have been slaying—or missing—our coveys of Tetraonidæ, she has, with motherly hand, been forging for us a crook (the head of which is already finished, and only needs the attachment or "adhesion" of the "staff") with which our hind leg is gently seized, and we are drawn again into the fold, so gently that but for the fear of causing *her* distress we should, no doubt, promptly repeat the experiment. On the head of the crook are engraved the letters "D.C." But, really, at St. George's Hospital we have unusual inducements to work; I doubt whether at any other medical school so many and so constantly recurring encouragements to industry are offered in the shape of prizes at every step of our career. If we have not the *vis a tergo* to which we were used at school, we cannot complain of the absence of a *vis a fronte*. Let us then make a good start and keep up the pace, with the motto, "Occupet extremum scabies."

I should not feel that I had discharged my duty did I not devote a few words to the department of work to which I am more particularly attached. And, first, I would remind you all that the various licensing bodies having a short time ago succeeded in grasping the fact in elementary statics that a body propped on two legs is almost necessarily in a state of "unstable equilibrium" have added to the two previous legs of medicine and surgery the third leg of midwifery. The result is on one hand a great addition to the stability of medical education, which is now a triped; but from your point of view it amounts to the fact that it is now practically impossible to gain possession of any respectable diploma without the acquisition of a tolerable knowledge of midwifery and the diseases of women. Whatever your line of practice may hereafter be you cannot avoid it, and in the words of the immortal showman, "You can't go in without paying, but you can pay without going in; I can say no fairer nor that." Nor, indeed, is it fair that any practitioner should be ignorant of either of these subjects, neglect of which is apt to be followed by grotesque and egregious blunders, which may prove disastrous to him who makes them. In general practice you will find that this knowledge almost more than any other other will stand you in good stead, and early in your career you may have cause to bless the nights which you spent, perhaps unwillingly, surrounded m y be by squalor, alcohol, and the Heteropters. As a subject for instruction I know none which surpasses midwifery; its problems are largely exact, involving as they do mechanical principles which can be actually demonstrated by diagrams and models; and in practice diagnosis and prognosis are quickly illustrated by the event. The nine months' cycle of pregnancy carries us into one of the most interesting regions, in which physiology is so modified as to border on, and therefore to illustrate, pathology; while in embryology (with part of which we necessarily deal) we are brought face to face with the most vitally interesting speculations. In the sub-department of the diseases of women our interests are different; this is still in its infancy and the greatest discoveries lie almost beneath our eyes, it we could only see. This subject, the paramount interest of which lies with the investigator, appeals to us therefore in a different way.

As a moral training and as a training for practice, midwifery seems to me again most valuable. The student or the practitioner is brought into close and intimate relation with his patient, and he learns to be patient with her, not to be brusque with her but considerate, even to endure reproaches, unjustly uttered, during paroxysms of agony, knowing that

> A patient in pain
> Is a patient insane—

to be patient too in waiting. No sooner will his patient be rid of her troubles than her gratitude will make up, and more than make up, for any inconsiderate utterances. And here I must testify to the patience and kindness of students—often the last to lay claim to these or indeed to any other virtues—which has repeatedly instructed me. Not once or

Digitized by Google

twice have I known the fire lit, food bought and cooked, and the tenderest care displayed in the maternity department by students to those from whom they had nothing in the world to expect. In the course of your practice you will probably have to treat some of the poorest, and you may have to treat some of the highest. You may think it will be difficult to be ready with the appropriate manners for each. Not at all. It would of course be an error to treat a duchess like a charwoman, but there can be no harm in treating every charwoman like a duchess, and you will be right all round. To be a good practitioner you must also have "clean hands (antiseptically as well as ethically) and a pure heart," and, while recognising the fact that Nature generally manages her own affairs best in her own way, and that your duty in most cases is to watch how she does it, you must be minutely acquainted with her ways or you will not detect the first beginnings of mischief, and will not be prepared to help her when she is untrue to herself. For this reason the study of the normal anatomy and physiology of pregnancy, labour, and lying-in is of paramount importance, and cannot be too conscientiously pursued; indeed, without this your understanding of abnormal conditions and processes will necessarily be lamentably inadequate. For learning the principles of midwifery you have ample opportunities, and I advise you (as the very easiest way of learning them) to attend your lectures diligently and to take notes, copying the diagrams, schedules, and classifications which are written up for you. Moreover, I recommend you to attend the course at least twice: once in your second summer, when you will be introduced to the subject with little or no trouble to yourselves, and once as your final examinations approach, and you are able, having gained a fair knowledge of the principles of medicine and surgery, to appreciate their application to obstetrics.

Besides this, there are the classes in practical midwifery, specially intended for those about to be examined, which are going on throughout the medical year; and altogether I think that the students of St. George's have only themselves to thank if they fail to pass their examinations in this subject, or if they find themselves in practice without a fair knowledge of this branch of their profession—a misfortune to which failure in examinations is not to be compared. One other reason I would give for diligence in studying obstetrics, and that is the good of your teachers. None but teachers know the stimulating effect of an intelligent and attentive class, and especially of a class which take notes. I am, myself, constantly reminded of the passage in "La Grande Duchesse," where Fritz, having been degraded from the rank of field-marshal to that of a common soldier, is finally turned out of the army altogether. The Duchess asks him what he intends to do, he says to keep a village school. "Mais (says she) sais-tu lire?" "Non (says he), c'est pour apprendre!"

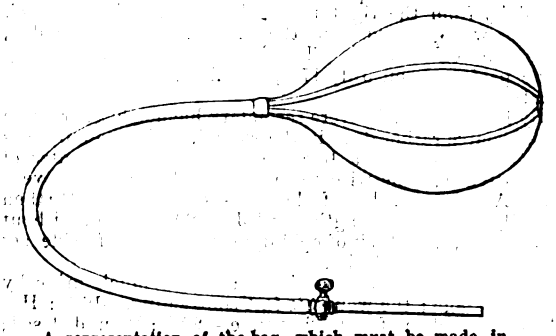
Have this consideration then for your teachers, and do what you can to instruct them.

Three stages may be described in the life of an orator, the stage of terror at his own voice, the stage of indifference, and the stage of self-admiration, in which the sound of his voice becomes pleasant to its owner. Any stage may be suppressed or may be indefinitely prolonged. Secondly, what is true of his life as a whole may be true of every speech. Thirdly, the converse is generally true as regards his audience. To apply this to the present occasion, I have long passed the first stage, and am conscious that I am rapidly approaching the third, but mindful that the converse is liable to be true as regards my audience, and also that I have now buzzed round upon my pin for forty-five minutes, I ask you kindly to dismount me in order that we may prepare to fulfil the second and more agreeable part of the ceremony.

BEQUESTS.—The late Mr. William James Patterson bequeathed £5000, free of duty, to the executive body of the Royal South Hants Infirmary, to be called "The Patterson Chaplain Fund," upon trust, for investment, the income to be appropriated as a stipend for a chaplain; £1000 to the Royal South Hants Infirmary for its general purposes; £500 to the Southampton Dispensary and Humane Institution; £250 each to the Royal Hospital for Incurables, Putney, and the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury; and £150 to St. Mary's Cottage Hospital, Southampton.

A CASE OF

SUPRA-PUBIC OPERATION (PETERSEN'S METHOD) FOR LARGE STONE IN THE BLADDER.



BY SIR H. THOMPSON, F.R.C.S.,

SURGEON EXTRAORDINARY TO H. M. THE KING OF THE BELGIANS, PROFESSOR OF SURGERY AND PATHOLOGY TO THE ROYAL COLLEGE OF SURGEONS, CONSULTING SURGEON TO UNIVERSITY COLLEGE HOSPITAL, ETC.

AT the close of my final lecture at the Royal College of Surgeons in June last, I stated that I had successfully dealt with uric-acid calculi up to three ounces in weight, by means of lithotrity at a single sitting, although I by no means asserted that all such calculi were amenable to the crushing operation. And after discussing the methods which might be resorted to when, owing to the size of the calculus, lithotrity was inadequate or unadvisable, I stated that, for my own part, "I should almost certainly submit the next case for which the knife is required to the high operation with Petersen's modification."

Not a week had elapsed from the date of that observation before the following case presented itself; and I think it will appear to be one of sufficient interest and importance to merit a brief report in the pages of THE LANCET.

A gentleman aged thirty-six, formerly under the care of my friend, Dr. William Roberts of Manchester, who had observed continuous and large deposits of cystine in the

A representation of the bag, which must be made in separate gores of stiff white indiarubber to ensure firmness. A soft collapsible bag does not accomplish the purpose required.

urine for some time, came to me with severe symptoms of calculus in the bladder on June 18th last. On sounding, I immediately struck a large stone, and advised lithotrity without delay.

June 19th.—I attempted under ether to seize a large, hard, and rather rounded mass, but it escaped the grasp of my largest lithotrite. Dr. Caspar of Berlin and Dr. Pinter of Buda Pesth were present. After devoting three or four minutes to the careful examination of the calculus, both by the bladder and rectum, I determined to wait a day or two, and then to perform the supra-pubic operation. The patient had fever after this, which was unusually prolonged, and nearly a fortnight elapsed before I considered him in a fit state for operation.

July 2nd.—Mr. Moss gave ether; the gentlemen above named were present. I commenced by injecting about nine or ten ounces of a weak solution of boracic acid in water into the bladder, and tying the penis firmly with a vulcanised catheter, I then introduced the pear-shaped india-rubber bag (see fig.), folded longitudinally, into the rectum, distending it gradually with water from a large syringe until about twelve ounces had entered, when the stopcock was turned. On percussing the lower part of the abdomen, it was obvious that the bladder was now occupying the supra-pubic region, a rounded mass corresponding thereto being very clearly defined. I made the usual longitudinal incision about three or three inches and a half long in the median line, the lowest point of it reaching to the front aspect of the upper margin of the symphysis, carrying the dissection through the soft tissues down to the linea alba; then dividing on a director that structure itself, also the fibrous attachments of the recti muscles to the symphysis for nearly half an inch laterally

Digitized by Google

on each side of the opening. The yellow fat covering the bladder then came into view, and this I divided solely with the index-finger and forceps. Scraping in a direction upwards with the nail of my right index-finger, and hooking up all the tissues therewith into the upper angle of the wound, it was easy to verify beneath my finger the distended bladder, the surface of which had thus been cleared. No artery had been divided, and a vein or two in the fat had been drawn aside, so that, contrary to what is usually met with in elderly patients, in whom the veins here are often large and liable to cause considerable difficulty by free hæmorrhage, almost no blood had been seen. Inserting a well-curved hook into the bladder, and thus giving issue to a little of the injected solution, I incised its coats sufficiently to admit my finger, when I felt lying there directly beneath it a large calculus, the position of which was, topographically considered, abdominal, and not pelvic. It was now a simple matter to enlarge the incision and remove the stone with a pair of small forceps and my finger, my friend, Mr. G. B. Browne, taking care to maintain the sides of the bladder in place by hook and spatula. I then untied the ligature on the penis and allowed the urine to flow from the rectal bag, inserting a No. 12 gum catheter and fastening it in the urethra, after which I placed a large vulcanised tube five inches long (with a single lateral aperture only, close to the terminal one) deep in the bladder, so as to ensure free drainage, and removed the bag from the rectum, completing the proceeding.

I laid the patient on his side, well supporting him in that position by numerous pillows at his back and between the legs. For I think this position an important element in the after-treatment, since it facilitates the drainage and enables the attendants to keep him dry. He should be changed once daily from the right to the left side, and *vice versâ*. The tube was removed from the bladder on the fifth day, the catheter on the sixth. The first urine passed naturally by the penis was on July 17th, the fifteenth day after the operation.

July 19th.—He had severe secondary hæmorrhage from an arterial source rather deep in the wound, which happily was efficiently stopped by a ligature within a few minutes of the occurrence; otherwise the result might have been very grave. As it was, the loss of blood was considerable. He then gradually regained strength until July 29th, when, without known cause, an attack of epididymitis in the left side set in, and again reduced him.

Aug. 8th.—He begins to sit up; passes much urine by natural passage; the wound is fast contracting.—16th: Has walked out of doors for the first time.—20th: Wound closed; holds urine three hours; appetite good; recovering strength fast; returned home on the 24th, and bore his journey to the north well.

The calculus proved to be cystic oxide throughout, was of a rounded oval form, and weighed two ounces and three-quarters.

I heard in September from Dr. Roberts that he had seen the patient, that his condition was quite satisfactory, and that no cystine was at present observable in his urine.

I shall make no remarks here on the history and nature of the operation, having given a short *résumé* of these in the lectures delivered in the Royal College of Surgeons last summer, now just published. Nor is it necessary to add anything respecting the mode of performing it, as I have been careful to point out all the important practical details necessary to be attended to in describing the procedure above. I shall merely add that having performed the suprapubic operation by the old method, on the staff, and without preliminary injection of the bladder and rectum, I have no hesitation in regarding the method here described as greatly superior, contributing as it does in no small degree to the safety of the peritoneum, as well as to the ease with which the stone is extracted.

Wimpole-street, W.

THE WATER-SUPPLY OF CROCKHAM-HILL.—On the 27th ult. a preliminary meeting of some of the residents of Crockham-hill was held to discuss the best measures to be adopted in order to procure an adequate supply of water for the village. It was stated that during the recent summer water was sold continuously in Crockham-street at the rate of one shilling for six gallons, and the villagers have had to buy it at that rate when their supply of rain water was exhausted or go without entirely. A subscription list was started to raise the necessary funds, and a considerable sum has been already promised.

ALLEGED EMIGRATION OF WHITE BLOOD-CORPUSCLES FROM THE INTERIOR OF SMALL VESSELS BY BORING THROUGH THEIR WALLS.

A REMONSTRANCE.

BY T. WHARTON JONES, F.R.C.S., F.R.S.

THIS remonstrance is addressed to professors of physiology and pathology against teaching in their writings, lectures, or occasional orations, that the white corpuscles of the blood escape from the interior of small vessels, until they have verified it scientifically by actual observations of their own as a fact in Nature. We are told that on the establishment of vascular congestion in a part, white corpuscles of the blood escape from the interior of capillaries and small veins, by boring through their walls, and that supervening on this emigration of white corpuscles, such red ones as had become aggregated and stagnant in capillaries are squeezed out through pores in the walls of these vessels by the force of the stream of blood from behind. That white corpuscles of the blood escape from the interior of small vessels is a fancy which first arose from mistaking the nuclei embedded in the walls of capillaries for white corpuscles in the act of boring through. In Plate 4 of my Essay in Guy's Hospital Reports for October, 1850, such nuclei are exactly represented, as seen under a quarter of an inch object glass;—some being nearer the inner surface of the wall, as if commencing to bore through; others more towards the outer surface, as if they had nearly bored through. As to the squeezing out of the red corpuscles, stagnant in capillaries, by the force of the stream of blood from behind, this allegation is utterly contrary to what can be easily seen—viz., that at the commencement of resolution, the said corpuscles are gradually driven on by *vis a tergo* into the venous radicles, until the congestion by stasis is dissipated and the circulation in the part re-established. Extravasation of blood does indeed sometimes occur, but this is owing to rupture of small vessels. In cases of catarrhal ophthalmia, for instance, ecchymosis of the conjunctiva is not uncommon, but does not form any part of the inflammatory process. Even when there is no inflammation, ecchymosis, it is well known, sometimes occurs.

In No. 35 of the *British and Foreign Medical Review*, published about forty years ago, I particularly insisted on the fact that at the commencement of inflammation of the cornea vascular congestion presents itself in the adjacent part of the conjunctiva and sclerotica, though not in the cornea itself, this structure being normally non-vascular. From the fact that at the commencement of keratitis there is no vascular congestion in the cornea (the vessels seen pervading its substance in an advanced stage being of new formation) Professor Virchow started the doctrine that inflammation has no necessary connexion with vascular congestion, but is in its essential nature a process of "proliferation," by which he meant an abnormal degree of cell-development in the affected part. Herein was overlooked the congestion of the vessels in the adjacent part of the white of the eye, from the blood circulating in which, in the normal state, the cornea derives its nourishment, and from which in the inflamed state the materials for "proliferation" would be derived. When the cornea is injured by incision, abrasion, or cauterisation, vascular congestion in the adjacent part of the white of the eye is excited by reflex nervous action from the nerves irritated by the injury of the cornea to the vaso-constrictor nerves of the small arteries of the adjacent part of the conjunctiva and sclerotica. In idiopathic keratitis congestion in the adjacent part of the white of the eye takes place in a similar manner in consequence of the irritation which the nerves in the cornea suffer from being involved in the commencing intrinsic morbid action.

Virchow's paradoxical announcement that inflammation is not inflammation at all according to the old definition, but merely a process of "proliferation," found great acceptance among those who are always on the look-out for some sensational novelty. "Rubor, calor, tumor, et dolor" were accordingly turned out of doors, and "proliferatio" entertained instead as the true "claimant" to be the characteristic of inflammation. Ere long, however, "proliferatio"

Digitized by Google

was in its turn discredited. In 1867 the late Professor Cohnheim came to the front, teaching that the cells supposed by Virchow to be the produce of proliferation are in reality the white corpuscles of the blood, which, as we have seen, he alleges to escape from the interior of small vessels by boring through their walls, and that this "emigratio" of white blood-corpuscles constitutes the essential part of the inflammatory process.

Before examining further the doctrine that white corpuscles make their way from the interior of capillaries and small veins by boring through their walls, I beg to refer to the series of three papers "On the Blood-Corpuscle," published in the Philosophical Transactions for 1846, in which I described and delineated the changes of shape which the white corpuscles are seen to undergo in blood immediately that it is drawn from the living body. Many years after this an announcement of these amœba-like changes of the white corpuscles came from Germany as a "new discovery," and was ignorantly received as such in this country with great *éclat*. On this "new discovery" Cohnheim founded his doctrine that by means of the processes which they shoot out in all directions, the white corpuscles bore their way out from the interior of small vessels.

On an injury of the cornea by an abrasion, a cut, or cauterisation with a point of nitrate of silver, vascular congestion in the adjacent part of the conjunctiva and sclerotica, it is above said, quickly supervenes. This congestion, it is generally taught, is owing to a supposed primary active dilatation of the calibre of small arteries, permitting of an increased afflux of blood in the capillaries and venous radicles. According to my contention, however, it takes place in consequence of an impediment to the full stream of blood in the small arteries from constriction of their calibre (owing to contraction of their muscular walls excited by reflex action, propagated from the injured nerves of the cornea to the vaso-constrictor nerves), whereby aggregation of the red corpuscle in the capillaries and venous radicles is permitted, with stasis sanguinis as the result; the congestion being thus by accumulation from retention of blood-corpuscles, not by increased afflux of blood. But let that pass for the present. From the interior of the capillaries and venous radicles in the congested part, white corpuscles, according to Cohnheim, escape by boring through the vascular walls by means of the processes they shoot out, and then, by the same means, make their way into the interstices of the corneal substance to become pus cells.

It being impossible to examine the inflamed eye in a living frog under a sufficiently high magnifying power, all that Cohnheim and his followers have thus asserted as to the emigration of white corpuscles from the congested vessels into the corneal substance must be pronounced merely imaginary, a substitution of subjective excogitation for objective demonstration. As to Cohnheim's account of the microscopical appearances of detached portions of the corneal structure, it is equally inconclusive in a scientific point of view, because the histological elements being dead or moribund, have already undergone deviations from the appearance proper to them in the living state. With regard to the white corpuscles, the fact is that they do not shoot out processes while the blood is still within the living vessels. In the blood circulating in the lungs of the frog, as I long ago showed, and also of the newt, as I subsequently found, the white corpuscles are, indeed, less round and distended looking than in the vessels of the web, and present a somewhat collapsed aspect, but do not shoot out processes. The red corpuscles, on the other hand, appear in the vessels of the lungs somewhat more distended, soft, and flexible than they do in the vessels of the web; in which respects they resemble the red corpuscles of inflammatory blood, being like them also pale in tint.[1]

It is only in blood drawn from the vessels, as I showed in my papers in the Philosophical Transactions for 1846, before referred to, that white corpuscles undergo change of shape by shooting out processes. As the form they thus assume is more or less stellate, it need scarcely be added, therefore, that even if the white corpuscles still within living vessels did shoot out processes, the stellate form thus acquired would effectually interfere with their escape by any boring action. Many years before Professor Cohnheim promulgated the doctrine that an essential part of the inflammatory process is the escape of blood-corpuscles from the vessels which are the seat of the congestion, it had been, as mentioned above, alleged that white corpuscles may be seen in the act of boring through the walls of capillaries. A late eminent professor, who affected to be an authority on questions physiological, although he did not always think it fit in the original itself to look or even to read what had been recorded by those who had thought it fit to do so, on hearing of Cohnheim's sensational doctrine, claimed priority in the discovery for a friend of his, one of the able observers, who thus mistook the nuclei embedded in the walls of those vessels for white corpuscles in the act of emigrating. In the course of my prolonged investigation of the mechanism of the circulation in the extreme vessels and on the state of the blood and the bloodvessels in inflammation, made nearly forty years ago, my attention was constantly directed to see whether any escape of white corpuscles could be observed to take place from the interior of vessels. And again, when Cohnheim's allegations were published, I made a new and special investigation of the point; but I never could discover blood-corpuscles, white or red, escaping from the interior of small vessels—arteries, capillaries, or venous radicles. In my essay on the state of the blood and the bloodvessels in Inflammation,[2] the following observations are, however, recorded:—"In an intensely inflamed web of a frog the veins were very much dilated, and their walls sometimes no longer distinguishable. Forming the sides of such venous channels numerous colourless corpuscles were seen accumulated, whilst the blood flowed freely in the middle." "In a case in which the second web had sloughed away to a small piece, stagnation of blood still existed at the edge of that piece, but higher up a free flow of blood had now superseded stagnation. Here the walls of many of the vessels can no longer be distinguished, and the blood appears to be flowing in mere passages hollowed out in the substance of the web. All along the sides of the passages numerous blood-corpuscles are adherent. The adherent corpuscles are many of them red, but most of these red ones, again, are round."

If, in the figure given by Rindfleisch, a follower of Cohnheim, purporting to represent white corpuscles, escaped and escaping from a vein in an inflamed part, the indication of walls had been omitted, there would have been some resemblance to the reality, as was described by me. In such English manuals of physiology and pathology as have come under my notice, I have found along with imperfect and inaccurate accounts of the mechanism of the circulation in the extreme vessels, the emigration of white corpuscles from the interior of small vessels asserted as a well-established fact. In one book it is stated that white corpuscles may be seen to escape from the interior of bloodvessels and to enter lymphatics. In none of the works referred to, however, have I been able to recognise any indication that the accounts given had been drawn up by the authors from direct observations of their own. One professor, in his popular Manual of Physiology, vaguely says: "It is known that white corpuscles escape from the interior of small vessels."

Desirous of learning anything that might have escaped my notice on the point, I have asked professors of note for information as to their experience of the matter. Some could not give me any confirmatory answer, though they did not venture to question Cohnheim's assertions on account of the reputation of himself and his followers. At last I found two professors who seemed to consider themselves competent to afford me the desired instruction. One of these gentlemen assured me that he was as certain that white corpuscles bore through the walls of capillaries and small veins as he was of his own existence, and to confirm his assertion forthwith made a diagram of the alleged phenomenon. In this diagram, however, I recognised a representation merely of the nucleus in the wall of a capillary vessel such as I delineated with great accuracy in Plate 4 of my essay in Guy's Hospital Reports for October, 1850, about twenty years before the occurrence of the incident I speak of. But, letting that pass, the gentleman undertook, at my request, to demonstrate the actual fact, and politely invited me to visit his laboratory for the purpose. Here he displayed the mesentery of a frog under the microscope, and, bidding me look, left me. I looked and

[1] In my observations on some points in the anatomy, physiology, and pathology of the blood in the *British and Foreign Medical Review* for 1842, I recorded the fact that in a mixture of blood and pus the red corpuscles are observed to be so soft and yielding as to admit of being drawn out into mere filaments in passing through narrow spaces between the pus cells, and yet, when free, to resume their original form.

[2] Guy's Hospital Reports for October, 1850, p. 51.

Digitized by Google

saw, as I had seen before in my own microscopical examinations of the mesentery of the frog, displayed, I venture to say, in a far more efficient manner for accurate observation, numerous white cells on the surface, but which were merely the cells of the peritoneal secretion, and not escaped white corpuscles of the blood at all. In my own careful researches undertaken for the purpose of satisfying myself of the truth, I never did detect the slightest indication of an escape of white corpuscles from any of the mesenteric venous trunks returning from the capillary system of the frog's intestine. Of course there could be none from mesenteric capillaries or venous radicles, seeing that there are no such vessels in the frog—the only vessels in the mesentery of that animal being arteries going to and veins returning from the capillary system of the intestine, with here and there arterioles which I discovered opening directly into venous trunks, but which were mistaken by the late distinguished professor, Theodore Schwann, for capillaries with muscular walls.[3] Capillaries, he forgot, do not open into venous trunks, but only into venous radicles. The gentleman who displayed the mesentery of the frog under the microscope for my inspection, it should be mentioned, laboured, like Cohnheim himself, under the mistaken impression that there are capillary vessels and venous radicles in the frog's mesentery. From the other gentleman whom I asked if he had ever really seen white corpuscles of the blood escaping from the interior of capillaries or venous radicles by boring through their walls, I received the most confident assurance that he had. "Will you demonstrate the fact to me," I then said. "Oh, yes," he patronisingly rejoined, and invited me to his laboratory for the purpose. I accordingly presented myself there at the appointed time. He, however, did not present himself, but delegated a student to meet me, who displayed the tongue of a frog under the microscope, and bade me look. In the same professor's syllabus of lectures I have since found the following statement:—"When a tissue is injured, the capillaries begin first to widen and then to leak, the plasma and leucocytes passing out in succession, and that more intense injury produces stasis and extravasation of coloured discs." Did the professor mean that this should be accepted as an observation of his own from Nature, or merely as an enunciation of Cohnheim's doctrine improved in its terms for the benefit of his students? I long ago showed, both by verbal description and pictorial delineation, that by pressing with a blunt point over an artery or a vein in the web of a frog's foot (1850) or a bat's wing (1852), so as to cause contusion of the inner layer of the wall of the vessel, a greyish granular floccule composed of white corpuscles held together by a viscid fibrinous-looking substance is deposited, filling the calibre of the vessel partially or completely.[4] Here, notwithstanding the injury of the tissue, no emigration of white corpuscles was seen to take place through the contused walls of the vessel. As little even have I observed any special tendency of white corpuscles to escape from the mouths of small divided vessels. The white corpuscles accumulated in the plasma of an internal clot remain within the truncated end of the divided vessel, though, according to the emigration doctrine, they might easily work their way out from the gaping orifice, through the collection of red corpuscles and fibrin forming the external clot.

In conclusion, now, let it be said: 1. That as yet no accurate and consistent observation has been adduced to prove decidedly that white corpuscles of the blood emigrate from the interior of small vessels by boring through their entire walls under any circumstances, physiological or pathological. 2. That when white corpuscles are found unenclosed in a vascular wall, this is because the wall has disappeared from having become disintegrated and dissolved, as I showed thirty-five years ago. The blunder that nuclei in the walls of capillaries are white corpuscles in the act of boring their way out, no one I presume would, like the gentlemen before referred to, now venture to uphold—not even that professor who was "as sure of it as of his own existence."

Ventnor, Isle of Wight.

[3] Malpighi examined microscopically the vessels of the frog's mesentery, but made out nothing similar to what he discovered in the lungs.

[4] At the British Medical Association meeting at Belfast, a professor of physiology, in an oration, referred to this fact, but in such a way as to show that he had never "thought it fit on the original itself to look," or even to send the original record of my observation, which he attributed to another observer who first learned the fact from a study of my essay, and who only noticed the fact in a writing published long after.

CLINICAL NOTES ON A CASE OF SANGUINEOUS CYST OF THE ABDOMEN.

By THOMAS OLIVER, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE INFIRMARY, NEWCASTLE-UPON-TYNE, AND LECTURER ON PRACTICAL PHYSIOLOGY, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

In the month of May of last year a young woman, aged twenty-four years, a widow, was admitted into the Newcastle-upon-Tyne Infirmary complaining of pain in and swelling of the abdomen. The case was sent in as one of ordinary ascites. There was a large quantity of fluid in the abdomen, but it was encysted; it was entirely confined to the lower part of the left half of the abdomen. The temperature was above 100°, a fact which increased the difficulty of making a diagnosis between the disease which it afterwards turned out to be and such things as tubercular peritonitis, ovarian tumour, peritonitis, &c. There appeared in May, 1883, in THE LANCET, a paper on "Sanguineous Cysts of the Abdomen," by Dr. Bristowe, and by it much light was thrown upon a diseased condition which for long might have puzzled me.

On admission the patient's feet were swollen, her face was sallow and anæmic. She stated that she was the mother of one child, five years of age, and that since the death of her husband she had been leading the life of a prostitute. Eighteen months before coming under observation her menses ceased, and for three months prior to this she had suffered almost continually though not greatly from metrorrhagia. She had always enjoyed excellent health until the menses ceased, but it was only within the three months previous to her coming under my care that she detected the swelling of the abdomen. It had never been localised. Her attention had been drawn thereto by a feeling of constant pain confined to the lower part of the abdomen. For some time, however, before the abdomen swelled, she had suffered from frequent vomiting. Her appetite was bad. The urine was scanty and passed with difficulty. The bowels were normal. Beyond very slight prolongation of the expiratory murmur at the right apex the lungs seemed healthy. The first sound of the heart was normal, the second was accentuated. The abdomen was greatly distended; it measured at the level of the umbilicus forty inches and a quarter; fluctuation was well-marked, particularly in front and on the left side. A network of enlarged veins was seen coursing up on either side. The right flank and iliac region were tympanitic on percussion, but as the middle line of the abdomen was approached the note became duller and less tympanitic. Over the whole of the lower half of the left abdomen there was absolute dulness on percussion, and there was marked resistance to but no pain upon pressure. This dulness extended about an inch to the right of the middle line and had its upper margin two inches above the umbilicus. On placing the patient on her right side it was noticed that the left half of the abdomen remained absolutely dull on percussion and that fluctuation was well-marked. The upper part of the left flank, however, became tympanitic. No souffle was detected on auscultating this area, and on vaginal examination the os was found to be low down and gaping. The uterus was freely movable, nothing being felt either behind or in front of it. The sound passed with ease to the bend of the instrument; its direction was upwards and to the left.

Briefly, her condition on admission was as follows. A large and somewhat rounded mass was occupying the lower half of the left abdomen; it was more or less fixed, as it did not alter to any extent with change of position of the patient. It gave on tapping very distinct waves of fluctuation; physical signs which, with a history of absent menses, suggested at first ovarian disease, although the accompaniments of pain, increased temperature (on the second day after admission it was 102°), the negative results of a vaginal examination, and, the positive sign, alteration of the respiratory murmur over the right apex, rather raised the question of tubercular peritonitis. Having decided to aspirate the tumour, our junior house-surgeon, Mr. Hudson, on May 8th, inserted a small trocar and cannula into the lower part of the abdomen; 148 ounces of blood-red fluid escaped, which under the microscope was found to be composed almost entirely of

Digitized by Google

blood cells. The coloured cells were crenated. The colourless were large and exhibited amœboid movement.

In spite of the very large quantity of fluid which was removed, there was detected two days afterwards very distinct fluctuation in the left abdomen. The right half was perfectly clear and tympanitic on percussion, the left, especially in its lower half in front, was absolutely dull. Change of position did not alter the relationship of the dulness. Her urine, however, had been passed in larger quantity; it had a specific gravity of 1025, was acid, deep orange in colour, and contained a large quantity of urates, but no albumen. There was pain in the abdomen. For some days after this the temperature kept rising. By the evening of May 17th it was 104·2°. The pain in the abdomen was now severe. The physical signs already mentioned were again becoming prominent; it was evident fluid had again accumulated. On May 20th the patient was again aspirated, and eighty-four ounces of fluid similar in character to the last were removed. This time the abdomen seemed to be completely emptied, for the lower half of the left abdomen now gave on percussion a clear note. Under the microscope the fluid was found to contain myriads of crenated red discs of various sizes, a few indefinite corpuscles like ordinary lymph cells, some of which had undergone fatty granular degeneration, while in others vacuoles, could be distinctly seen.

Previous to the second operation the patient had in addition to the rise of temperature suffered from slight difficulty in breathing. On examination the lower half of the left chest was found to be absolutely dull on percussion, and over it there was noted absence of the respiratory murmur, absence of vocal resonance and fremitus, while over the upper half of the lung the breath sounds were harsh and tubular. As time went on, and the respiratory murmur returned, crepitation and friction sounds were heard. It is difficult to account for this pleurisy of the left side. Like most cases of ordinary pleurisy, it was limited to the left side. It was in the left half of the abdomem that the tumour existed, and possibly by means of the lymph canals which traverse the diaphragm material may have passed from peritoneum to pleural cavity and set up inflammation there. It was not tubercular, as the patient made a good recovery; a later examination of the chest failed to detect anything but slightly prolonged expiration at the right apex. Strange to say, however, as the effusion disappeared from the left pleura physical signs pointed to a reaccumulation of fluid in the abdomen, but this time its existence was temporary. It never called for further aspiration.

It is unnecessary to give further details of this case. Suffice it to say that by July 30th the patient had made a good recovery. Pain had disappeared; the temperature had been normal for some time; the area of dulness in the abdomen had greatly diminished; and at her own wish she left the hospital. Nine days afterwards I was asked to see her in consultation, as pain now of a very severe character had returned accompanied by vomiting. The abdomen was flat, but there was still the area of dulness in its left half, diminished in size, resistant, and semi-fluctuant. By those who saw her with me, the worst opinion possible was entertained. Permanent relief, it was thought, could only be got by removal of the cyst by abdominal section. She was readmitted into the infirmary. Opium in small quantities having been given, I applied freely fly blisters to the abdomen. In a few days pain had entirely disappeared; no complaint of it was made even on the application of deep firm pressure. The whole of the abdomen in front, left as well as right, was tympanitic. A degree of dulness lingered for a short period in the left lumbar region. Spinal tenderness in the mid-dorsal region was complained of, but it soon yielded to blistering. On vaginal examination the lips of the os uteri were found to be everted; the posterior lip was found to be retracted by means of dense bands which passed between the cervix and posterior vaginal wall, and the uterine sound passed with some difficulty just beyond one inch. After this the abdominal dulness entirely disappeared. The patient left the infirmary quite recovered. On September 19th I saw her. She was then in excellent health. She had regained flesh and colour, pain had never returned; menstruation, which had been absent for two years, had reappeared a few days previously. Concurrently with this return to health, she had resolved to abandon her former life—a resolve which I believe she has faithfully carried out. Three months afterwards I heard from her; she was then engaged as a laundry-maid in one of the retreats in the south of England, and was in the best of health. This is still maintained. In a letter which I saw from her six weeks ago she was then in excellent health.

What, then, was the nature of the cyst? Situated in the left half of the abdomen, a renal, splenic, peritoneal, and pelvic origin was each in its turn suggested. Beyond the presence of a large amount of lithates in the urine, which was passed in small quantity, there was an entire absence in it of any abnormal constituent. The tumour was too low down in the abdomen, and also too much to the front, for the kidney to be in any way connected with it. Its presence so low down and so far forward, with the absence of a well-defined margin, led me to ignore the spleen as being its origin. The after-history of the case, morning temperature frequently higher than the evening, and the fact that an intercurrent attack of pleurisy with effusion was successfully passed through, show conclusively, I think, that the case was not one of tubercular peritonitis; nor can the cyst be considered as having been malignant. I am inclined to regard the cyst as having been in some way or other connected with the left ovary; possibly it depended upon an aggravated rupture of the ovary at the time of menstruation. What lends some little support to this supposed origin are the facts of cessation of the menses, a cessation which took place long before any tumour was felt by the patient in the abdomen, and their return after the treatment adopted, a point similarly noticed in ovarian cases after successful ovariotomy. Against this view of the origin of the cyst may be urged the character of the life led by the patient, it being a well-known fact that many prostitutes do not menstruate for years. I am inclined to think this tells both ways. The intense ovarian excitement, coitus during menstruation, and the not too kind treatment to which these women are subjected, render them liable to such an accident. One of Dr. Bristowe's cases turned out post mortem to be a cysto-sarcoma growing from the pelvis. I regard the case I have quoted, however, as a hæmatocele of ovarian origin, and I am led to record it from the difficulties which surrounded its diagnosis and the success which followed a simple line of treatment—aspiration.

Newcastle-on-Tyne.

MELANCHOLIA, IN ITS RELATIONS TO DIMINUTION OF THE OXYGEN SUPPLY.

By J. HARRINGTON DOUTY,
DEPUTY SUPERINTENDENT, WORCESTER COUNTY AND CITY ASYLUMS.

AMONGST the various diseased conditions of the mind there is none which, in its special or general pathology, presents more points of interest than does melancholia. I propose to direct attention to one of these—viz., to the fact that mental depression is very frequently associated with anæmic conditions, with valvular or structural diseases of the heart, or with pulmonary lesions—in a word, with those states of the various organs or of the blood itself which result in insufficiency of the supply of oxygen by the blood to the brain. After discussing this point and referring to cases in illustration, I shall briefly consider the etiological connexion which may exist between melancholia and oxygen famine. A careful examination of a number of cases of melancholia in the Worcester Asylum has resulted in the conclusion that in a very large proportion—75 per cent.—either (1) the blood itself was impoverished—there was an anæmic state; or (2) the state of the respiratory or circulatory apparatus was such as to prevent healthy aeration. Forty-seven per cent. of the patients were anæmic. This anæmia was the result of various circumstances. In some 18 per cent. the character of the patients' daily occupation in coal mines, ironworks, needle factories, potteries, shops, &c., was responsible for the impoverishment of the blood. Where fresh air is scarce, and carbonic anhydride and organic impurities accumulate in places filled by crowds of *employés*, there are the predisposing and immediate causes of anæmia. When, too, as is often the case, after the day's work is done the employed go either to insanitary homes or to a public-house in some close alley, and spend the rest of the day in an atmosphere even worse than that which they have left, there is no chance for their blood to make up for the losses it has sustained during

Digitized by Google

the day. On admission we find patients who come from such conditions pale and feeble, with anæmic murmurs and languid bodies. Their minds are so devoid of vigour as to render them indifferent to the pleasures and occupations of life, capable only of looking upon the dark side of things in general, and even in many instances depressed to such an extent as to be tired of life itself.

In those cases where melancholia accompanies anæmia it would seem that it is usually rather the chronic form of anæmia than the acute (if I may use the term). In the chlorotic conditions of girls, which come rapidly and are so extreme as to lead the patient to notice her condition and seek advice, resulting usually in a rapid cure, the mental state, though occasionally one of depression, is generally a slight general inactivity of the functions. Melancholics admitted from places and circumstances that produce an anæmic and unhealthy condition frequently improve as by magic; they obtain an invigorating country air, are made to take plenty of healthy exercise out of doors, and lead a regular life. These things, together with hæmatinics, iron, quinine, or arsenic, and in many cases stimulants in the form of brandy, beer, ammonia, and ether work the best results. The patient improves in appearance, gains weight, gets a good colour, and in these simple cases uncomplicated by grave bodily diseases speedily recovers in respect to his mind. So much for melancholics with simple anæmia.

I will speak now of melancholics who possess grave organic lesions, producing anæmia or some other condition causing diminution of oxygen supply, and will give extracts from the notes on ten cases.

CASE 1.—H. D——, aged thirty-five, ironworker. Melancholia, suicidal tendencies; white and pasty; renal heart and pulse; hæmaturia, albuminuria; died. Microscope revealed subacute interstitial nephritis; brain not atrophied, large, and very white.

CASE 2.—D. I——, a needle-stamper, aged fifty. On admission, as still, intensely melancholic. Agitated at times and strongly suicidal. Has had for twelve years intermittent hæmaturia, worse of late, and rendering him extremely anæmic. No heredity. Urine contains large large numbers of blood-corpuscles. No vesical calculus and no other symptoms, excepting the bleeding and melancholia. Previous medical attendants report old symptoms of left renal calculus. It has been noticed that when bleeding is worse his mind is also worse. No drugs do any good excepting, to a slight extent, ergot and iron at times. He is in a critical state, which fact, with the indefiniteness of the symptoms, contra-indicates surgical interference. He needs constant watching to prevent his self-destruction. Prognosis very bad.

CASE 3.—J. W——, aged fifty-seven, moulder. Melancholia; suicidal. Was admitted immediately after an attack of acute rheumatism; has had several subacute attacks since, and has very loud, rough, apex and basic bruits; his pulse is intermitting, short, and toneless. All kinds of treatment have been tried, but without effect. Heart is worse; he is as suicidal as ever, and is thin, feeble, and intensely anæmic.

CASE 4.—S. B——, aged fifty-two, ostler. Acute melancholia; very anæmic. Had loud whistling mitral regurgitant bruit. Left lung dull everywhere. Moist râles, of a bubbling nature, over its upper half; no air entered its base. At apex cavernous breathing, whispering pectoriloquy, and metallic râles. Died. The autopsy revealed a small localised empyema at extreme right apex communicating with the lung, from which probably came some of the pus he expectorated. The left lung was in a condition of fibroid contraction, the bronchi, in the upper lobe, were greatly dilated, their mucous membrane red and covered with pus. Pleura greatly thickened. Mitral valve puckered, hard, and almost immovable.

CASE 5.—T. P——, aged fifty-eight, a newspaper correspondent. The most actively suicidal patient in the asylum. He has had several dangerous attacks of syncope since admission. His heart is large, feeble, and irregular in its action; præcordial pain, and pain down left arm; capillaries on cheeks dilated. He is very white, feeble, and breathless, and has frequent headaches and dyspnœa. Mental condition probably depends, as do his other symptoms, on fatty degeneration of the heart. He has taken iron, belladonna, digitalis, ammonia, ether, strychnia, quinine, and other tonics, and at times has a morphia hypodermic injection, or chloral and opium draught at night. The patient has slightly improved, and can now take a little out-door exercise, and do some literary work. Prognosis, however, is as bad for his mental as for his physical condition.

CASE 6.—G. W——, aged sixty-three, a carpet weaver. Acute melancholia; suicidal; refuses food, and has needed artificial feeding; very pale and thin, and has a double mitral bruit. He gets no better, but progressively worse.

CASE 7.—A female, aged fifty-six. Has all the symptoms of fatty degeneration of the heart, and her mental condition is exactly like that in Case 5, in which there is also probably a fatty heart; she is intensely anæmic, and no medical treatment has been of any avail in relieving her symptoms; she holds, amongst others, a fixed delusion that one of the night-nurses is going to "freeze her alive"; she is strongly suicidal.

CASE 8.—W. A. D——, aged thirty-two, a shopman. Melancholia; he has a purplish skin and chronic pulmonary congestion, from which he has twice nearly died, depending on mitral stenosis; his heart's systole is short and his pulse is toneless and irregular. He is becoming gradually mindless.

CASE 9.—A. G——, a female, aged fifty, dressmaker. Has chronic melancholia and fibroid phthisis.

CASE 10.—C. K——, a female, aged sixty-two. Has chronic melancholia. She is very anæmic, thin, and feeble, and has grave mitral disease.

These are a few cases. I might multiply their number almost indefinitely; they are all interesting in their special, and most of them also in their general, pathology. I have carefully reviewed during the last few months the cases of those melancholics admitted into the Worcester Asylum since 1882, with the following result. Out of the fifty-two cases admitted conditions causing the oxygen supply to be below the healthy standard existed in no less than thirty-nine. Of these thirty-nine, ten were cases of simple anæmia from unhealthy lives in insanitary conditions, &c.; eleven others had grave diseases of the heart (valvular or fatty degeneration); five had chronic affections of the lungs, and in the rest of the thirty-nine there were various causes of impoverishment of the blood, or disturbance of its circulation, such as atheroma of the vessels, renal calculus, surgical injuries, chronic alcoholism, renal disease, &c. In the rest of the fifty-two (thirteen cases) the blood, heart, and lungs were healthy or nearly so, and of these thirteen ten have recovered or are convalescing. Of the ten simple anæmics, six have recovered; of the eleven heart cases two have proved fatal, one is improved, and the eight remaining are chronic. Of the lung cases four are chronic melancholics; one has sufficiently recovered to go home. Amongst those with the less serious causes of oxygen deficiency five are recovered or convalescing. Thus out of the fifty-two cases twenty-three are well or nearly well; in five prognosis is doubtful; and in the remaining twenty-four it is bad or hopeless, on account of the serious bodily conditions which obtain. With facts like these before one it is but natural, though one may possibly have travelled along a wrong path, to arrive at a conclusion that some definite connexion exists between the "miserable" mind and an imperfect supply of oxygen to the brain. In confronting the etiology of melancholia, wrapped as it is in uncertainty and concerning which so little investigation is recorded, even circumstantial evidence which points to a theory is valuable. There is a very natural tendency to seek for its cause amongst influences which act directly upon what we call "mind." An individual's happiness depends certainly to a considerable extent upon the kind of his surroundings; upon his wealth or poverty; success or failure; upon the temperament of those who are his daily associates; upon contentment; upon the kind of part he has to play upon the world's stage. Trouble, disappointment, worry, and anxiety, long continued, may doubtless so react upon the healthiest of minds as to cause disorganisation of its functions. A sense of weariness is induced; the individual acquires a feeling of disgust with things in general, and becomes depressed and miserable. His interest in things around him gets worn out, and his thoughts turn rather to the effects which he feels these surroundings are working upon himself. From such a state, by exaggerating his troubles and his sins, by looking at everything on its dark side, he begins to draw on his imagination, and passes into a condition of insanity, conceives delusions, or meditates or commits the act of self-destruction. So by indefinite and invisible gradations is the melancholic state matured. Its production, however, by such mental influences alone is, I believe, by no means the rule; and when depending upon such alone, it generally yields

Digitized by Google

to appropriate treatment. In a very large number of cases we have no history of misfortune or monotonous anxiety to account for its origin; and in such we turn to physical conditions, and inquire whether there is not a melancholia which depends on these for its causation. That such should be the case would be no more extraordinary than that mental anxiety and worry should, as they certainly are capable of doing, produce a diarrhœa. Some cases, of course, depend largely upon hereditary predisposition to insanity. Of the fifty-two cases in question there is history of heredity in three only of the thirty-nine associated with bodily diseases; whereas of the thirteen admitted in "good bodily health" no less than eight were distinctly hereditary. In a large proportion of cases, however, we cannot point either to mental or hereditary influences; and in these what is responsible for the mental affection? As I have said, observation has led me to believe, and is daily strengthening the belief, that an imperfect oxygen supply may alone produce a melancholia. How variations in its supply to the cerebrum act in producing a predominance of happy or of miserable types of thought, I will not venture to discuss; but facts seem to suggest that they are intimately connected with such predominance. The events even of everyday life may bear this out. After a day or week of close confinement in an unhealthy chamber, resulting in a low and despending state of mind, a condition of disgust with things in general, how a walk or ride in pure air outside raises one's spirits. A man under such conditions often comes in feeling, as he says, "a different man." There has been an abundant supply of oxygen, and the exercise has stimulated his heart to increased exertions in driving the oxygen-loaded blood rapidly through his cerebral arteries. The raising of one's "spirits," the generation of happy thoughts as opposed to the miserable, which attend a journey or sojourn in a highly ozonised atmosphere, are surely physiological results; and so also the opposite tendencies of unhygienic conditions to bad temper, irritability, gloomy and miserable states of mind are pathological certainties. Such unhygienic conditions, I hold, we may associate with the various organic diseases I have above referred to and anæmia, as all tending towards the same mental state; and it seems more than likely that they exert their respective influences towards its production through "imperfect oxygen supply" as a common medium.

Worcester.

WHICH IS THE MORE FREQUENT SITUATION IN MALES OF THE INDURATED CHANCRE, INFECTING SORE, OR INITIAL SIGN OF SYPHILIS?

By FREDERICK W. LOWNDES, M.R.C.S.,
SURGEON TO THE LIVERPOOL LOCK HOSPITAL AND CONSULTING SURGEON, SEAMEN'S DISPENSARY.

SOME time ago my colleague, Dr. Bernard, called my attention to the circumstance that the indurated chancres seen by us in our male patients at the hospital and dispensary appeared to be most frequently situated upon the prepuce. Previously to this we had both been under the impression that the more usual seat was in the furrow near the frænum, on the corona glandis, or on the glans, situations where the syphilitic virus might be expected to adhere, especially in cases where the prepuce was long, and where a want of cleanliness was also co-existent. Careful observations in hospital, dispensary, and private practice confirmed Dr. Bernard's statement, and I suggested to him that we should make independent notes of all the cases which came before us until we had observed a number sufficient for statistical purposes. In the course of a few months we had records of 400 cases, made up as follows:—Lock Hospital 163; Seamen's Dispensary, 134; private practice, 103—total, 400. Every care was taken to include none except the true infectious sore. In many cases this was made manifest by the concurrence of secondary eruptions; in others the induration was well marked; while in all there was an incubation period more or less long and the presence of indurated inguinal glands, either in one or both groins. We were ably assisted in the hospital returns by Mr. T. W. Serjeant, the resident superintendent, who carefully recorded our diagnosis of each case in the "case-books." In every case which was of a doubtful character we deferred recording it until its nature had been fully established.

Before giving the results in detail, I would wish to notice the remarks and statistics of different authors with reference to the locality of chancres. Messrs. Berkeley Hill and Arthur Cooper, in the second edition of "Syphilis and Local Contagious Disorders," say (page 84): "The superficial hard ulcer or erosion is the most common form of initial lesion. A favourite locality for it is the inner surface of the foreskin." At page 87 Mr. Hill says: "Of 150 cases seen by himself at the Lock Hospital in 1861 there were 41 initial lesions of the furrow, 31 of the inner prepuce, 24 of the outer prepuce, 17 of the frænum, 15 at the free border of the prepuce, 12 on the glans penis, and 10 at the urethral meatus." Bumstead and Taylor, in their work "The Pathology and Treatment of Venereal Diseases," say (page 449): "The superficial form of chancre"—i.e., indurated chancre—"is most marked on the internal surface of the prepuce by which it is protected from the air and friction, and kept free from scabs, and it is in this situation that it is most frequently met with." Mr. Barton of Dublin in his lectures on the "Pathology and Treatment of Syphilis," says: "The situation of the sore affects the amount of induration very much; thus on the corona glandis it is very well marked, while if occurring on the prepuce it is frequently very indistinct." But he does not say which situation is the more frequent. Keyes says: "The raw erosion is the most common form of syphilitic chancre. It is found in both sexes on the integument, as well as upon a mucous or semi-mucous surface." The report of the Venereal Committee, 1864, states: "It [i.e., the sore marked by a specific induration] may occupy the inner surface of the prepuce, the fossa, the glans, or the external integument."

The following statistics of Clerc and Fournier are quoted by Professor Van Harlingen in his admirable article on Syphilis in "Ashhurst's International Encyclopædia of Surgery," vol. ii., p. 460:—

Clerc's figures.—Internal surface of the prepuce, 63; balano-preputial fold, 171; orifice of the prepuce, 35; frænum, 14; glans, 12; meatus urinarius, 33; cutaneous surface of penis or prepuce, 58; scrotum, 3; peno-scrotal angle, 5—total, 394.

Fournier's figures.—Glans and prepuce, 314; preputial furrow, 60; multiple, that is showing chancres of the furrow and prepuce, or of the furrow and glans, 11; meatus urinarius, 32; intra-urethral, 17; scrotum, 7; peno-scrotal angle, 4—total, 445.

Our figures.—Prepuce, inner and outer, 166; prepuce, furrow, and corona, 37; body of penis or sheath, 32; prepuce and furrow, 31; furrow, 29; meatus, 15; glans, 13; frænum, 9; corona, 7; furrow and corona, 7; prepuce and glans, 7; sheath and prepuce, 5; prepuce and frænum, 5; furrow and glans, 4; other situations mostly compound, 33—total, 400.

The larger proportion of chancres were thus found to be on the prepuce, and of these the majority were situated on the inner prepuce, comparatively few being on the outer. If in Fournier's statistics the numbers on the glans and prepuce had been given separately, and if Clerc's figures for the "balano-preputial fold" and "orifice of the prepuce" be added to those of the "internal surface of the prepuce," the proportion of chancres upon the latter would probably be as marked as in our cases. The situation will, of course, be determined by circumstances. Many of those seen on the prepuce and furrow, prepuce furrow and corona, prepuce and glans, and prepuce and frænum, were probably at first situated on the inner prepuce, extending to adjacent parts before they were seen by us. The condition, moreover, of the parts must have some influence on the site of initial lesion, an excoriated state being especially favourable for absorbing the syphilitic virus.

While, on the one hand, it would be absurd to attach too much importance to this question as to the exact site of the initial lesion of syphilis, it seems to me that, looking to the past history of this disease, it would be unwise to ignore any well-established fact, or to attempt to say positively of how much or of how little importance it is. Taken in conjunction with the period of incubation which almost invariably precedes the infecting sore, it is somewhat significant that the situation of the latter should more frequently be superficial, and so comparatively rare on the frænum, a place where we might expect the virus to lodge.

Those who have had experience in statistics will know

Digitized by Google

how difficult it is to take and preserve accurate returns of such details as are here given. I could have wished that they had been even more complete, especially that the numbers for the inner and outer prepuce had been given separately. There are some other points on which it would be interesting, and perhaps profitable, to have accurate records. These are—(1) The relative proportions of single and multiple infecting sores; (2) the comparative frequency or rarity of the absence of induration; (3) the varying periods of incubation in days; and (4) the proportionate frequency of the presence of indurated inguinal glands. It is somewhat remarkable, seeing how greatly syphilitic diseases prevail in these kingdoms, so few English statistics have been compiled, most of them being those of foreign countries. Two possible reasons for this are the paucity in this country of lock hospitals and lock wards, and the immense labour involved in preparing such statistics. To reduce this latter as much as possible I am having printed forms prepared which will enable us to record with ease all the preceding details, as well as the exact site of the initial lesion. I shall probably be able to give these in some future issue of THE LANCET from the returns of a large number of cases. Should any readers of THE LANCET desire to have a specimen of these forms, I shall have much pleasure in forwarding it. We have also observed the site of the infecting sore in females, but the number is not sufficiently large for statistical purposes; these I shall hope also to give in a future article.

(DORSET HOUSE BRANCH.)

CASE OF REMOVAL OF LARGE INTRA-UTERINE FIBROID.
(Under the care of Dr. PERCY BOULTON.)

E. B——, aged thirty-five, was admitted on account of profuse loss of blood at her periods which had rendered her exceedingly anæmic, and latterly, during the whole intra-menstrual interval, she had suffered from a foul-smelling discharge. Being single and the hymen intact, she had never undergone a vaginal examination. Dr. Percy Boulton found the os dilated and the brim of the pelvis completely blocked by a fibroid tumour a little larger than the fœtal head at term. A broad anterior attachment was made out, and it was found that the presenting part was decidedly sloughy and causing the foul discharge complained of.

The patient was prepared and the tumour was removed. Owing to the large size of the growth and the smallness of the vaginal outlet, it was necessary to trisect the tumour. The wire of the écraseur was placed over it and tightened sufficiently to act as a tourniquet round the thick pedicle, while the other portions were removed with another instrument, the last third being removed by the écraseur that was first placed round the pedicle, and in this manner the severe hæmorrhage which was anticipated from so broad a base was prevented.

During the first twelve hours the vagina was packed with wool impregnated with iodoform and eucalyptus, and afterwards the parts were douched several times a day with iodine lotion.

Some slight pelvic cellular inflammation occurred afterwards, from absorption of the discharge through the stump, but the temperature never exceeded 102·4°, and the patient made an excellent recovery and left the hospital convalescent after seven weeks.

As the usual difficulties in removing large tumours were much increased by the small space for manipulation, and a broad pedicle is always an element of danger after the removal of fibroids, the case was regarded as interesting and satisfactory.

WOLVERHAMPTON AND SOUTH STAFFORDSHIRE GENERAL HOSPITAL.

CASE OF STRANGULATED INGUINAL HERNIA; DEATH FROM INTESTINAL HÆMORRHAGE; REMARKS.
(Under the care of Mr. KOUGH.)

FOR the following notes we are indebted to Mr. J. W. Batterham, B.S. Lond., house-surgeon.

George S——, aged thirty, was admitted at 1.30 P.M. on September 5th, 1884. He stated that he had been ruptured all his life, had never worn a truss, and had always been able to reduce his hernia when it came down; that when lifting a mass of iron early on the morning of admission the rupture came down in larger amount than usual, and he had been unable to reduce it. Patient was a spare, delicate-looking man, but had never suffered from any other ailment than his hernia. He was cold and pale with a small, feeble pulse.

Upon examination a scrotal hernia was found on the left side about the size of the patient's head. The tumour was not very tense and was resonant on percussion, but succussion showed it to contain a considerable amount of fluid. Gentle efforts at reduction being ineffectual, the patient was placed in a hot bath for twenty minutes, and then removed to bed with hot bottles to his feet and an icebag on the scrotum. He was left in this condition till 7 P.M. During this time he was extremely restless and complained of great thirst. He vomited a few ounces of bilious matter. At 7 P.M. he was becoming extremely collapsed, and complained of dyspnœa. The hernia was slightly smaller than on admission. At 7.30 P.M. chloroform was administered and the hernia readily reduced. The patient's pulse improved somewhat under the influence of the anæsthetic, from which he soon recovered, but he rapidly reassumed his collapsed condition, and died about 9.30 P.M.

Necropsy, sixty hours after death.—The sac in its empty condition was nine inches long and nine inches in circumference. It appeared to be the sac of an acquired inguinal hernia of the external or indirect variety. The mouth of the sac was large, admitting three fingers. The pelvic cavity was full of blood-stained serum, a little of which was also found in the sac. The last nine feet of the ileum, the cæcum, and ascending colon (in all, about one foot of large bowel) were of a dark-purplish tint, and had evidently formed the recent contents of the sac, though the exact point of strangulation could not be detected. A long meso-cæcum was present. The above-mentioned ten feet of intestine were ligatured and removed. The peritoneal surface was firm and polished. On laying the gut open about a pint and a half of blood escaped. The inner surface of the bowel was of an even darker colour than the outer, and presented throughout large slate-coloured patches of ecchymosis. Peyer's patches and the villi were very well marked, being turged with blood. No ulceration or other sign of disease was detected. The heart was anæmic, but healthy; the lungs were congested and œdematous; the liver congested; other organs were normal. The large venous trunks contained hardly any blood.

Remarks.—The above case presents several unusual features. 1. The large size of the hernia. 2. The great length of the mesocolon and mesocæcum, which allowed the first 12 in. of the large bowel to occupy the sac of a left inguinal hernia. 3. It is difficult to account for the presence in the bowel of so large a quantity of blood. The large size of the opening into the sac, and ease with which the hernia was reduced under chloroform, do not point to a very severe strangulation of the bowel by the neck of the sac. To what then was the intense congestion and subsequent hæmorrhage due? Is it possible that a twisting and stretching of the mesentery may have produced so grave an interference with the circulation? The patient presented the symptoms of internal hæmorrhage, and his death was apparently due to this cause. I am not aware that any case has been reported where death after hernia has occurred in this manner.

CASE OF RUPTURE OF THE LIVER; NECROPSY.
(Under the care of Mr. KOUGH.)

The notes of this case also have been furnished by Mr. J. W. Batterham, B.S. Lond., house-surgeon.

John B——, aged twenty-three, was admitted into the hospital at 2.40 A.M. on Sept. 5th, 1884, having been run over by an empty railway truck (weighing about four tons)

Digitized by Google

an hour and a half previously. He was conscious, but cold, pallid, and almost pulseless. He was found to have sustained a simple fracture of the right femur, a compound fracture of the right forearm, and a simple fracture of the ribs on the right side. His respiration was thoracic and chiefly confined to the left side. Pain was complained of in the upper part of the abdomen, being felt most acutely in the epigastric region. There was no retching or nausea. Patient exhibited extreme restlessness and complained much of thirst. He died about two hours after admission.

Necropsy, eighty hours after death.—The fifth and sixth ribs on the right side were found to have been fractured just in front of their angles. The bruising of the tissues, &c., showed that the wheel of the truck must have passed over these ribs about an inch external to their cartilages. Hæmorrhage had occurred into the old adhesions by which the right lung was universally covered. The thoracic viscera were otherwise normal, and the diaphragm intact. On opening the abdomen about thirty ounces of blood were found in the posterior part of that cavity. The abdominal viscera were all intact except the liver. Extending along the posterior border of the right lobe, between the attachments of the coronary ligaments, was a rent four and a half inches long. From the centre of this a second similar lesion extended forwards across the upper surface of the right lobe. This T-shaped laceration affected the hepatic tissue to the depth of two inches.

ASHBURTON AND BUCKFASTLEIGH COTTAGE HOSPITAL.

DISLOCATION OF THE HIP-JOINT IN A BOY; REDUCTION FIVE WEEKS AFTER THE INJURY.

(Under the care of Dr. JAMES ADAMS.)

W. E——, aged twelve, was brought by his mother on July 1st walking by the help of a crutch and stick. The history was that he had been thrown from a horse on May 31st and injured his left thigh.

On examination it was at once evident that there was a dislocation of the femur at the hip-joint, and the following symptoms existed, indicating it to be a dislocation into the sciatic notch—viz., shortening of about an inch, with great toe resting on the ball of great toe of right foot, leg slightly inverted; on lying on the back the left knee was advanced, and on attempting to bring the knees down to same level the back was considerably arched; almost complete immobility of the joint, and on applying Nélaton's test, the trochanter was found to be displaced.

Next day he was admitted into the hospital; and on July 4th, Mr. Ubsdell having given chloroform, Dr. Adams attempted to reduce it by Bigelow's method of manipulation, but failed. Mr. Ubsdell also tried, with a similar result. Pulleys were put on, and used with as much force as was thought prudent for nearly half an hour, without success, although the use of pulleys contributed materially to the subsequent reduction of the dislocation by stretching the tissues and muscles, breaking down adhesions, and giving more play to the head of the bone in its new situation. Manipulation was tried again, and the plan of flexion, rotation outwards, and bringing down the limb having failed, the limb was flexed and rotated outwards. When in this position it was forcibly flexed still further (the pelvis being firmly held) and the femur used as a lever, and by this leverage movement in a direction of backwards, upwards, and outwards, the head of the bone was liberated from the sciatic notch and slipped into the socket with an audible snap on bringing the limb down.

A Liston's splint was kept applied for a fortnight. At the end of a month the patient was discharged, walking well, and only the slightest limp when he walked fast.

Remarks by Dr. ADAMS.—I observed that there was a lengthening of quite half an inch after the reduction, and this is usually attributed to deposits in the acetabulum, preventing the head of the bone returning to its normal position. May not this lengthening be more probably due to the fact that the muscles attaching the femur to the pelvis being, as in my case, weakened by disease, and then stretched by pulleys, are unable to pull the bone up to its proper place at first, but that when they have recovered from these effects the bone is once more brought to its natural length? I would also call attention to the leverage movement mentioned above, as I do not see it alluded to in the surgical works I have been able to consult.

Medical Societies.

CAMBRIDGE MEDICAL SOCIETY.

AT the meeting on August 8th, Dr. J. B. Bradbury in the chair,

Mr. DEIGHTON related a case in which Alarming Symptoms occurred during the Willing Game. In November, 1883, he was summoned in urgent haste to see an undergraduate. He found him surrounded by his friends, who said they had been playing the willing game, and that he had been blindfolded and whirled; soon afterwards he became tottering on his legs and went into a state of convulsions. When seen he was tossing about on a sofa, with face slightly flushed, the movements of the arms and legs being most irregular, almost equally exaggerated on both sides. The muscles of the face and neck were least affected, but he spoke in a jerky way, and on putting out his tongue it was protruded and withdrawn suddenly. He was quite conscious, clear and collected, and said that he tried to prevent himself tossing about, but could not help it. The pupils acted to light and were natural in size. He was ordered a bromide draught and told to go to bed. The next morning he was quite well. He said he had spent a bad night, tossing about until five A.M. before he went to sleep, but there was now only an occasional twitching in the legs. He was of a nervous and excitable disposition, but never had fits, rheumatism, or chorea. The heart sounds were normal. He was liable to excessive frequency of micturition on any excitement. The attack had all the appearance of chorea, the short duration of the seizure being the only difficulty to that view. Mr. Deighton thought that if chorea were regarded as a functional affection in which a mere exaggeration of those muscular movements which are constantly taking place in the body occurred, and that a shock by removing the controlling power of the higher centres allowed the lower centres to have full play, then this case was in the same way capable of explanation.

Mr. WHERRY related a similar case, in which the symptoms, though not so definite as in Mr. Deighton's case, were nevertheless sufficient to alarm the patient's friends. He was sent for one evening to see an undergraduate who had become suddenly ill during the willing game. It appeared that his friends had blindfolded him in the usual manner and were willing him to do some simple action, when suddenly he became weak in the knees and had to be helped to a seat. The handkerchief was removed at once, but the patient did not seem at all himself. He found him leaning against the mantelshelf, looking fixedly downwards in a dogged and morose attitude; he answered questions in monosyllables in a hesitating way, not stammering, but with a jerk and without expression. Usually, his friends said, his manners were natural and polite. The pupils were dilated, with no action to light and his memory was a blank as to the details of the game. He was sent to bed, and when seen the next morning he was better; his pupils were normal and active to light, but his manner was still odd and his speech remarkable. When advised to leave Cambridge for a few days' change, he refused rudely, but was afterwards persuaded by his friends, and returned quite well.

Dr. BRADBURY related a case of Ulceration of the Cæcum with Pyæmic Abscesses in the Liver. The patient was an engine driver, aged thirty, who was admitted to the hospital on May 28th. He was quite well until April 25th, when he was attacked with pain in the left side of the abdomen. During the first week of his illness he had two or three violent fits of shivering, and vomiting had been present from the first and continued until about a week ago, and he had also had some diarrhœa. He had lost much flesh, and was troubled with a slight cough. On admission he was much emaciated; skin hot; tongue dry and brown; pulse 84; temperature 101·8°; abdomen lax, tender on pressure, especially in the left iliac fossa; no spots; a patch of dulness over the base of the left lung behind, with deficient breathing and fremitus; liver dulness normal; splenic dulness from the seventh to the eleventh rib, extending back nearly to the angle of the scapula; the urine contained no albumen. On June 2nd he had a rigor, with pain in the abdomen and diarrhœa, and profuse sweating afterwards. The rigors and sweats were repeated for several days, and the temperature chart showed

Digitized by Google

great diurnal variations, on one occasion dropping from 106·6° to 96·4° in less than twelve hours. The physical signs remained about the same, except that on June 18th the liver dulness extended from about the fourth rib to a quarter of an inch below the edge of the ribs, and on the 23rd to two inches below the ribs, and at one time slight jaundice was noticed. On June 25th the abdomen was swollen and very tender, and peritoneal friction was perceptible over the upper part. He remained in much the same condition until July 9th, when he was suddenly attacked with severe pain near the right nipple, the pain recurring several times with dyspnœa, and friction sound was audible. On July 10th the physical signs showed a large effusion into the right pleural cavity, with tenderness over the liver, and swelling of the legs. Death took place on July 16th. The post-mortem showed the right chest to be full of pus, of yellowish colour, and very offensive. A communication was found through an opening in the diaphragm with an abscess in the liver. The liver contained many abscesses of various sizes, the largest about the size of a lemon, which had burst through the diaphragm. In the intestine close to the junction of the vermiform appendix and cæcum was an ulcer, the size of a split pea, surrounded by congested mucous membrane; the intestinal wall was not perforated. The cause of the ulceration was not apparent and the appendix was natural. The cæcum was bound down in the right iliac fossa by adhesions of old date. The hæmorrhoidal veins and the inferior mesenteric above were filled with breaking down clot and pus. There was no evidence of any disease in the rectum or small intestines. The spleen weighed thirteen ounces and a half. Dr. Bradbury in his remarks alluded to the obscurity of the symptoms in the early history of the case and difficulty in diagnosis; the peculiarity of the pain complained of in the left side of the abdomen, and the comparatively small size of the ulcer in the bowel, the cause of the fatal pyæmia. He showed the liver and the ulcer in the cæcum.

Mr. CARVER exhibited a specimen of great Enlargement of Prostate. It was removed from a gentleman, aged sixty-seven, who only suffered from prostatic symptoms for three or four years before death. He had consulted several medical men on account of diabetes from which he suffered in addition. The patient first consulted him in 1882, when he was unable to empty his bladder, and was troubled with frequent micturition. A catheter was used three times a day and the diabetes treated by dieting. In 1883 an abscess formed in the ischio-rectal fossa, from which he suffered much pain. Early in 1884 he became much emaciated, and in May an incision was made and a large amount of fetid pus escaped, but he gradually sank. The enlargement was chiefly of the lateral lobes.

Reviews and Notices of Books.

Lectures on the Diseases of Infancy and Childhood. By CHARLES WEST, M.D. Seventh Edition. Pp. 896. London: Longmans and Co.

DR. WEST is entirely justified in the satisfaction with which he introduces the seventh edition of his Lectures on the Diseases of Infancy and Childhood. The work, in its latest form, is gracefully inscribed to Roger, Barthez, and Henoch, as the three men who in their generation have done most to increase our knowledge of the diseases of children. But in any such group which we might construct Dr. West's own name would deserve a place, perhaps not second to any other. The service which he rendered in founding the Children's Hospital in Great Ormond-street cannot be over-estimated, and the present work is still, as in its earliest form, a monument of patient, long-continued, and fruitful industry. Now that the opportunities for the study of children's diseases are so multiplied, it is well to bear in mind that Dr. West's earliest observations were made in an almost untrodden field, and that the materials for the early editions of these lectures were gathered largely from out-patient work in one of the lowest parts of London, and from post-mortem examinations made under great difficulties in the homes of the poor. The successive editions of the book mark the increasing and well-ordered experience which Dr. West obtained, with the wider opportunities which gradually unfolded themselves; and in the present volume there is nothing more striking than the readiness of the author to reconsider many of his earlier opinions, and to incorporate, when they seem to be reliable, the observations of younger workers.

We are glad that Dr. West has himself revised his own work instead of committing it to younger hands, for although, truth to say, on comparing the last edition with the first, there are many noteworthy modifications to be found in the directions for treatment, yet there is still enough in the way of thorough going statement of old antiphlogistic methods to make it instructive to students brought up in the ways of medical nihilism. Albeit none more readily than Dr. West would recognise the mental and moral gain which comes from a review of the ebb and flow of therapeutic doctrine even within our own time, and of the influence of the "zeitgeist," which in medicine, as in other realms of knowledge, insensibly modifies our most cherished opinions. Thus it happens that much of the routine management of disease in one generation falls gradually into the background, and, without any definite reason being formulated, certain plans of treatment gradually give place to others, or, indeed, in some cases to no treatment at all. Whether in the swing of the therapeutical pendulum we of this generation may see a revival of antiphlogistic methods it is difficult to foretell, but at least it is useful to have before us statements of the convictions arising out of a faithful application of such methods in past years.

It is scarcely needful to say that these lectures hold an honourable place amongst English medical books in general, and amongst books on children's diseases in particular, for their clear concise style. They are readable from beginning to end, and they possess the rare virtues amongst "special treatises" of being absolutely limited to the special diseases considered, of being thoroughly practical and free from the bondage of academical systematising. If there be a fault in style, it is perhaps the somewhat needless employment of French terms in regard to physical signs, and let us add in general the undue prominence of French statistics and of French authorities. We proceed to consider briefly the substance of the lectures, noting by the way a few points which appear to us open to criticism.

We cannot agree with Dr. West in his disparagement of the plan of taking the temperature of children in the rectum. Not only is this method more accurate, but it has the great advantage, both for doctor and child, of requiring a much shorter time than the axillary method. Three minutes are in general quite adequate for taking a rectal temperature, which will often be found higher than the temperature registered on a thermometer held in the axilla for ten minutes. Whenever the value of the various external applications of cold comes into question, the rectal temperature is obviously essential for accurate scientific observations.

From the student's point of view, some detailed account of ophthalmoscopic signs, with the necessary and important limitations as to the conclusions to be drawn therefrom, would have been more useful than the disparaging and tantalising paragraph which Dr. West quotes from M. Roger.

The lectures on tubercular meningitis are excellent, but we could have wished for a fuller discussion of what we believe to be the faulty generalisation largely owing to Rilliet and Barthez—namely, that in children tubercular meningitis and basilar meningitis are practically synonymous. It is certain that in young infants a form of basilar meningitis is not very rare in which tubercle plays no part whatever. As to the *quæstio vexata* of the recoverability of tubercular meningitis, is it not possible, in the light of occa-

Digitized by Google

cloral post-mortem suggestions, that in the rare instances of recovery tubercular deposit may have been present, but limited to a portion of the pia mater or part of the cortex? It seems inconceivable that the extensive brain softening which, whether inflammatory or dropsical, or both, is so commonly found in autopsies on tubercular meningitis, should in any given case, when once established, be recovered from, and for our own part we have always considered this softening as the most important part in the disease. But it must be remembered that it is not absolutely invariable. It seems probable that localised groups of miliary tubercles may be tolerated for considerable periods. The so-called scrofulous tumours of the brain in some cases have obviously been formed by the coalescence of such miliary groups, and it seems possible that limited inflammation in the neighbourhood of such groups may have given rise to some at least of the signs of tubercular meningitis.

The account of infantile paralysis, although on the whole satisfactory, is defective in the description of the electrical reactions, no reference being made in the paragraph on diagnosis to the noteworthy changes observed in the response of the paralysed muscles to the constant, as distinguished from the faradaic, current. The account of the morbid anatomy of this disease is also very meagre.

The lecture on disorders of the mind in children contains valuable hints on the moral perversions of children, of which the doctor is apt to take too slight a cognisance.

In the section devoted to the treatment of empyema we fail to find any expression of the author's opinion on the uses of the antiseptic method, or of the expedient, now coming largely into vogue, of removing a small portion of rib for the purpose of efficient drainage.

The lectures on croup and diphtheria are extremely valuable as giving a faithful *résumé* of the whole of this difficult subject, and as a frank and outspoken statement of the author's gradual change of view, not only on the question of identity or non-identity of the two diseases, but as to their appropriate treatment. For our own part we are not much concerned on the subject of mere nomenclature. The first question in any given case, and one not always easy to determine, is whether membrane is present in the larynx or not. Further, it may be conceded that the membranous cases are divisible into at least two types, the sthenic and the asthenic, between which there constantly occur examples of the *tertium quid*, in which we are puzzled to say what is the type. As to the all-important question of treatment, we do not deny that many of the non-membranous cases have recovered under the use of antimonials, whilst we are equally certain that these drugs have repeatedly lessened the chance of recovery of membranous cases. It must also be conceded that the non-membranous cases recover under the employment of simpler measures, such as steaming, local hot applications, &c. Post-mortem experience, indeed, shows that fatal non-membranous laryngitis is a very rare occurrence. We therefore submit that antimonial treatment in the laryngeal affections of children is in the aggregate of cases undesirable, as being *positively* dangerous in many of the membranous cases, *possibly* dangerous in the indeterminate ones (that is, those where we are uncertain whether membrane is present or not), and unnecessary in the non-membranous cases.

Dr. West gives an excellent account of the form of diphtheria which sometimes accompanies measles, and to which he was the first in this country to draw attention. In the description of diphtheritic paralysis we fail to find any reference to the remarkable disappearance of the knee-jerk in many cases, which may continue absent for a time, even after the motor power has apparently been fairly recovered.

The lectures on whooping-cough is one of the best in the book, and those on phthisis are also very valuable, especially the illustrative cases, which Dr. West quotes from his own note-books. We have always doubted the propriety of the separation of a distinct group of cases under the title of bronchial phthisis, for which Barthez and Rilliet were largely responsible, and to which Dr. West gives only a qualified assent. That in the tuberculosis of children the bronchial glands play a relatively large part goes without saying, but the interest of this feature is mainly pathological and one of degree. Cases of bronchial phthisis in children without any pulmonary phthisis must be excessively rare, although in some cases of tuberculous bronchial glands the tubercle present in the lungs may be both latent and limited in amount.

In the lecture on the cachexiæ of early life the section devoted to congenital syphilis is very disappointing. There is no reference to the early enlargement of the spleen in this disease, and only the merest mention of liver affection, in which not only the miliary gummata of M. Gubler, but large gummatous tumours and localised as well as generalised interstitial inflammations, deserve to be noted. Amongst the late manifestations of the disease, nothing is said about the characteristic form of keratitis discovered by Mr. Hutchinson, nor about affections of the choroid, nor about the special form of deafness which often develops, nor about other affections of the nervous system which have been recorded by several observers. By an unfortunate clerical error the word "molar" has been used instead of "incisor," in describing the special malformation of the second dentition described by Mr. Hutchinson. But, omissions notwithstanding (and let us add that no author could be more anxious than Dr. West to give generous acknowledgment to his contemporaries), this book remains one of the best as it was one of the earliest treatises on the diseases of children. Let us sincerely express the hope that the author may in years to come have the pleasure of issuing fresh editions of his work, bringing forth from the fulness of his experience and the wealth of his erudition "treasures both new and old."

New Inventions.

"CRAPE OF HEALTH" UNDERCLOTHING.

THE specimens of the above underclothing, of which we have made trial, seem to be very satisfactory hygienic garments. We have before insisted, as we do this week in another column, on the advantages of wool as the next covering of the constantly perspiring skin. In these garments its natural hygroscopic properties are taken full advantage of, the peculiar curly texture of the manufacture affording a greater extent of surface for absorption and evaporation. The material is extremely elastic (which elasticity it seems to retain well after being washed) and porous, affording free access of the air to the skin. Since loosely fitting clothing is as a rule warmer than tightly fitting, it may be hinted that attention should be paid to the fit of these garments, their elasticity and "doubled up" texture rendering them very adaptable. If worn tight to the skin and stretched they would lose most of their advantages. It is possible that the very curly nature of the texture might be irritating to sensitive skins: to those who can bear it, however, the slight friction excited is, of course, advantageous. These garments are made of pure silk, silk and wool mixed, &c., as well as of pure wool. They are manufactured by Strachl-Siebenmann at Zofingen, Switzerland, and may be obtained through the firm of Howell and Co., 60, Watling-street, E.C.

SYDNEY ARTHUR, a medical student, was sentenced last week by the Recorder of Dublin to a year's imprisonment for having committed several larcenies. He pleaded guilty.

Abstracts
OF
INTRODUCTORY ADDRESSES
DELIVERED AT THE
PROVINCIAL SCHOOLS OF MEDICINE
AT THE
Opening of the Session 1884-85.

QUEEN'S COLLEGE, BIRMINGHAM.

ADDRESS BY PROF. J. SAWYER, M.D. LOND., F.R.C.P.

AFTER a few words on the growth and prosperity of Queen's College which he said was confessedly one of the most advanced and best-equipped schools of medicine in this or any other country, Dr. Sawyer continued as follows:—

"Examination is the dominant 'note' of our current medical instruction. Two or three generations ago the leading principle of medical education was imitation. Now the student has set before him examinations he has to pass; then the apprentice had before him a master to imitate. Now our teaching is professorial, and to a class; then it was more personal, and to an individual. There is much that is good, doubtless, in our present system of medical education; but I am afraid we have scarcely preserved all that was good in the system we have set aside. I dare say we have been gaining in professional knowledge. Have we not been losing somewhat in professional wisdom? We have been growing in scientific precision. Have we not sometimes been loosening, and are we not in danger of losing, some of our best traditions?

"I have been asked to say a few words especially addressed to the medical students who are here this evening, and who are about to begin or to resume their professional studies. To them I say—fellow-students, you come to our school to get knowledge. It will not, I am sure, be the fault of our school if each of you do not get in it, in fair proportion, the knowledge it offers you. In our laboratories and in our books, in our museums and in our lecture rooms, and in our hospital wards and mortuaries, your several teachers, in their expositions and in their practice of the sciences and arts they profess, will continue to submit to your senses—to your eyes and to your ears, to your hands, to your noses, and to your mouths—an endless store of objective facts in the sciences and arts of medicine; and in each of you it will depend upon himself—upon your capacity, and upon the motives which guide your conduct—how much or how little of this objective knowledge you shall hold and make your own. I am not going to urge you to seek knowledge for its own sake. Knowledge, like money, health, justice, truth, and virtue, is not an end in itself, however startling this fact may be when you first apprehend it. Knowledge, in its final appraisement, is only an intermediary means, which many good people are in the habit of mistaking for an end. Now, why do you come to seek the knowledge, the particular knowledge, which we offer here? Because you want to become members of the great profession of medicine; and you are probably impelled to seek entrance into our profession for no single or separate reason alone, but rather as the resultant of a variety of motives, amongst which, scientific interest, honourable pursuit of worldly means, and pursuit of distinction, are probably the most powerful.

"Now I am afraid many of you are apt to imagine, as most people do when they begin preparation for a particular career in practical business or professional life, that all you want now, that all you need seek, as students, is knowledge. You have heard very often that knowledge is power, and you are prone to think that if you have knowledge all things else will be added unto you. But surely this is not so. Knowledge is not power, but only its material. Knowledge is only power when wisdom points its employment. Even now and here, when and whither you have come to seek and find knowledge, you must seek and find wisdom too if you would grow in the skill and grace which the life you have chosen requires of you. 'Knowledge comes, but wisdom lingers.' As a psychological product, wisdom is infinitely more elaborate than knowledge. It is knowledge kneaded with exquisite complexity into every phase of your consciousness. Wisdom is knowledge which patient experience has intimately blended with your emotions and with your desires, with your volitions and with your beliefs. It is knowledge polished and finished, qualified and refined, tested and checked, proved and guided by every pleasure which has thrilled you, by every pain which has cast you down, by every consideration you have felt of fitness and of prudence, of utility and of duty.

"The systematic knowledge we offer you here, in this medical school, in our instruction in the sciences and arts of medicine, is a matter-of-fact knowledge; it is a duly arranged aggregate of objective experience, which we present, through your senses, to your minds. Take care, take most watchful care, that you get a clear and certain perception of every fact which is placed before your understanding; for clearness of reproduction is impossible without previous clearness of perception. But the wisdom I ask you to seek, even now, is more than knowledge; it is far different. When you have begun to apply knowledge, in thought and action, to the best ends and true purposes of life, you have begun to be wise. When your self-love, your search after your own happiness, has been tempered by knowledge into prudence, and when your sympathy for others has been tempered by knowledge into duty, you have begun to be wise, for you have been putting down your pride, learning the love of mercy, and growing in the power to judge and act rightly. But, you may say, tell us how to do so much; how to get knowledge, to learn prudence and duty, and to be wise to do rightly. I answer, make it your business, even now, while you study to get knowledge in this college and in our hospitals, to study also the words, the acts, and the lives of some of those of our profession who, without trifling with truth, and without pliancy of principle, have achieved success, and honourable competence, and the love and confidence of their brethren, and so you shall learn how to prepare for professional life, as well as for professional diplomas."

UNIVERSITY COLLEGE, LIVERPOOL.

INTRODUCTORY ADDRESS BY PROFESSOR MACCANN.

PROFESSOR MACCANN, who delivered the inaugural address at University College, Liverpool, on the 4th inst., remarked that he counted himself happy in having been at a Scotch university, if only to have seen with his own eyes how a deep, genuine, disinterested, self-denying delight in science and literature and philosophy lay ready to be evoked from the great mass of the people, even from the sons of artisans and peasants. But he did not think it was mainly from these higher motives that these throngs of students went to the university. It was from the less noble, though still honourable, motive of making a career in life. And to this these Scotch universities could in a most substantial and definite way assist their students, because they could give them not only an education but a degree, a degree that was a passport to a career in life. He did not wish to speak of a degree as everything. A degree was not the end of education; no number of degrees could make a man intrinsically other than he was. A degree was but the stamp that made intrinsic value current. But it did make it current, and he dared say more than one of them could at this moment recall, as he could, cases in which even genius, knowledge, and enthusiasm had been pitifully condemned to a lifelong obscurity, drudgery, and degradation, only because they had not that outward sign and seal of academic standing to which the world was perhaps only too ready to give recognition. In a great and growing town like Liverpool there were many who had every motive and every claim to be students. Though they could not be students by profession, they had the instincts of students. They had the student's persistent love of culture; they had the student's unworldliness, almost everything except leisure. Leisure they had not; this was denied them as by a vindictive irony of fate, not seldom denied them most just when they were most conscious of its value. Such men in many cases themselves knew well the risk they ran—the danger that the necessary contractedness of their practical work would by-and-by pass into their lives, and set its brand upon their minds and character, until at last, as Adam Smith long ago pointed out, they run a risk of falling victims to a universal contractedness—contractedness in horizon, contractedness in sympathies, contractedness in the faculty and fibre

Digitized by Google

of their minds. It was to such men that something of the higher culture had perhaps its greatest worth. They would tell them so themselves. The enthusiastic study of a physical science, the loving knowledge of a favourite author, a real contact with nature through some branch of biology, a living insight into some period of history, an unaffected devotion to art—these could bring results not seldom great and beneficent, just because the dregs of time spent on the study of them were all that could be wrung from the tyrannous demands of a busy life. They could bring what was needed—a wider mental horizon, broader sympathies, and intellectual visions of a world greater and richer than that bounded by the close and stifling confines of the toiling specialised individual life; and he was free to confess that he had seldom found a purer, or more strenuous, or more self-denying devotion to culture than among some of those of whom he spoke—men who were in their souls students, but in their circumstances not students by profession.

Lord Derby next addressed the students, and at the close of his remarks presented the prizes gained during the preceding winter and summer sessions.

YORKSHIRE COLLEGE: MEDICAL DEPARTMENT.

INTRODUCTORY ADDRESS BY DR. MICHAEL FOSTER.

IN the course of his address at the opening of the fifty-fourth session of the Leeds School of Medicine on the 1st inst., Dr. Michael Foster remarked that the most powerful means of advancing the medical profession is by advancing the sciences on which the profession rests. Every little push of that science means a great bound of the profession. But the theoretical sciences on which the art of medicine is based cannot, to any large extent, be advanced by the active members of the profession. The main work of progress must be done by men set aside for that special purpose. The profession are agreed upon that; and if to any outside the profession this may appear strange, they should reflect upon what the human body is, which is the foundation of the medical art. The human body is a complicated machine, compounded of all manner of machines which are in a dim way analogues of the work of man's art. There are machines with pulleys and levers, there are telegraphs, there are telephones, there are delicate barometers and thermometers and chemical works; there is a mass of molecular machinery, and the whole machinery is governed by a nervous machinery of strange complexity, in comparison with which the most complex of human mills seems a thing of actual simplicity. And this curious, complex machinery is changing from year to year, from day to day, nay, from minute to minute. From moment to moment never is it the same. And it is a machine delicately responsive to all the changes in its surroundings. In a certain sense it is more sensitive to light than any photographic plate, more sensitive to the pressure of air than any barometer. No change outside of it, from sun to shade, from level to height, but what produces some change upon it—change which may be recognised. Some of those changes are at present hidden from us; but were we able to read all those secrets, this machinery would seem to us a microcosm. We might read in it, as in a mirror, the changes in the world without: a machine so responsive, so liable to get wrong (the getting wrong being the thing we call disease), and yet with such power of recuperation that it may be built up again from what seems but its mere wreck. Dr. Foster confessed that there were two wonders constantly before him; one wonder when he viewed the great complexity of this machine, that it holds together even for a minute; and another wonder, when he viewed its wonderful power of reparation, that it should ever come to an end. This machine cannot be studied profitably or with success at odd times in leisure moments, with loins girded for other work, or when one returns wearied from other duties. It requires the application of complex instruments, delicate instruments of precision and observation, which may be an observation of importance, determining or rectifying a great truth, which may require hours of patient preparation before the time for observation comes. And how can the doctor who is at the beck and call of his patient break away from hours of preparation just at the moment when the right time for observation has come on? Clearly there must be a division of labour. The progress of physiology is always slow, and very slow in this country. It is slow for many reasons, but it is slow for one reason especially—namely, that labourers in it are few, and because there are so few places in England where a man may at the same time gain that which a physiologist, like other people, must gain, his bread and cheese, and yet pursue his study quietly without the trouble of private practice. The greater part of the progress for the past fifty years has been carried on by labour in the laboratories of Germany. We Englishmen have played only a very small part. It is not because the German is individually more acute or more industrious than the Englishman, but it is because there are in Germany so many universities having chairs of science, which will provide for a man and set him at leisure to advance his own particular branch of science, and thus enable him to give the best of his ability to the work. People may say that in Germany these universities are largely aided by the State; but he (the lecturer) belonged to the old-fashioned school of politics, which thinks that the State should not be asked to do that which can be done as well, or even better, by the individual. He believed that the interference of the State would lead to increased centralisation of our teaching, whereas what we want is increased decentralisation. He believed in small schools, where each man could come more or less distinctly under the personal influence of the teacher; and the best style of teaching is that in which a man is taught the rudiments well, under good supervision, in the years of his apprenticeship, and has a good foundation laid in such a manner that he may be fitted to travel in succeeding years, picking up the best that other schools can teach. In concluding with the desire that the Yorkshire College should be carried on, not only as a college but as a university, Dr. Foster defined the scope of a university thus:—"The mark of a university is not the granting of degrees—for I believe that this country will one day wake up to the fearful loss of time and means in competitive examinations—but it is that which distinguishes it from a seminary. In a seminary boys and girls are taught, and the whole energy of the establishment is spent in turning them out 'taught' boys and girls. In the university they do this; but they do it in such a manner as to instil into the minds of the pupils a genuine love of science and foster a disposition to make the interests of science predominant. It seems to me a matter of very small consideration whether your degrees are given here or in London, or in Manchester or elsewhere; but it is a vital point whether the men who are tutors here are, at the same time, men who are carrying science into unknown regions."

ARMY MEDICAL SCHOOL, NETLEY.

THE forty-ninth session of the School was opened on the 2nd inst. by Professor LONGMORE, C.B. Thirty-five surgeons on probation, who passed the London Examination in August last, entered on their Netley duties, thirty for the British and five for the Indian Armies. Among the visitors was Sir Galbraith Logan, K.C.B., formerly Director-General of the Medical Department of the Army, who never misses an opportunity of showing the deep interest he takes in all that concerns the well-being of his old service.

The lecturer gave the usual hearty welcome to the newcomers, and after reading, by order, an official letter from the Director-General, intimating the concurrence of the Secretary for War in the decision of the professors in the case of a surgeon on probation who failed to obtain the minimum of marks required by the regulations at the last Netley Examinations, gave, in his usual clear and vigorous language, an account of what is expected of those who aspire to serve the State in the Medical Service of the Army, and explained the new circular regulating the examination of surgeons for promotion, and of surgeons-major who seek admission to the administrative ranks of the service. We hope this admirable discourse will be published *in extenso*.

THE REMOVAL OF FEVER CASES.—At the last meeting of the guardians of the Holborn Union a letter was read from Dr. J. W. Smythe, in which information was asked as to the duties of relieving officers in the removal of cases of infectious disease, and in which it was stated that a relieving officer had refused to grant an order for the removal of a patient unless the father made the application. The relieving officer being called upon for an explanation, denied the statement *in toto*, and Dr. Hollis was requested to immediately examine and report upon the case.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

THE General Medical Council met on Tuesday last, Sir Henry Acland, President, in the chair. In opening the proceedings,

The PRESIDENT said, in conformity with the instructions of the Council, I have summoned the present meeting at the first convenient day after the long vacation. The Council will remember that the second period of five years, for which they had elected the present President, ended on July 18th, but that, since it might be undesirable to meet at that particular date, in view of the Medical Bill then before Parliament, it was agreed that I should continue in office in order that I might call the Council together at the time most suitable either for the winding up of its arrangements under the Act of 1858, or for the further discharge of its responsible duties under that Act. This accordingly has been now done or the latter purpose. The Bill, on which so much labour and care has been expended, was withdrawn by the Prime Minister at the close of the session, after it had passed the House of Lords, but not before 185 amendments, in thirteen folio pages of more or less importance, some being in duplicate and triplicate, had been put on the notice paper of the House of Commons. The Council therefore meets now, without delay, both for the election of a President and for the grave purpose of considering the situation in which the medical education of Great Britain and of the Colonies is once more placed by causes in large measure unconnected with it. It is not my intention, under these circumstances, to make any elaborate address before retiring from the high office in which you have twice been pleased to place me. It would not, indeed, be strictly in order to do so, even if it were expedient. But I crave your indulgence while I say a very few words on the position in which, as the guardian of medical education in this country, the Council seems to be now placed. Government Bills, conferring fresh powers and imposing new duties on the Council, and this year re-constituting the Council, and assigning new and important functions to medical boards, have been four times passed through the House of Lords in the last twelve years, and have been four times withdrawn by the Government in the House of Commons without full discussion in that House. Into the causes of this abiding misfortune I will not enter, but I ask your leave to record that this failure has not been dependent on the action of the Medical Council. It is true that the work of the Council has been affected by an unusual, perhaps unprecedented, state of things. It has been hampered in its action, both from without and from within, by the sense that the powers and duties assigned by the Act of 1858 might shortly be modified or transferred. The Council, though anxious to act to the full extent of its powers, was aware that its recommendations and its conclusions were, pending the new legislation, of late years made at a disadvantage. It cannot fail to be asked, What then is now the duty of the Council? Is it to wait for further attempts at legislation? Or is it to continue to develop the work which lies before it, and, with the varied experiences it possesses, to act as though no legislation and no change were impending? It would ill become me to-day to attempt to answer these grave questions. The Council will give its own reply by its actions. But I venture to hazard the statement that three short clauses, to which no serious person could object, would, if passed into law, shortly relieve the teachers and students of modern medicine in this country of almost all their present educational uncertainties. The first, directing the Council not to admit to the Register, after a given date, any person who had not passed examinations, satisfactory to the Council, in medicine, surgery, and midwifery. The second, empowering the Council to appoint, in such manner as it deemed expedient, one or more assessors to every examining board, whatever be their number now or hereafter. The third, making it clear that the Council can, under Clauses 18, 19, and 20 of the Medical Act, inquire into the modes of teaching by the schools, as well as into those of examining by the licensing bodies. But I might go further, and say that at the present crisis it probably is in the power of the existing licensing bodies and schools, by a combined effort, to give practical effect to these several propositions without legislation, and to secure thereby peace to themselves, and in great measure to obtain more completely the confidence of the public at large. I trust that I have not, in these few words, trangressed the bounds which you would wish me, at the close of ten years as your President, to set to these remarks. I do not presume to forecast the future. Of the past I know that the work which I have had the honour of sharing with you at this table for twenty-six years since the establishment of the Council has been work of the deepest interest, and often of great difficulty. During the last ten years it has been such as to produce in me sentiments of profound gratitude and to give confidence that the Council, as the guardian of medical education in Great Britain, will deal with the present crisis alike in the spirit of patriotism and in the temper of scientific progress on which modern medicine so largely depends. Whatever may be the case elsewhere, there is no question that within the walls of this Council there can be now only one aim—viz., how to unite in using and regulating, for educational purposes, and in the best attainable way, the many forces which bear on the study of all problems connected with the prevention and treatment of disease, both personal and national. These are forces which are ever moulding anew the character of the true student for the common good of mankind. They ever need for their study and their guidance fresh thought and new exertion. I now leave the chair in which you have twice done me the high honour of placing me, that you may discharge the duty under the Act of electing a President.

The President's address was ordered to be entered on the minutes, and, on the motion of Dr. HUMPHRY, strangers were requested to withdraw during the consideration by the Council of the election of a President on the retirement of Dr. Acland. On their readmission they were informed that Sir H. Acland had been re-elected for another period of five years.

The Business Committee having been reappointed, the usual returns from the Army and Navy Medical Departments were received and ordered to be entered on the minutes.

Dr. A. SMITH, in calling attention to the returns, said it was very satisfactory to observe that in those of the Army Medical Department there were no rejections, and that in those of the Navy Medical Department there were only two rejections. It was evident, he said, that the candidates were better educated than formerly, it being very unlikely that the standard of examination was lowered.

Mr. TEALE called attention to the fact that candidates from the English bodies appeared to have been the most successful in obtaining vacancies. Two out of three, or at least a half, appeared to have been successful, while of the candidates from the Royal College of Surgeons, Ireland, only one out of twelve had succeeded in obtaining a vacancy, and of the ten candidates from the King and Queen's College of Physicians in Ireland only one had been successful, and of the eight candidates from the Royal University of Ireland one only had obtained a vacancy. Such a result seemed very curious, and appeared to require explanation.

Mr. MACNAMARA said it was gratifying to find that the education given by the Irish bodies had satisfied the examiners. It appeared, however, that the education given in London was still better, since the candidates had been more successful in gaining places. They had learned the cause of it in Ireland, and the result was that he was going to send to London a first-class apprentice of his who knew his business thoroughly, but the grinders or coachers in Ireland did not appear to have the "straight tips" for the examinations. He was certain that if the gentleman to whom he referred presented himself for the examination he would come out qualified but unsuccessful. He (Dr. Macnamara) would, however, provide against such a contingency, for he would send him to one of the best coaches in London who had the "straight tip" for the Army and Navy Examinations.

Mr. MARSHALL said that the number of licences held by the candidates ought to be taken into consideration in any comparative statement. It would be found from the returns that eighty-nine licences were held by forty-four candidates, so that it appeared probable that every one had a double licence. In any comparison it was desirable to ascertain which candidates had the respective licences.

Digitized by Google

Dr. WATSON said he had no doubt it would be found that the appointments had been given to those who had obtained the largest number of marks.

Dr. STRUTHERS said it would be very interesting to have similar returns from the India Department, and proposed—"That a copy of the returns of August, 1884, furnished to the Council by the medical departments of the army and navy be transmitted by the registrar to the authorities of the Indian Medical Department, with the suggestion that similar returns furnished to the Council from that department would be useful in order to render the statement of the medical examinations for the public services complete."

Dr. HAUGHTON, in seconding the motion, said that the Indian service was the blue ribbon of medical students, and the examination was a totally distinct one, including natural history as well as medicine. All the best men in the University of Dublin went in for that examination, and he believed that in a return of men who had obtained honours in it the students of that university would be found at the head of the list. The returns as they were laid before the Council were very imperfect, affording no information as to the final result of the year's study passed by the candidates at Netley and Haslar after the examination.

The motion of Dr. STRUTHERS having been passed, Dr. HAUGHTON moved, "And that the authorities at Netley and Haslar Hospitals be requested to forward to the Council a return of the final examination passed by the medical officers of the Army, Navy, and Indian Services." During the year, he said, the men were severely tested, and the results of their additional training ought to be known.

Dr. BANKS seconded the motion, which was adopted.

The following communication from the College of Preceptors was laid before the Council:—

DEAR SIR,—I beg to submit to you, as usual, a statement of the results of the preliminary examination for medical students and others, held by this College on the 9th, 10th, and 11th of September. The total number of candidates examined was 274, of whom 188 sat at the London centre, 27 at Bristol, 20 at Birmingham, 23 at Leeds, and 16 at Liverpool. Of the total number examined, 128 (rather less than half) obtained certificates qualifying for registration as medical students, while 4 passed in mechanics as a separate subject. Of the 142 who failed to obtain qualifying certificates, 40 failed in one obligatory subject, 24 failed in 2 obligatory subjects, 24 failed in 3 obligatory subjects, 23 failed in 4 (or more) subjects; while 31, who passed in all the obligatory subjects, failed to obtain the minimum total of marks required for a place in the second division of the second class, as required by the Medical Council. It will be seen that the results of the recent examination show a marked improvement as compared with the results of former examinations, especially in regard to the smaller number of very ignorant or incapable candidates—i.e., those who failed in three or more obligatory subjects. I am, dear Sir, yours faithfully,

October 3rd, 1884. C. R. HODGSON, Secretary.

Sir HENRY PITMAN moved that the communication be entered on the minutes, and that the College of Preceptors be thanked for the important information it contained. He said it was somewhat disheartening to find that more than half the candidates for the preliminary examination were rejected. The result, however, was better than that in March, when three out of four were rejected. Whether it was the fault of the students or of the examination itself, it was not for him to say; but he thought the question was one which the Council ought to consider. It was a grave matter for consideration that three out of four of those who sought to enter the profession should be found unfit on the ground of ignorance.

Dr. STORRAR said his impression was that the fault rested with the candidates. The College of Preceptors was a body of most experienced teachers, and most competent to test the qualifications of lads coming from school. There was an extraordinary tendency in young lads to go up for examination on speculation, and the result was that they were repeatedly rejected. The effect of the rejection by the College of Preceptors would, however, no doubt, be to raise the general preparedness of the candidates, since those who sought to enter the profession would be made aware that they must be fairly well educated. At the University of London the rejections had been for years 47, 48, or 49 per cent. When he was a young man it was regarded as a disgrace to be rejected, but that was by no means the case at the present time.

Dr. HAUGHTON thought that the result was partly due to the total ignorance of the candidates and their teachers as to what was expected of them. He considered that the best examinations were those at which there was the best *rapport* between the examiners and the teachers, and in which the fewest rejections took place.

The motion was adopted.

Sir HENRY PITMAN moved—"That the several colleges and bodies mentioned in Schedule A to the Medical Act, which conduct an examination on the subjects of general education, be requested to furnish annually the General Medical Council with a return of the number of those who had passed and of those who had failed to pass each such examination, together with a statement of the subjects on which the candidates had been examined." He said that there were fifty-six different examinations, any one of which, if passed would qualify the candidate to commence his professional studies, but the only one from which returns were made to the Council was that of the College of Preceptors. Similar returns from other bodies conducting an Arts examination qualifying for admission to the profession would, he thought, afford valuable information to the Council, and might suggest in what direction improvements might be made in the way of recognising the different bodies. Considering that the subjects were alike in all the different bodies, there ought not to be any great variation in the number of rejections. The subjects which the candidates were expected to pass were specified in the regulations of the Council, but they were not in reality all passed, and last year an application was received from one body asking to be recognised, although it excluded one important subject. The subject of mechanics was constantly omitted, and the College of Preceptors stated that only four out of 274 candidates passed in that subject.

Dr. MACNAMARA, in supporting the motion, said that the percentage of rejections at the College of Surgeons, Ireland, was about twenty-five.

Dr. HAUGHTON said it was of very little use to know how many candidates passed and how many were rejected, without knowing the questions that were asked. He would suggest that copies of the examination papers should be sent with the other returns, together with a statement of the standard in which they passed. There were in Ireland three examinations that were above suspicion—those of the University of Dublin, the Royal University of Ireland, and the Intermediate School Board. Dr. Banks could tell the Council that he would have some difficulty in making a return like that suggested. There was no special examination for medical students, and it would be impossible therefore for the three bodies he had mentioned to state the numbers of the medical students passed and rejected. The students were always recommended by the University of Dublin to spend two full years in arts before going to the medical school at all. It might be desirable to ask that a special examination, including mechanics, should be instituted for medical students, and he thought that the University of Dublin would not be indisposed to accede to the request.

The PRESIDENT said that Dr. Haughton had opened up a large and important question, which could hardly be fully discussed under the terms of his motion, and he would suggest that the whole subject could be better taken into consideration when Sir Henry Pitman brought forward the motion, of which notice had been given, for the Council to resolve itself into a committee to enter fully into the consideration of the subject of preliminary examination.

This suggestion was adopted, and the motion was accordingly withdrawn.

Mr. MACNAMARA moved—(*a*) "That medical students, seeking registration as such at the several branch offices of the General Medical Council, be required to produce, in addition to those certificates at present requisite, a certificate of moral character which shall be satisfactory to the Registrar, acting under the direction of the Branch Council, to the following effect: 'I, , do hereby certify, from personal knowledge, that is of good moral character, and a fit and proper person to be admitted to the register of medical students.'" (*b*) "That it be most strongly recommended to the several medical authorities to require candidates, previous to admission to their final examinations, to produce a certificate of good moral character, to be signed by a clergyman, a magistrate, or a registered medical practitioner." He had, he said, divided the resolution into two parts, because, while the Medical Register was entirely under the control of the Council, the medical authorities could only be recommended, not compelled, to adopt the suggestions of the Council. In the sister profession of the law, students before admission were required to bring a certificate of moral character, without which they were not allowed to commence their legal studies. It was equally important to the medical profession that there should be some guarantee as to the

Digitized by Google

character of the young men who were to be entered upon the Students' Register. Cases had come under his knowledge in which lads of infamous character had been expelled from schools, and after passing the preliminary examinations of different bodies had been entered as medical students. If his suggestion were adopted there would, he thought, be some difficulty in a student getting a certificate. As to the persons who should give such certificate of character he had advisedly excluded schoolmasters.

Dr. BANKS said he was glad to find that the College of Surgeons, Ireland, was about to follow the example of the King and Queen's College of Physicians, which required a certificate of character from its students. Such certificate, he thought, should be given, not by clergymen or by magistrates, but by two registered practitioners.

Dr. HAUGHTON thought it would be better not to define the kind of certificate required, and that it would be sufficient to state that it must be "a satisfactory certificate of character." It would be invidious to leave out the clergy, for he thought that the lowest of the clergy in the Church were on a higher platform than the lowest registered practitioners.

Dr. QUAIN suggested that the certificate should be one which should be satisfactory to the registrar.

Mr. SIMON thought it would be better to say "satisfactory to the registrar as instructed by the Branch Council." He sympathised with the object of the resolution, but he did not see what satisfactory evidence of moral character could be obtained. Every man was assumed to be of good moral character until the contrary was shown. If it could be proved that a man had committed a crime so that he could be brought under the criminal law, he could be easily dealt with, and the medical student might be called upon to sign a declaration to the effect that he had not committed any such crime. He protested against making any further addition to the dreadful certificate system, under cover of which many false statements were made.

Dr. LYON also expressed his sympathy with the object of the motion, but said he thought it would be very difficult to carry out the proposed recommendation.

Dr. PYLE seconded the amendment.

Dr. A. SMITH contended that the Council was quite prepared to vote on the question, and expressed his concurrence with the views of Mr. Simon and Dr. Lyon. He had once said that he would certify to anyone's moral character except his own.

Dr. HUMPHRY objected to throwing upon medical practitioners the responsibility of certifying as to moral character. It was hardly possible that lads of seventeen or eighteen could be excluded for want of moral character. He did not think that the proposed regulation would be of the least value in the profession.

Mr. DUNCAN, in supporting the motion, said that the very fact that such a certificate was required would be of great moral value to the students. No one could escape the responsibility of writing certificates of character; they were given in other instances, and he could see no good reason why they should not be required from persons entering the medical profession. He had often to write them himself, and his practice was to write them as honestly and as liberally as he could.

Mr. MACNAMARA declined to accept the proposal to refer the matter to a committee, which he said would only have the effect of shelving it. He accepted, however, Mr. Simon's suggestion that the certificate should be "satisfactory to the registrar of the Branch Council."

The amendment was then put and rejected, and the original motion met with the same fate. The second part of the resolution was then withdrawn.

Dr. BANKS moved "That it be a recommendation from the Medical Council to the medical authorities that they should not confer a degree or licence to practise upon any candidate until he has attained the full age of twenty-three years." He said he believed that the present regulation as to age was frequently evaded. He was strongly of opinion that in the case of most men there was not time to receive a good preliminary or professional education by the age of twenty-one. There was only one other country (Germany) in which the period of study for medical students was so short as in England; and Billroth had declared that it was shameful that a boy leaving school at sixteen should, after four years' study, be considered qualified to deal with the health and lives of the people, when he would not be allowed to deal with his own property. The minimum age in the Church of England was 23, and in the Church of Rome 24; in Austria the time required for medical study was 5 years, in Holland 6, in Belgium 7, in Denmark 5, in Norway 7, in Russia 5, in Greece 5, in Italy 6, in Portugal 5, in France 6, and in Sweden 10. It might be said that if his proposal were adopted poor lads would be prevented from entering the profession; but if parents could not give their sons a learned profession they ought to send them to trades. It was not well for the profession that there should be too great facilities for entering it.

Dr. HAUGHTON, in seconding the motion, called attention to the grave responsibilities undertaken by medical men and the delicate position in which they were often placed in regard to the domestic affairs of their patients.

Mr. SIMON said that the case of a clergyman was not analogous to that of the medical man. In the one case the main question was the competence to act as a spiritual guide, and in the other it was the earning of a livelihood. The real question in the case of the medical man was whether he was fit to undertake legal responsibilities, and whether he knew his business—a matter to be decided by his examinations. He did not think they ought to make too stringent rules as to the length of the curriculum. It would be injustice to a young man who was competent at twenty-one to extend the age to twenty-three.

Dr. LYON said that, in the event of the motion being adopted, some provisions should be made in favour of those who had been preparing for examination under the present regulations. He suggested that the regulation should not be made until after the year 1888.

Mr. DUNCAN thought that such a tremendous revolution (though he sympathised with the recommendation) ought not to be finally adopted without obtaining the deliberate opinions of the various licensing bodies, none of whom at present required a greater age than twenty-one.

Dr. STRUTHERS said he would be willing to alter the age to twenty-two, but he thought that twenty-three was rather overstepping the mark.

The debate was then adjourned to Wednesday.

WEDNESDAY, OCT. 7TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

On the motion for the confirmation of the minutes,

Mr. MACNAMARA called attention to the title "Mr." prefixed to his name in the minutes, instead of "Professor." He had written to the Registrar on the subject, and had received a reply stating that "Sir H. Pitman (chairman of the Business Committee) thinks this would be contrary to practice, and, unless the title of 'Professor' were prefixed to all who adopt that prefix at the schools where they teach, it might give rise to unpleasant feelings." Sir H. Pitman had as much right to question his title of "Professor" as he (Mr. Macnamara) had to question the prefix to Sir H. Pitman's own name, which he had so honourably won. His college (which had a Royal charter) had appointed him as a professor, and he was therefore entitled to the designation.

Dr. HAUGHTON seconded the motion for the amendment of the minutes.

The PRESIDENT pointed out that the question was one which would apply to other members of the Council, and could not be settled without careful consideration. Hitherto such matters had been left to the chairman of the Business Committee.

Sir H. PITMAN thought it was strange that Mr. Macnamara, having sat on the Council for ten years, should now for the first time raise the question of his title. He (Sir H. Pitman) had followed precedent, and if any alteration were made it ought to be under the direction of a committee appointed to consider the whole question and settle it once for all.

After some further discussion, lasting in all nearly three quarters of an hour, it was suggested by Mr. SIMON that the matter should be left to the discretion of the President. Mr. Simon also drew attention to the fact that in the document containing the appointment of Mr. Macnamara he was designated "Rawdon Macnamara, Esq."

Mr. MACNAMARA accepted the suggestion of Mr. Simon, and withdrew his motion for the amendment of the minutes.

The PRESIDENT said he desired to make a brief statement with regard to the very serious business before the Council. It was no exaggeration to say that a very serious mass of complicated and entangled work was before them. What they had practically to decide was whether they should wait for further legislation, or whether the Council should proceed

Digitized by Google

to do the work appointed for it by the Act of 1858, which, under various and increasing difficulties, it had been attempting to do during the last ten years. The first important point to be considered was, he thought, the duty of the Council in regard to the medical education of the whole kingdom. The Legislature of the country had for more than ten years been endeavouring to solve the question, and had again failed; but it had not taken from the Council the duties and powers assigned to it in 1858. The Council would have to consider what were the things it could not do without further powers. It might be said that the motions set down on the programme solved the questions to be considered; but he thought it would be desirable that the Council should first consider in committee what were the most important changes, if any, in respect to medical education and examination which should be made for efficiently carrying out the intention of the Medical Act: that the several changes, if any, be classed into (1) those which could be effected by the action of the Medical Council, the several medical bodies, and the recognised medical schools; and (2) those, if any, which might require for carrying them into effect an alteration of the law. He suggested that the representatives of the several licensing bodies should use all due effort to obtain the consent of their respective institutions to such resolutions as might be passed by the Council, with a view of immediately carrying out those which could be effected without an alteration of the law, and for their observations on the importance and desirability of those which could not. It might also be desirable that the committee of the whole Council should first deliberate in private, until matters were put into such a shape that they could be conveniently submitted as definite resolutions and publicly debated. Notice of motion to the effect he had mentioned would appear in the programme of business on Thursday.

Dr. HUMPHRY said he was greatly alarmed at the announcement of the President that the notices in the programme were to be displaced for a discussion which could not be productive of any good result. The thought of future legislation had been a hindrance to their work during almost the whole of the time he had been on the Council, and it was now their duty to proceed without any reference to such legislation.

The adjourned debate on Dr. Banks's motion to extend the age of commencing medical practice was resumed.

Dr. HALDANE thought that a young man of twenty-one who passed the required examination ought not to be prevented from practising the medical profession, seeing that he could perform any other legal function at that age. Many men at twenty-one were as well qualified as others were at twenty-three or twenty-five. It would not do to send them out as assistants, since they would be legally unqualified, and to prevent them from earning their own living would be a great hardship, especially in the case of men of small means.

Mr. MARSHALL was in favour of lengthening the curriculum, but saw no good reason in setting the proposed limit as to age except with that view.

Dr. STORRAR said that the public wants must be met, and there was a large class of persons who could not afford to pay for the professional services of an expensively educated man. The question of age should be left to settle itself. If the standard were raised too high, the poorer part of the public would go to chemists and druggists and to irregular practitioners.

Dr. SCOTT ORR thought that the lengthening of the curriculum was more important than the extension of the age for the commencement of practice. The former question could not much longer be shelved now that the list of subjects was so much extended. He approved of the suggestion of Dr. Struthers that the required age should be twenty-two, which he thought would be tantamount to adding another year to the curriculum.

Dr. HUMPHRY thought that the question should be left to the licensing bodies. To extend the age to twenty-three would be a hardship to clever and industrious pupils, who might be led away to other professions in which they could earn money at an earlier period.

Dr. BANKS, in replying, said his only object in bringing forward his motion was to raise the status of the profession. He was willing to adopt Dr. Struthers' suggestion to fix the age at twenty-two. An extension of the curriculum to five years, however, would answer the purpose he had in view, and if that were adopted he would throw over the regulation as to a minimum age. So far from his proposal being revolutionary, it was really only a return to former practice.

Mr. SIMON said he objected as strongly to fixing the age at twenty-two as he did to fixing it at twenty-three. He suggested that the motion should not be pressed, but that the whole question of the curriculum should be reconsidered with the other recommendations of the Council at the next session after conference with the authorities of the different bodies concerned.

The motion was then put and rejected.

Sir HENRY PITMAN moved—"That the proposal of the Royal College of Physicians of London and the Royal College of Surgeons of England to co-operate under the direction of the Council, do receive the sanction of the Council." The scheme submitted, he said, was the same as that brought forward last year, and it had been before the Council for a considerable time. The words "under the direction of the Council" had been inserted because they were in the Act of Parliament, and they were also used when the sanction of the Council was given last year to the proposals of the corporations in Scotland. He could not suppose that the Council would refuse to sanction that which it had been seeking to obtain during the last fourteen years. It might, perhaps, be urged that the question should be deferred till the proposals of the President in his notice of motion should be considered; but that notice only referred to questions as to which any doubt existed whether they could be carried into operation without further legislation. There could, he thought, be no question that the Council had the power to grant its sanction at once. It might be said that it was not to the interest of the bodies to combine, but that was rather a question for the bodies themselves than for the Council. If they chose to sacrifice any of their own interests for the good of the profession it was meritorious on their part. A previous scheme had been under consideration, but it had been withdrawn, and the sanction of the Council was now asked to the new proposal.

Mr. MARSHALL, in seconding the motion, said there was nothing in the scheme which would interfere with any Medical Bill that might be brought forward. It was limited in its action, and did not profess to cover the whole ground of medical reform—an object in which Parliament itself had failed. The scheme was a thoroughly practicable one; the two Colleges had considered it over and over again; there was a perfect harmony between them, and if the Council sanctioned the scheme the Colleges were prepared at their next sittings to nominate the Committee of Management to carry it out. It would be unquestionably an advantage to the student to have but one course of study to pursue in order to obtain a double qualification. Simplification and consolidation of the curriculum would be of great importance on the existing curricula of the Colleges. The student would no longer be troubled with too many lectures, but he would have three examinations instead of two. The first examination would be under the authority of the examiners of the two bodies. Years ago he had proposed such a preliminary examination for the College of Surgeons but without success; his proposal, however, had since been accepted and it worked well, attracting many new candidates to the College. The division of the examination was also matter of great importance, and if it were for that alone the scheme deserved the consideration of the Council. The period at which a man could finally get his licence was prolonged, and by dividing the examinations the candidate would be able to take time over each subject. If a man were at all distrustful of himself, he was thus encouraged to take things separately and quietly. It might be said that the present licence of the College of Physicians was all that a man wanted, since "physic" included surgery. Admitting that the College of Physicians had the right to examine and qualify a man in surgery, what were the actual facts? He had analysed one-tenth of the names on the Medical Register for 1884, and out of that number (1450) there were 153 licentiates of the Royal College of Physicians, only six of whom were contented with the single qualification, and, of those six, two lived in Canada (having no doubt a Canadian qualification also), two in London, one in Hampstead, and one in the provinces. Of the remaining 147, 139 were also members of the Royal College of Surgeons of England. That was very satisfactory as showing that the licentiates were anxious to secure good surgical qualifications. If the College of Surgeons were giving up any legal right, they ought to be complimented on their self-sacrifice in behalf of the public. The proposed scheme was not opposed

Digitized by Google

to any of the existing lines or tendencies of the medical student, but in reality encouraged them, and he thought that the Council could hardly exercise its power of refusal to sanction a scheme which had been submitted by two such honourable bodies as the College of Physicians and the College of Surgeons. As to the question of fees, the familiar "three courses" presented themselves: first, to raise the fees; secondly, to lower them; and thirdly, to leave them unaltered. An increase of the fees would have raised an uproar at once, because it would be said "You are saving money by combining your forces, and yet you demand more money." If the fees had been lowered, it might be said that the Colleges were bidding for candidates in competition with other bodies. Under all circumstances, it had been thought desirable to keep the fees as they were—fifteen guineas at the College of Physicians and twenty-one guineas at the College of Surgeons, thirty-six guineas in all. It was found that the cost of conducting the first examination was very considerable; many candidates did not go through the entire examination, some dropped off early, and the candidates for the final examination gradually diminished. The cost was more than if all the candidates went through the whole examination, and hence it had not been considered desirable to reduce the fees. As to the funds which the College expected to possess, it would not do to count their chickens before they were hatched. When the College was in possession of the funds it would be right to re-open the question of fees, and see whether they could be assimilated to those of the College of Physicians. To lower the fees at present would, he thought, be open to serious criticism. He earnestly hoped that before many hours the scheme would receive the sanction of the Council.

Dr. QUAIN said he had a very strong impression that Mr. Marshall had drawn largely on his imagination for his facts. He had boasted of the character of the examinations about to be established jointly, but he should have told the Council that they were almost identical with those now carried out by the College of Physicians. The present movement on behalf of the Colleges originated in the College of Physicians. Proposals were sometimes made by one of the Colleges and at other times by the other; but in October, 1882, one of the most distinguished Fellows of the College of Physicians proposed this resolution: "That, whereas the Royal Commission on granting medical degrees has now affirmed the principle of diminishing the number of examining boards for medical licences, the Royal College of Physicians takes the opportunity of reaffirming that principle, already adopted and acted on by it." The effect of the resolution proposed by the College of Physicians would be, not to reduce the number of boards, but to increase them. The College of Physicians must be ready to examine candidates who came from the College of Surgeons in Ireland, in Edinburgh, or elsewhere, and the College of Surgeons of England must be ready to examine candidates coming from other bodies; so that there was a new board added, and it was a perfect delusion to think that there was any diminution of the number of boards. The object of the second portion of the resolution—namely, that the President should be requested to name a committee to consider what combination the College might best enter into for examination purposes, so as to secure without further delay one complete examining board, which should be satisfactory to the profession, the Medical Council, and the Government—was that there should be a board in England that should license to practise in England, and that no one should receive a licence from either of these bodies if he did not pass the examinations of both boards; but in the note to the scheme now before the Council it was stated that anybody coming from Edinburgh might go to the College of Physicians and say, "Examine me for my licence," or he might go to the College of Surgeons and say the same, so that there was no advantage or benefit whatever to be derived from the scheme. Mr. Marshall had alluded to the fact that the scheme for the Scotch union was passed without question, but that scheme was totally different from the present one, which was not truly for union or combination. The Scotch Colleges combined; the London Colleges proposed only to co-operate. In Scotland there wss a common fund, and all the fees were paid into it, but in London the examiners could be appointed by the separate Colleges and the fees would remain just as at present. Each College would also pay its own examiners. Under these circumstances he regarded the proposed joint board as a sham. If anybody came to the College of Physicians with a surgical qualification, he was not asked a question about the College of Surgeons and its course of education. What was the price to be paid for this supposed advantage? The Council had aimed at a board examining all round, and that amiable fox living in Lincoln's-inn-fields, which never had a tail, went to the College of Physicians and said, "How beautiful I am without a tail!—do drop your tail and be like me." When the Medical Act of 1858 passed, the College of Physicians particularly felt that the privileges of the College were almost swept away, and they considered how they could best adapt themselves to the new position. They resolved to do away with the extra licentiates and to institute an examination for licentiates. They found that the old word "physic," as it was used in the time of Henry VIII., meant medicine and surgery, and that they were empowered to have one single examination for physic and surgery. From the old Charter it appeared that every physician was entitled to practise medicine and surgery. Some doubt having been thrown upon that view, no one exerted himself to get the surgical qualification recognised more than Sir Henry Pitman himself. Why, then, should the College of Physicians give up the examination in surgery? The scheme, too, broke in on the great principle of the single examining board, and the object of the proposal was to help the College of Surgeons out of its difficulty, as it had at present only power to give a half qualification. The College of Physicians only accepted the scheme under the impression that it was going to establish a grand national board. Ninety-three per cent. of the licentiates of the College also got the qualification of the College of Surgeons voluntarily, but what was more strange was that 30 per cent. of them got the licence of the Apothecaries' Society. Why should men who did this be compelled to go to this and that particular College? and why should a man who was willing to give fifteen guineas to get a perfect diploma be compelled to go to the College of Surgeons and pay twenty-five guineas more? For his own part, he felt that the Council would make a very great mistake if it sanctioned such a partial and incomplete examining board. The number coming up to the College of Physicians had increased so rapidly that there were more than 200 licentiates during the past year. That was what had stirred up the College of Surgeons. It was, in fact, the old story of the battle of shops. He would move as an amendment, "That while the Council approve of the resolution of the College of Surgeons that it will not grant its diploma to any candidate who has not passed all the examinations required for a registrable medical diploma, it is not prepared to sanction an arrangement by which the Royal College of Physicians would become a partially qualifying body, and thus entail additional expense and inconvenience upon candidates for its licence."

The amendment was seconded by Dr. PYLE.

Mr. MACNAMARA approved of the Scotch scheme owing to its comprehensive character, including, as it did, all the bodies; but the present English scheme was very different, omitting one important body, the Apothecaries' Society. If that Society had been included he would have voted for the scheme.

Mr. TEALE said he was at first greatly disappointed with the scheme, but he did not think the Council could refuse to sanction it. The step was one in the right direction, and its effect would be greater than might appear at first sight. It would settle the curriculum for the students; and the qualification would be universally recognised as a high one. That it was a co-operation instead of a union was somewhat the result of the difficulty of conducting negotiations between two large bodies, each of which had its own interests, and one of which was involved in great pecuniary responsibilities. He regretted that there was to be at first no reduction of fees, but hoped that such reduction would in future take place. The additional examination proposed would involve considerable additional cost to the students; but that might be modified if the preliminary examination could be conducted by men sent into the country from the central body to co-operate with the teachers of the schools. The long attendance in London was very costly. The paper examinations might be conducted in the country; and the candidates who were rejected on the paper examinations ought not to be required to come to London for the *viva voce* examinations. The provincial schools were becoming large and important bodies, and were entitled to every consideration.

Mr. SIMON expressed his dissent from the views of Dr. Quain as to the claim of the College of Physicians to give a qualification in medicine and surgery. The statute of

Digitized by Google

Henry VIII. no doubt stated that the members of the College of Physicians were entitled to practise surgery; but that was very different from giving licences to practise to persons not members of the Corporation. The College of Physicians had, indeed, never examined in surgery, except through Fellows of the College of Surgeons. The point had once come before the College of Surgeons, in connexion with the conjoint scheme, whether it would be justified in refusing to examine a man in surgery who had not a medical qualification. It was an open secret that the College was advised that it had that power, but on taking further advice (at his recommendation) it appeared that it had no such power, and accordingly the College obtained an empowering Act of Parliament for the purpose, so that it could now, if it entered into combination, refuse a separate examination. He believed that the College of Physicians had not obtained such an Act, and if so the difficulty appeared to him to be insuperable.

The PRESIDENT said that a second amendment had been handed in, moved by Dr. Chambers and seconded by Mr. *Simon*, to the effect that the Council was prepared to sanction the scheme "provided that full facilities were afforded to the other licensing bodies in England for co-operating with the above-named Colleges under the direction of the Council."

The debate was then adjourned to Thursday.

THURSDAY, OCTOBER 9TH.

The Council resumed the adjourned debate on Sir H. Pitman's motion sanctioning the proposed conjoint scheme of the College of Physicians and the College of Surgeons. The amendment moved by Dr. Quain was put, and rejected by thirteen votes against five. The amendment of Dr. Chambers was then discussed, and was also rejected by fourteen votes against four. Dr. Lyon moved, and Mr. Collins seconded, a third amendment, proposing to send back the scheme to the Colleges, to consider whether some arrangement could be made to include the Society of Apothecaries. This amendment was rejected by thirteen votes against four. A fourth amendment was moved by Mr. Bradford, and seconded by Dr. Chambers, sanctioning the scheme "on the understanding that the two Colleges shall not be at liberty to refuse the further co-operation of any other of the English licensing bodies if offered on terms which the Council deems proper." The amendment was rejected by fourteen votes against six, and Sir H. Pitman's motion was put and carried.

The Council then adjourned to Friday.

HOSPITAL FESTIVITIES.

UNIVERSITY COLLEGE MEDICAL DINNER.

SIR WILLIAM JENNER graced with his presence in the chair a most successful dinner held at the Freemasons' Tavern on the 4th inst., when at least 175 sat down. The chief object of the dinner, now celebrated for the second time, is to promote the social consolidation and good fellowship of the living aggregate of past and present students of the Faculty of Medicine of University College, London. In a warm-hearted and telling manner Sir William interested his large audience by stating the reasons which had led him to accept the invitation to the chair on that occasion. These may be summed up thus:—The social nature of the gathering precluded the necessity of formal speech-making; and Sir William's long connexion with the institution, of which he felt himself to be the pure outcome since he had established the foundation of his knowledge nowhere but at University College, and had never drunk of the muddy waters of the Danube. In proposing the toast of "The Health of the Chairman," Mr. Erichsen remarked in fitting language that Sir William had spoken of the good gained from University College, but not of the debt which the medical school owed him. The general cheerfulness of the evening was added to by vocal music rendered by Dr. F. T. Roberts, Mr. Price, and Dr. Beevor to the pianoforte accompaniment of Mr. H. A. Powell. A vote of thanks to Dr. Poore and Mr. C. Stonham for their services in organising the dinner was carried with acclamation, and it was announced that the same gentlemen had kindly undertaken to resume their functions at the next annual dinner.

THE LONDON HOSPITAL.

The East of London was quite *en fête* on the first of October, partly, let us hope, in expression of the feeling of the people of these regions that that institution is a veritable and kindly home to them in the dark days of sickness, but partly doubtless on account of the magic influence of the Lord Mayor, whose arrival was, though somewhat late, evidently highly popular, not only to the crowd of spectators outside, but to the gay company assembled within under a tent erected for the purpose. The proceedings were very interesting, including speeches from Mr. Buxton, Sir Andrew Clark, Mr. Jonathan Hutchinson, the Lord Mayor, and others; also the giving prizes to the successful pupils of last session and to the nurse probationers. The school promises to have a very large entry, and is altogether in a healthy and progressive state. After a hundred years of most creditable work, as Sir Andrew Clark said, they are entering on another century with a fixed determination to carry on and to carry higher the art of healing and medical teaching, and the grave moral teaching which physiology and medical experience carry with them. Mr. Hutchinson's address was a feature of the evening, and it is to be regretted that he had not more time and leisure to develop his views as to the claims of poetry on the scanty time and thought of medical students and medical men. Few of us probably are prepared to substitute the poets for the prophets, but it was interesting to note the place they take in a mind so thoroughly practical, and, we will add, reverent as Mr. Hutchinson's. His favourites among living poets are Longfellow, Browning, and especially Wordsworth. The Lord Mayor expressed his high view of the calling of medicine, and the whole proceedings were wound up with a spectacular entertainment in the grounds of the hospital which we have already noticed.

THE MIDDLESEX HOSPITAL.

The annual dinner of the past and present students of this institution took place at St. James's Hall on the evening of the 1st inst., under the presidency of Mr. Henry Morris, M.A., M.B., surgeon to the hospital. The gathering was well attended, and the occasion very successful. The toast of the evening, "Prosperity to the Middlesex Hospital and its Medical School," was proposed by the chairman, who took occasion to contrast the earlier history of the hospital with its present condition, and who paid a well-merited tribute to the devotion and fostering care of the weekly board. Mr. A. H. Ross, M.P., the chairman of the weekly board, and Mr. J. W. Hulke, F.R.S., responded to this toast. "The Health of the Lecturer of the day" was given by Dr. Spencer Cobbold, F.R.S., and acknowledged by Dr. D. W. Finlay. Mr. B. T. Lowne proposed "The Past and Present Students," which was responded to by Sir Oscar Clayton and Mr. C. L. Hudson. An admirable selection of music was given by Herr Ganz, Mr. D. Hepburn, and others, and the proceedings lasted until a late hour. In connexion with this hospital, it may be mentioned that on the occasion of the distribution of prizes which followed the introductory lecture, the chairman (Mr. A. H. Ross, M.P.) announced that Dr. Frederic Hetley of Norwood had forwarded him a cheque for £25 to be expended in a clinical prize, and had expressed his intention of providing a similar sum annually. The announcement was received with loud cheering.

SOCIETY FOR THE STUDY AND CURE OF INEBRIETY.—A meeting of this Society was held in the large room of the Medical Society on the 7st inst. The president, Dr. Norman Kerr, who occupied the chair, showed specimens of the kola-nut of South Africa (Sterculia acuminata), the professed anti-dote to drunkenness; containing a considerable proportion of caffeine, with a lesser amount of theobromine and tannin, it was a stimulant and tonic. Dr. Alfred Carpenter read a paper on the "Study and Cure of Inebriety." Inebriety, he said, was often induced by nervous shock and other physically disordered states of the nervous system. The worst effects were seen in the children of young drunkards. Penalties and imprisonments were useless. Total abstinence was essential to a cure. Mr. Oakley Hall described American legislation for the inebriate as being immeasurably ahead of legislation in England.

THE LANCET.

LONDON: SATURDAY, OCTOBER 11, 1884.

THE disastrous effect of the paralysis of Parliament on medical affairs is nowhere more apparent than in the Medical Council itself. That body has never been famous for transacting business in a business-like way. But for a year or two it has been affected with the feeling that it was under some public criticism and in yearly danger of dissolution. Such a feeling has had some wholesome influence on the Council and made its discussions a little more practical, and perhaps a little shorter than usual. But the failure of even Mr. GLADSTONE'S strong Government to effect legislation so long expected and demanded by such a consensus of opinion in and out of the profession has emboldened the representatives of "the shops" to regard themselves and their position as unassailable, and to waste the costly time of the Council over questions and discussions of mere academic or even personal interest. We say the costly time of the Council, for it is literally very costly. Thus—

In 1883 a meeting of the Council cost	£1061	0	0
One day's meeting costs	151	0	0
One hour's meeting ,, ...	38	0	0
One minute's ,, ,, ...	0	12	8

The Council should at the commencement of its meetings insist on having from its Executive Committee a statement of the absolute and necessary business to be done. We mean by this the statutory business which it was called into existence to discharge. Having got this statement and insisted further on the separate parts of the statutory business being placed on the programme in the order of their importance, it should proceed to dispose of such matters. This is the way in which any ordinary body acting under the powers of an Act of Parliament and at the expense of a poor profession would proceed. But it is not the way in which the Medical Council acts. Thus, out of about eighteen motions which constitute the programme, about six may be regarded as arising out of the statutory duties; of the rest, two-thirds are matters of theory and opinion, and refer to subjects that have been discussed over and over again by the Council. For example, the time of the Council, on its first day of session, was occupied mainly with two unpractical resolutions. The very first was a proposal by Mr. MACNAMARA that gentlemen seeking registration as medical students should in addition to all other certificates produce a certificate of moral character from a clergyman, magistrate, or registered medical practitioner, and should produce a similar certificate before admission to the final examination. The moral character of young men, of mere youths, is surely a thing to be assumed. Charity believeth all things of men at such periods of life; and even if charity in so doing is open to the charge of being a little credulous, it is better that it should be so than that inquisitorial investigation should be instituted, or that general certificates should be relied on which can be procured by anyone who does not flagrantly break the Ten Commandments. The common sense of the Council negatived this proposal, but not till a couple of hours and about sixty pounds had been spent over it. This academic discussion was followed by another equally unreal as to the feasibility of recommending to the medical authorities that they should not confer a degree or licence to practise on any candidate until he has attained the full age of twenty-three years instead of twenty-one, as at present. This also was negatived by the Council, but not much under a cost of fifty pounds and an hour and a half of time. The proposal was made by Dr. BANKS, who, it must be allowed, does not generally make unreasonable use of the time of the Council. The climax of unreasonableness was reached by no less sensible a man than Mr. MACNAMARA, who detained the Council for about forty minutes over a discussion on the title by which he ought to be addressed. This little incident was so ordinary and slight a matter in the eyes of the Council, that it has no record in the minutes. But it cost the profession £25 6*s.* 8*d.* The consequence of all these speculative discussions is not only waste of time and money, but the neglect or the inadequate treatment of graver questions, when the Council wakes up to the conclusion that its time and its patience are exhausted.

The real matters of importance disposed of at the time of our going to press are not many. It will surprise no one to hear of the re-election of Sir HENRY ACLAND to the chair of the Council, which was practically unanimous. This is the third period of five years for which he has been elected. There are obvious and grave objections to making a precedent of virtual permanency in this office; but, apart from this, there are few men so eligible, and who could place so much time and hearty service at the disposal of the Council, as Sir HENRY ACLAND. His re-election should encourage him to persevere in bringing about an understanding between public men in and out of the profession by which the chaos of our examining system and the competition of rival bodies can be remedied. By such a use of his influence he will befriend not only the medical profession, which is injured by the existing state of things, but Parliament, which is discredited by its impotence to improve it. With all that Sir HENRY said as to the gravity of the situation produced by the failure of legislation we cordially agree; but we must lose no time in saying that the situation would not be materially improved by such slight measures as he sketched in the three proposals which will be found in his address. Such proposals would not make the Council more efficient or more independent. They would not materially add to its power for securing fairness and an approach to equality in corresponding examinations in different divisions of the kingdom; and they would not diminish but increase the worry and cost of the process by which the poor student is now distracted in order to maintain twenty bodies instead of three.

A LETTER, written by Dr. WILKS, which appears in another column, gives expression to a reasonable hope and expectation that the Royal College of Surgeons of England will devote much of the munificent bequest of the late Sir ERASMUS WILSON to the purpose of providing facilities for the pursuit of anatomical, physiological, and pathological investigation and research, more especially in relation to surgery. The need of such facilities has, we have reason for knowing, often been pressed upon the attention of many individual members of the Council, though to few does it

Digitized by Google

seem hitherto to have commended itself as a practical or practicable suggestion. The alleged difficulty was a financial one. This has at length been removed, inasmuch as necessary funds have been provided in a collateral and quasi-accidental way, without interfering with the ordinary revenue of the College. It is rumoured that some members of the Council intend to propose that a large part of the funds likely soon to be at the disposal of the College shall be expended in acquiring and furnishing a place and means for scientific research such as many of the universities and colleges on the Continent possess. We rejoice that the College, though late, is now likely to emerge from the torpid and semi-hibernating condition of a mere examining body, and undertake the higher, more useful, and patriotic duty of promoting and encouraging the science and art of surgery in England. It was never designed that the business of the College should begin and end in granting qualifications to practise as surgeons. This was evidently intended to be merely subsidiary. The preamble of the first Charter granted to the existing College (40th GEORGE III.) sets forth the purpose for which the College was incorporated in the following words: — "Whereas it is of great consequence to the Commonweal of this Kingdom, that the Art and Science of Surgery should be duly promoted; and whereas it appears to us that the Establishment of a College of Surgeons will be expedient for the due promotion and encouragement of the Study and Practice of the said Art and Science," &c. This purpose is repeated in the recital of the Charter of the 3rd of GEORGE IV., and more particularly in the preamble of this Charter, in which the College is empowered to hold lands or rents to the yearly value of £2000—"And whereas it appears to Us to be expedient, in order more effectually to promote and encourage the study and practice of the said art and science of surgery ..... We of our especial grace and mere motion, at the humble petition of the said Royal College, have willed ..... that the said Royal College of Surgeons in London shall and may take, purchase, possess, hold, and enjoy any lands ..... not exceeding ..... the yearly value of two thousand pounds." It will be remembered that last March it was recommended that the College should obtain power to hold lands or rents to the yearly value of £10,000.

It is remarkable that, notwithstanding the obligations imposed by the various Charters of the College, the Council should have hitherto suppressed the higher function of promoting and encouraging the study and practice of the art and science of surgery, and should have been content to travel for eighty-four years along the old lines of its predecessors, "the Masters, Governors, and Commonalty of the Art and Science of *Surgeons*." Had the Council fully appreciated the true significance of the intention of the founders of the College, it would long ago have taken under its ægis the protection, promotion, and encouragement of surgical art and science. As it is, it has been satisfied with merely affixing its *imprimatur* on young surgeons, who have been compelled to acquire all their learning and training elsewhere. Absence of facilities for thorough and complete training in surgical and pathological science has, no less to the profit than astonishment of foreigners, compelled hundreds of our countrymen, carrying with them thousands of pounds, to seek in continental schools the help which the College of Surgeons might at any time from its foundation have supplied as effectually at home. Henceforth the Council will have no valid excuse for its *laissez-faire* policy in this matter.

THE disgusting and dangerous condition of the Thames has been proved by such a mass of scientific evidence, and has, moreover, been rendered so evident to the popular nose during the recent hot weather, that no one now doubts that some remedy will shortly be attempted. The Royal Commission appointed to inquire into the matter is still sitting, and is engaged in the consideration of remedial measures; but it has already published a report in which very strong opinions in regard to the existence of the nuisance are stated; and Mr. THORNHILL HARRISON, in his recently published report, goes even further, as will be seen from the following quotations:—"It is probably no exaggeration to say that at the present time [August] there is a month's sewage from the metropolis oscillating backwards and forwards between Greenhithe and Teddington. ..... The water during high spring tides is polluted even up to Richmond, and it leaves a foul deposit on the banks of the river and on the towing-path. This nuisance is complained of by the Richmond people. The Thames in its present condition can only be compared to a huge sewage tank, which for now many months has not been cleaned out. It is notorious that under such circumstances the sludge, wherever it settles, becomes putrescent and most offensive. ..... The Metropolitan Board of Works deny altogether that there is any deposit of sludge in the Thames from their sewage. I feel confident that this contention is no longer tenable; for there must be a considerable deposition of mud wherever the water is moderately quiescent."

At last it appears the Metropolitan Board of Works has changed its front, and has come forward with a new scheme for dealing with the sewage of the whole of London, including that of the Lower Thames Valley. Sir JOSEPH BAZALGETTE, it is said, now proposes that the sewage of South London shall be carried under the Thames to the northern bank of the river, to join the northern sewage, the united stream being then carried down to Sea Reach to be discharged near the Essex shore during the ebb tide, and so carried to sea. As for the sewage of the Lower Thames Valley, that is to be carried through a new main sewer, through Kingston to Crossness, where it would join the sewage of South London. Considering that the nuisance is the work of the Board, and that the money of the ratepayers has been spent recklessly in the fruitless endeavour to prove that no nuisance exists, the public will regret that some other authority cannot be entrusted with the reform. But reform is so urgent that we care little who effects it, and if this scheme is shown to be the best which is offered, we trust it will be adopted without delay. Let it be remembered that we are living in extreme risk. The cholera is in Europe. It was here not many years ago, and may come again next year. A river which has been converted by human stupidity into a huge open sewer is a home to which it would naturally fly, and from which no one can tell how soon death might radiate.

The greatest objection to Sir JOSEPH BAZALGETTE's scheme is that it would take years to accomplish. There are

Digitized by Google

other objections of course. It is painful to think of the waste of phosphates involved. We ransack the world for phosphates. The supply is large, but not inexhaustible; and yet we seem to be ever adopting new contrivances for throwing them into the sea. This is a sin, and England is, as LIEBIG long ago declared, the greatest sinner. Native phosphates represent the food supply of future generations, and seem intended by nature to replace the unavoidable losses incident to any system of agriculture. For this reason we should be inclined to give the preference to any system of sewage disposal which avoided the total waste of manurial elements, even if it were at starting somewhat more costly and less agreeable. It will cost an enormous sum of money to throw all the London sewage into the sea, and we are by no means certain that the interest of the money would not pay for a purification process, which would recover some of the ultimate elements of food and yet leave the river practically unpolluted. Of course, we do not assert that a purification process is practically possible. The cost of any such process may, for aught we know, be out of all proportion to the benefit, but the metropolis could afford to pay a good price even for an experiment, and some such system might surely be tried, as an experiment, during the years that must pass before the sewage can be sent into the sea. For the next few years, at any rate, the Metropolitan Board of Works suggests no remedy except the almost frantic use of disinfectants, a remedy which stultifies their own reiterated assertions, and is at best a miserably imperfect one.

OUR readers will have noticed that the treatment of genu valgum by osteotomy was one of the subjects specially chosen for discussion at the recent meeting of the International Medical Congress at Copenhagen. Fortunately, Dr. MACEWEN was chosen to introduce the subject, and we were able to give his paper in full in our columns a fortnight ago. He has from the first been most honourably associated with this department of surgical practice, and the record he was able to give of his results was truly remarkable. We must refer our readers to the paper itself for all the details of the picture, and must merely repeat here some of the leading facts. Dr. MACEWEN has performed osteotomy for genu valgum 820 times, and in 810 instances has performed the supra-condyloid section of the femur which bears his name. Death has followed the operation in five cases, but in no one instance was it directly traceable to the operation. Suppuration occurred in eight instances; but during the last three years in all the cases the wound has healed without the formation of pus. In all cases the operation has effected a correction of deformity and improvement in the strength and utility of the limb; while relapse, even to a slight extent, was only observed in one case. The records of other varieties of osteotomy for genu valgum are also very good, but we cannot doubt that Dr. MACEWEN'S supra-condyloid operation is destined to supersede them all on account of its safety and success, and also because it appears to be founded on more correct pathological data than its rivals.

It is surprising to notice with what rapidity osteotomy has been adopted into general surgical practice. Dr. MACEWEN speaks of having performed it 1800 times, and there are other surgeons who can record their cases by hundreds. This fact is one of the strongest proofs of the great advance of operative surgery, and especially of the treatment of recent wounds. That one surgeon can record a series of 1800 compound fractures—for that is the effect of the operation—without a single instance of pyæmia or septicæmia, or of any fatal wound complication, is a fact that nothing but the more generally known results of scientific wound treatment would make credible. The operation was at first viewed with suspicion by many surgeons, and those who practised it largely were thought to employ it with unnecessary frequency, being tempted to accomplish quickly by operation what might be attained by other and milder measures at an expenditure of more time. This was no new experience, but only an expression of the opinions of the two great surgical "parties" that always exist. We see no reason why osteotomy should be abused in this manner more than many another surgical procedure, and perhaps there is quite as great a danger of withholding from a patient the advantage he might derive from the operation were the surgeon better versed in its details or more confident of its value. Dr. MACEWEN insists that the operation should never be performed until after the stage of ramollissement has passed off, and in this he will of course be supported by every careful surgeon. The earliest age at which he has operated for genu valgum has been seven years, and he has extended the advantages of the operation to patients as old as forty-seven.

From the very large number of cases recorded by some surgeons, and their remarkable success, it is not allowable to infer that the operation is devoid of difficulty or of danger, and already instances have been published of mishaps, owing to neglect of proper precautions. If the chisel be insecurely held, or driven in a wrong direction, or the section of the parts be made at a wrong level, it is not surprising if the results differ seriously from those obtained when all these precautions are duly observed. The reason why Dr. MACEWEN and others can show an almost unbroken success in their long list of cases is that each case has been the object of special care; familiarity with the details of the operation has not been allowed to beget neglect of any necessary precaution. Those who would attain like success must adopt the same means, must regard osteotomy as an operation demanding special care in its management, and not as a simple "chipping of a bone" which can be accomplished in any fashion.

The large number of cases recorded by Dr. MACEWEN, Dr. OGSTON, and other surgeons, has now settled the position of this operation so far as statistics can do it. The safety of the procedure has been abundantly demonstrated, and it is only necessary to insist upon the importance of carefully observing all the precautions indicated by experienced operators.

SOONER or later, we are persuaded, sanitarians will discover the unwisdom of ventilating sewers, and as the phrase runs, "letting fresh air into drains" by openings on the street level. No one with a sense of smell can fail to have noticed the highly offensive emanations from street ventilators and "inlet" (!) gratings, frames and pans, under certain, or rather uncertain, states of the atmosphere. We fully recognise the difference between a mere effluvium and poisonous gas, but it must be admitted that the two are not infre-

Digitized by Google

quently associated, and the former may be accepted as a warning of the latter, although the air may be poisonous without being also offensive. All things considered, for danger and decency's sake, low level ventilation *must* be avoided. Every single purpose to be gained by it is gained by the adoption of pipes or shafts opening at high levels, and without risk. Meanwhile it is necessary to point out that these pipes or shafts must not be so placed or constructed as to act the part of supply-pipes, actually "laying on" sewer gas into bedrooms and other apartments, by being so placed as to open near windows or chimneys. Some of the most expert and painstaking architects, engineers, and professed sanitary builders are committing this folly for the sake of a little economy. They think "it will do very well," and be "quite safe" to carry up a ventilating-pipe to the roof of a house, and finish it a foot or so above or on the side of a dormer or other window. Obviously whenever the wind happens to blow in the direction of the window, or to "blow down"—as so often happens—the gas escaping from the pipe must be carried into the window. Then, again, they will not, if it be possible to avoid doing so, use cowls. They like to finish the pipe with a little umbrella, or to bend the sides in a little on themselves, and say this "does better." If there be a chimney-stack in the neighbourhood the builder thinks he does a clever thing by attaching his pipe to the brickwork and carrying it a few feet higher. Probably he has heard that it is necessary to keep it away from the chimney, so he bends it out a little at an angle, and thus ensures the occurrence of the very *contretemps* he ought to avoid—namely, the "sucking down" of the sewer gas into the chimney and its discharge into the rooms below. It is forgotten that every up-draught is accompanied by a down-draught, which either encircles it as a cylinder or in some way passes it in the chimney-shaft. This is a matter of exceeding moment. Shafts and pipes connected with sewers must be carried both *above* and *away from*, all openings—whether windows or chimneys *or* ventilators or trap-doors—communicating with houses. There is no sort of difficulty in securing this measure of safety. It only requires a firm stand on the part of the owner or "authority" against the plausible arguments of the "professional men" and "experts" engaged. Simply insist that there shall be no opening of any sort in the ground level, whether with a "charcoal pan" or however constructed. Carry all ventilators to a level above the top of the house, and quite out of the way of windows and chimneys. If this be done there need be no fear of sewer-gas. If it be not done, however excellent the "system" adopted may be, there must be fear—ay, and peril.

ON the 25th ult., a charge of negligently creating a nuisance preferred against the Mayor, Aldermen, and Burgesses of Jarrow, by Dr. W. Whamond, was after a four hours' hearing dismissed. Before announcing their decision the magistrates inspected the alleged nuisance, which consisted of a deposit of over 2000 tons of night soil in a large hole within a short distance of occupied houses.

THE Viceroy of Ireland, in some recent remarks, has shown that he appreciates the value of sanitary measures for the prevention of disease. Let Lord Spencer prove his sincerity by taking the condition of the Liffey seriously in hand. It is a disgrace to the Irish capital.

Annotations.

"Ne quid nimis."

THE LATE JOHN NETTEN RADCLIFFE.

THERE is a strong feeling among the friends of Mr. Radcliffe that something should be done to express their sense of his worth, and of the merit of his work. The more this work is considered in its public bearings the more clearly does it appear reasonable to hope that the public will not be unrepresented in the movement. A man who tracks the course of cholera and intercepts the poison at its very fountain is one of the prime benefactors of his race, and

"More than armies to the public weal."

Such was Radcliffe, though working always quietly, even with quiet humour, among the poisons that bring disaster to communities. Sir Andrew Clark has most kindly put his house at the disposal of Radcliffe's friends, and all who have the wish will probably soon have the chance of joining in a tribute to the memory of one of the best members of our profession, who was always ready to help and advise his brethren.

OUR MEDICAL CHARITIES AND THE WORKING CLASSES.

No man has done more to excite the interest of the working classes in medical charities than Mr. Sampson Gamgee of Birmingham. To him, probably, more than to any other person it is due that the working classes of Birmingham have subscribed in twelve years about twice as much to hospitals as the working men of Liverpool or Manchester. Mr. Gamgee has been discoursing on this subject in his capacity as President of the Birmingham and Edgbaston Debating Society. His address appears in the Birmingham papers of Thursday week. It is full of interest for the information it gives of the growth of working men's contributions to hospitals, from absolutely nothing forty years ago to £9664, or one-ninth of the whole expenditure, in 1883; for the generous and sympathetic sentiments expressed towards the working classes; and, not least, for the suggestion, only hinted at, that as working men are contributing so largely to hospitals—almost entirely supporting some—the question of paying the medical staff should be considered. Mr. Gamgee would be the last man to vulgarise medical service or commercialise medical institutions. He would be the last man to convert our hospitals into shops, or bring them into competition with the long-tried and faithful general practitioner, who is available to the honest poor night and day and all the year round. But he tenderly describes the case of a man prematurely turned out of a hospital imperfectly recovered from fracture, only to straiten still more the *res angusta domi*, and of others. He shows how "many of the so-called minor injuries treated in the out-patient department would be rapidly cured if the patients could be admitted into the hospital; and if for want of funds this cannot be done, great and inevitable risks are incurred." This sentence is quite as true as, and is far more serious than, the reiterated but little investigated statements about the abuse of the out-patient department. It is pitiful to think of the lasting and wearing misery of what in the poor are called slight complaints—varicose veins, an ulcer of the leg, a fistula, a skin eruption, a neglected cold,—but which in the rich would send their victim by express train to the consulting-room of the most eminent specialist in London. The poor cannot even get into a hospital with such ailments because the beds are full, or because the authorities of the hospital are bent on increasing the investments. These points are all well brought out by Mr. Gamgee, whose address is one to be studied by all who are anxious to see

Digitized by Google

the working classes helping the hospitals, and helped by the hospitals without injury to these classes or injustice to the profession.

DR. JAEGER'S SANITARY CLOTHING.

WE have already had occasion to refer to the sanitary woollen clothing system introduced by Dr. Jaeger. This reform in clothing, as has been often demonstrated at the Health Exhibition during the past season, aims at covering the body both by night and day to the degree of comfort, but not of oppressiveness, with woollen textures, and, except where leather is necessarily worn, with these only. Where leather is employed a porous variety is selected. Not only under-garments, but every other article of daily dress, bedding, and night-wear save boots, is made of wool. The coat is double-breasted, the vest, when worn (which is not always the case), forming an inner flap of the same piece; overcoats are said to be rendered unnecessary by the warmth of the other clothes. No linen is worn; the collar is of unstarched cashmere. Bed-sheets also are composed of the latter material. Felt forms the "uppers," felt and porous leather, the soles of the boots. Wall-hangings are not omitted, being evidently regarded as clothes in an impersonal and Carlylean sense. For their manufacture leather is preferred, on the ground that it is of looser texture than ordinary paper, and is, moreover, an animal product. "Animal to the animal" may, in fact, be said to be the motto of this new experiment in hygiene. It should be mentioned that these various substances are either not coloured, or are stained with fast dyes. The mere fact of animal or vegetable origin, of course, is insufficient to decide the question as to the comparative wholesomeness of clothes, but there are good physical reasons why materials allied to flannel in their structure should form the fittest covering for the skin. Their non-conducting quality is a guarantee that the body temperature shall be in great measure conserved; while, on the other hand, the shape and arrangement of their constituent hairs provide for the escape of moisture by capillary attraction, and their adaptation to both of these ends is greater than that of any vegetable fabric. The skin is constantly excreting water and carbonic acid, with fat particles and different decomposition products of the latter, such as lactic, butyric, and formic acids, to which the sour odour of sweat is due. Much of the carbonic acid is dissolved in the excreted water, and escapes with it. Obviously the kind of covering which acts as the best conductor of surface moisture with its various fluid impurities, while at the same time it hinders the escape of heat, is that which commends itself as at once the cleanliest and the healthiest. Woollen clothing is therefore suitable to warm and cold seasons alike, and to passive and active conditions. We find accordingly that it holds a predominant rank among the dress materials of temperate climates, the inhabitants of which are subject to the most frequent changes of temperature, and exhibit in their lives the fullest and most varied activity. Its arrangement on the body and its relation to the customs of dress are, however, still far from perfect. It gains nothing in wholesomeness, probably not even in comfort, from being overlaid, as it too often is, by an impervious mackintosh or sealskin jacket; nay, it loses much due credit thereby, and perhaps even more when its rightful place next the body itself is usurped by a comparatively inefficient linen shirt. It is for under-garments that woollen goods are most required, and their use in this form is much rarer than it should be. For a great many people these considerations have an especial and vital interest. Certain skins perspire much more freely than others. It is well known that persons of consumptive or rheumatic tendency, even though free from actual disease, have this peculiarity. The same is true of women in middle age, and of all whose circulatory system is for the time weakened from any cause. In these circumstances a coating of under-flannel, acting as we have shown that it does, may turn the scale between health and acute illness. The stockings of the Jaeger system are noteworthy. They are of course woollen, and have separate divisions for each of the toes. Such a contrivance is well adapted for maintaining the warmth of the lower extremities. We confess to some scepticism as to whether the combination of felt and porous leather in the Jaeger boot is equally trustworthy in all weathers. The preference for leather over wall paper also is of doubtful necessity or advantage. It must harbour dust, effluvia, and germs of disease, if present, in a way that paper does not, unless it be glazed, and if glazed its porous character is gone, and with that any superiority which it may possess. It is open to question if leather is, after all, naturally more porous than paper. These points, no doubt, admit of modification, and they cannot be said to impair in any marked degree the general practical value of a system as sound in theory as its methods are exact.

KINDNESS TO ANIMALS.

WE commend to the notice of all, but more especially to the residents and frequenters of our other seaside resorts, the very interesting and humane proceedings which took place at Scarborough a few days since, under the auspices of the Royal Society for the Prevention of Cruelty to Animals. Last year several gentlemen offered a few prizes to the owners of the horses and donkeys which at the end of the season showed that they had been treated kindly and well cared for, and the experiment has been repeated this year, the prize meeting being held in the presence of several hundred spectators. In the unavoidable absence of the Archbishop of York, Mrs. Thompson distributed the prizes on the sands, where the ponies and donkeys were paraded, and Archdeacon Blunt and Lord Londesborough made some practical remarks on kindness to animals. It is not right that such a thoughtful and excellent example should pass by without attracting the attention and publicity which it undoubtedly deserves. We fear that animals generally meet with too little kindness and consideration. People are apt, heedlessly no doubt, to think that by stopping short at ill-treatment they have been kind. Such negative kindness is far from being sufficient or satisfactory. Man owes more to the dumb creatures placed under his control. Every encouragement, therefore, should be given to any experiment having for its aim the inculcation of a truer and more active kindness to and interest in those animals which are more immediately associated with us in our daily work and leisure moments. It would be well if special prizes for kindness were given at the various agricultural, cattle, horse, and kindred shows held throughout the kingdom.

HOSPITAL SHIPS.

AT the recent meeting of the Social Science Congress in Birmingham, Dr. Braidwood drew the attention of the Health Section to the value of hospital ships. He described the various methods by which they might be constructed, and he very rightly observed that if a hospital ship is to be efficient, it is far better, and in the end cheaper, to build it outright, than to attempt to convert an existing vessel. We have some doubt whether anything except the ward that is erected on the upper deck forms a really good hospital, the difficulty as to ventilation being a very serious one as regards all lower deck wards; and though it may be said that ventilation is much more easily obtained in a floating hospital than in one on shore, yet experience has shown

Digitized by Google

that on calm days it is often very difficult to keep the lower wards sweet and fresh. There is at present a demand for hospital ships, and it should be met. But where a land hospital will answer the purpose equally well, there are distinct advantages connected with the latter institution. The administration is more difficult afloat than on shore, and where, as now often happens, the floating hospital is used for infectious diseases, it has often been found all but impossible to maintain such isolation between the different diseases as to avoid all danger of spread; whereas, in a properly arranged land hospital, this difficulty is easily overcome. The Port Authority of London, when they recently found it necessary to provide new hospital accommodation in lieu of their hospital ship *Rhin*, considered all these points, and their experience led them to decide in favour of a hospital on the banks of the river. That hospital ships can be made efficient we do not doubt, and when they are efficient they have some very distinctive advantages, but if their efficiency is to be equal to that of modern land hospitals, the expense of their construction must necessarily be very heavy. The *Castalia* is, from the financial point of view, not an encouraging precedent.

MILK EPIDEMIC AT DERBY.

MR. ILIFFE, the borough medical officer of health, reports an interesting epidemic of enteric fever at Derby, in which the source of infection was milk, and which, it is to be hoped, has already had its influence curtailed, if not quite checked, owing to the system of compulsory notification which exists in the town. On September 27th and 28th some eight to ten cases of enteric fever were reported to Mr. Iliffe, and another was heard of as having commenced on the 24th. All received their milk from a dairy in Shaftesbury-crescent, and this circumstance coupled with facts elicited as to the progress of the outbreak, strongly indicated milk as the vehicle of disease. The Shaftesbury-crescent milk was received from a dairy-farm at Mickleover in the Shardlow rural district, the milk being derived both from that farm itself and from a second farm at Sinfin. The dairy-farmer and his son were both engaged in delivering the milk to their customers, some 200 in number; and the fact that the father distributed the Sinfin milk only, whereas the son distributed all the Mickleover milk, as well as some of the Sinfin milk, coupled with the circumstance that the disease was limited to the son's customers, at once enabled Mr. Iliffe to differentiate between the supplies derived from the two farms. In short, the Mickleover milk alone came under suspicion. The Mickleover farm was then subjected to a careful sanitary investigation. In the first place it was found that the occupants had only been in possession a short time, and that during the fourth week in August, soon after their arrival, a child, aged two years and a half, sickened with enteric fever. Ten days afterwards the child's mother fell ill, and then two other children were attacked. The water-supply was derived from a well which was situated on the brink of a ditch which received the drainage from the farm-house and also from three houses above, the ditch terminating in a cesspool receiving the contents of privies in addition to pigstye drainage. The well therefore had been exposed to the risk of soakage of a large amount of filth, and since the occurrence of the first case of fever in the farmhouse, if not previously, it had also been liable to receive soakage from enteric fever excreta. The supply of milk had already been stopped on Mr. Iliffe's arrival, and the Shardlow medical officer of health was at once communicated with, in order that action might be taken to remedy the grave conditions connected with the dairy farm. Over forty patients had been attacked at the date when the report was made, the enteric fever wards at the Derby Infirmary were full, and for at least ten days more new cases might arise. Fortunately, the outbreak was heard of in its early stages, otherwise the result might have been far more serious. On the general question of milk infection it is impossible not to regard frequent occurrences, such as the one we have adverted to, as constituting a grave scandal. Sanitary authorities and their officers cannot in the present day be ignorant of the danger to the health and lives of large numbers of people which arise from the existence of insanitary circumstances such as obtained at this Mickleover farm. The Legislature has made these authorities responsible for the removal of such conditions, and it has given them ample powers to carry the removal into effect. A cursory examination revealed the obvious danger when once the mischief, which sanitary authorities are appointed to prevent, had been brought about; and a proper examination of the locality at an earlier date ought absolutely to have prevented such an occurrence. If sanitary authorities will not make that regular and systematic inspection of their districts which has been imposed upon them, irrespectively of their officers, as one of their principal duties, they should at least keep all dairy farms under constant and vigilant inspection, so that conditions of neglect such as are revealed in Mr. Iliffe's report should not carry disease and death to numbers of innocent people.

NEW CLINICAL METHOD FOR ESTIMATING UREA.

ON Monday afternoon, at the London Hospital, Dr. Ralfe exhibited a very simple and ingenious apparatus, devised by Mr. E. Squibb of New York, for the purpose of facilitating the operation for determining the amount of urea in urines at the bedside of the patient. It consists of two wide-necked medicine bottles, joined together by a piece of indiarubber tubing. In one of these bottles (A) is placed 4 c.c. of the twenty-four hours' urine, which, at the right time, by a simple contrivance, is mixed with 40 c.c. of a solution of chlorinated soda, prepared according to the directions of the United States Pharmacopœia. Decomposition of urea at once ensues, and nitrogen gas passes off freely from A to the second bottle, B, which is filled with water. A portion of this water is forced out by the gas and overflows, by means of a special tube fixed into the cork of B, into a graduated receiving glass. The amount of water so displaced and discharged into the receiving glass is the measure of the amount of nitrogen disengaged, each cubic centimetre of displaced water being equal to 1 c.c. of nitrogen, which displaced it; and 1 c.c. of nitrogen represents ·0027 gramme of urea. Thus, supposing 36 c.c. of water is displaced as the result of the decomposition of 4 c.c. of urine, then the amount of urea is $36 \times ·0027 = ·0972$ gramme of urea in 4 c.c. of urine. Now, if we divide this ·0972 gramme by 4, we get ·0243 gramme as the amount of urea in 1 c.c. of urine. Multiply this last by 100, we have the percentage amount; or multiply it by the total amount of urine collected in twenty-four hours, and we have the diurnal excretion of urea. It is not claimed for this method that it gives absolutely correct results, but that, compared with other methods, such as the hypobromite (in which pure solutions of urea yield a deficiency of nitrogen of quite 7 per cent.), it stands high as regards accuracy. The cost, moreover, is slight, and this in itself is a distinct advantage; a couple of medicine bottles, two indiarubber corks, and a few inches of indiarubber piping can be procured for a few pence, and an ordinary student can put them together. Lastly, the apparatus is so portable that it can be carried in a student's coat-pocket. The only difficulty is with regard to the chlorinated solution, which must be prepared according to the United States Pharmacopœia, and which differs

Digitized by Google

from that of the British solution in the important fact that it contains an excess of sodium carbonate. This difficulty, however, has been provided for, and Mr. Martindale of New Cavendish-street has made arrangements for the supply of the United States solution, and also the apparatus itself, accompanied with full directions as to its use. The introduction of a simple and fairly accurate method for the estimation of urea is certainly a great boon, and will no doubt extend the range of our observations regarding the fluctuations of this substance occurring in the body. Such observations are, however, especially called for in many of those constitutional disorders which are often preceded or accompanied at their onset by increased elimination of urea and phosphoric acid.

THE DRAINAGE OF CAMBRIDGE.

THE Improvement Commissioners of Cambridge are determined to die hard, and to keep up the appearance of resistance, however faint, to the very last. Their latest excuse for the masterly inactivity of past years is that now for the first time have they been brought face to face with the Local Government Board. According to their contention, the drainage scheme would have been carried out had it not been for the University authorities, who objected to, or at least could not agree with the town on, the money part of the question. It seems to us, however, that the primary duty of the Improvement Commissioners should have been to propose a rate which seemed to them equitable to both interests, and then apply for an Act of Parliament to give the rate effect. If either the University or the town thought itself aggrieved by the rate as assessed by the Commissioners, it could easily have resorted to arbitration—that is, if both parties were really in earnest as regards the sanitary condition of the town. The Improvement Commissioners now plead as a reason for their complacency that they were not brought face to face with the Local Government Board. It is true that the Board's inspectors had reported unfavourably of the drainage of Cambridge, and that notice had been given that a scheme for its improvement must be adopted, but in the eyes of the Commissioners the tone was not sufficiently imperative. Of course it is easy to read between the lines of this excuse. The Improvement Commissioners, as indeed are the sanitary authorities of large towns generally, are persons of position and influence in the town, and most of them doubtless owners of property. It is scarcely to be expected that men in this position should make themselves unpopular with the bulk of their fellow-townsmen, who, caring little for sanitary matters, are exceedingly jealous of any increase of the local burdens, even if the authorities are not unwilling to burden their own property with a heavy tax, unless the matter is peremptorily and forcibly put before them. They may admit that something ought to be done, but until the spur of necessity is applied they are indisposed to incur the odium that attaches to those who augment the rates of a district, and are naturally unwilling to increase the burden on their own property unless they see a profit in it. The case of Cambridge is like that of many places in England, especially in rural districts. Unhealthy little villages and hamlets exist in which typhoid fever and diphtheria from time to time play havoc. The rural sanitary authority consists generally of the chief landlord and small proprietors, out of whose pockets the cost of any improvements has to come. The medical officer of health for the district makes his report; it is received and discussed, and then conveniently shelved. If the medical officer is wise in his generation he will say nothing more; but if he is possessed of a desire to perform his duty, he will find his practice suffer from his unpopularity, and will lose his appointment when occasion offers. Fortunately for Cambridge, the Improvement Commissioners are at last brought "face to face" with the Local Government Board; and, still more fortunately, public opinion is strongly backing the step it has at length taken. When the undergraduates complain that they are driven from the river by its foulness, and paterfamilias writes to the newspapers of the dangers his sons are exposed to, the townsmen and University authorities will speedily find out that they have to choose between either a small additional rate or a considerable decline in the value of their property.

TRANSITORY APHASIA.

SINCE the time of Broca, aphasia dependent on serious lesions of the brain has been well recognised, but the aphasia which may be met with in the course of certain affections, and which disappears in a relatively short space of time, has been less studied. It needs no great stretch of the imagination to invent hypotheses to account for such cases of transitory aphasia, and almost any theory must, from the nature of the case, possess a certain degree of plausibility. The destruction of the functions of language, no matter to what extent, may be brought about by many other morbid conditions than mere gross anatomical alteration. The nutrition of the organs which constitute the physical basis of language, or let us say speech, may be damaged to any extent and in any degree by changes in the supply of blood, which may be of many sorts. Other means by which the nutrition of these centres may be interfered with will readily suggest themselves. Loss of speech of brief duration has been recorded in connexion with cases of general paralysis, epilepsy, hysteria, and migraine; and examples of its occurrence have been met with in cases of gout and rheumatism. The acute specific fevers, and more particularly typhoid fever, have been credited with the property of causing the same disturbance. M. Dunoyer has given, in the *Gazette Médicale de Paris*, the particulars of a case of transitory aphasia which supervened on the ingestion of five centigrammes of santonin. The patient was a girl, aged twenty, the victim of advanced pulmonary phthisis. Three hours after the self-administration of the santonin the patient was found sitting up in bed and unable to pronounce any other word than "mais." A physical examination of the nervous system was then made, on the supposition that a tubercular lesion of the brain had begun to manifest symptoms, but the investigation revealed nothing. The next day the invalid spoke, and informed the doctor that soon after taking the worm powder all objects had a yellow colour. The symptoms related to the nervous system which santonin appears to be able to produce are yellow and violet vision, hallucinations, mydriasis, perversion of taste and smell, deafness, opisthotonos, convulsions, and a tendency to walk backwards. The case above referred to is a curious example of idiosyncrasy, for the dose absorbed was almost insignificant.

"A MAGISTRATE ON HYDROPHOBIA."

UNDER this heading a contemporary seems to disparage some remarks made by Mr. Bushby, at Worship-street, on the impolicy of at once killing a dog supposed to be "mad." The magistrate was quite right. The dog ought not to be killed. If dogs which bite persons were kept alive it would often be found that they were not hydrophobic, and all anxiety would cease; whereas persons who are bitten by dogs, probably only savage from some passing illness, are worried to death by the fear of hydrophobia because the animals have been hastily killed. No possible harm can result from keeping, properly restrained, a suspected dog alive, and in many cases ease of mind would be secured. It is a strangely silly and wholly groundless notion that anything is gained by destroying the dog.

MALPRAXIS AND LISTERISM.

THE following remarkable case is reported from Germany, bearing on the question of what constitutes culpable homicide attributable to malpraxis. In April of the present year a serving man was wounded in the chest with a knife, and was treated by a practitioner without antiseptic precautions. The man died from septic poisoning, and the practitioner was arraigned on the above charge, which was upheld by the magisterial court on the ground that a medical man should be so far abreast with modern science as to avail himself of the recognised rules of treatment, and that in the case in question the practitioner should have been aware that the procedure adopted by him might lead to the death of his patient. The Reichsgericht being appealed to, confirmed this decision. The editor of the *Berliner Klinische Wochenschrift* (No. 40), in commenting on this case, the details of which are very briefly reported, points out that methods of treatment vary, and to stigmatise as malpraxis the pursuance of measures sanctioned by generations because improvements have been introduced is surely wrong. "In England," he goes on to say, "there is a large party who make no use of Lister's so-called antiseptic method, which was in question in the above case, and what would the court say if it saw the method of the open treatment of wounds which has been carried out for years at Zurich, without any suggestion of malpraxis being raised? We are staunch supporters of the Listerian method, or, to speak more correctly, of the scrupulous cleanliness and care connected with it; but to sentence a medical man for culpable homicide because he has not employed 'antiseptic measures,' supposing that he took ordinary care in disinfection and cleanliness, does not appear to us to be just." We trust that all the particulars of this case will be made public. It is hardly conceivable that such a judgment could have been given on the sole ground stated. If this indeed be the case, then we can only hope that the decision will be reversed on further appeal, which it is proposed to make. Unless there had been obvious and wilful neglect of the rules of surgery, amongst which cleanliness stands foremost, no English court would, we venture to think, pass such a judgment on a practitioner. Indeed, if the non-adoption of Listerism came to be regarded as a ground for legal intervention, the surgical part of the community would be seriously harassed.

APPARENT DEATH.

CASES of cholera patients who, having reached the algide stage, have been given over as dead while perfectly capable of recovery, have not been unfrequent in the last visitation in Italy. The following is a well-authenticated instance. Towards the close of last week Dr. Canepa, a physician in Genoa, was attacked with cholera, and before remedial measures could take effect passed rapidly into the algide stage, and, to all outward seeming, ceased to live. His death was duly announced by the practitioner in attendance, and his family had performed the last offices, pending those of the undertaker, whose arrival they were awaiting in a room adjoining that in which the body of Dr. Canepa, decently covered with a white sheet, was lying. Suddenly the door between the two chambers was seen to open, and the ghastly figure of Dr. Canepa, arrayed in burial vesture, presented itself to the thunderstruck family. In a feeble, scarcely audible voice he complained of having been left so long without attendance (six hours, in fact, having elapsed since he was given up and laid out as dead). He was immediately replaced in bed and every restorative practised on him till a physician could be obtained to perform Pacini's operation of hypodermoclysis. But in vain. The assistance which might have been effective some hours previously arrived too late, and a valuable life was lost to a wide circle, public as well as private, through the premature assumption that death was real while it was only apparent. A list of such cases, divided into two categories—first, those who have been ultimately recognised as living and rescued in time, and, second, those who have indeed been recognised as such but too late for measures of recovery—is, we understand, in preparation by an Italian physician.

BONY TUMOUR OF BRAIN.

THE formation of true bony growths in the substance of the brain is believed to be of rare occurrence. It is possible that the apparent rarity is due to the infrequency of post-mortem examinations of the cranial cavities of senile individuals. M. Witkowski has placed on record some of the particulars of an example of osseous tumour of the brain. The morbid growth was of the size of a walnut and occurred in the left hemisphere at its occipital part; it was quite independent of the pia mater or ependyma, being surrounded on all sides by brain matter. Its shape was like that of two pyramids set together at their bases; its surface was studded with a number of spicules, points, and folds, the last of which had a certain resemblance to the convolutions of the brain. The tumour was encased in a fibrous capsule, and presented many excavations filled with brownish or yellowish soft material, which was discovered on microscopical examination to be of the same structure as the marrow of bone. The fibrous capsule or periosteum of the tumour was composed of a dense connective tissue, calcified in parts. After the tumour had been decalcified by treatment with chromic and nitric acids, a hyaline ground substance was brought into existence, and lamellæ with bone corpuscles and Haversian canals were to be seen. The tumour was connected with the nervous substance by means of a delicate connective tissue strewed with amyloid corpuscles. There were no other osseous formations in any part of the central nervous system. The brain on the same side as the tumour was certainly more consistent than the right hemisphere, and the microscope exhibited an increase in the amount of connective tissue and stellate cells. The cerebral arteries were extensively thickened, and many small foci of the brain were in a state of softening. Some degree of internal and external hydrocephalus was found, and the ependyma was thickened. The brain was that of a man, aged seventy-nine years, who had never shown any symptoms of brain mischief during life. No accident could be assigned as the cause of the formation, which does not appear to have been an ordinary psammoma.

CORONERS' POWERS.

AT an inquest recently held at Penge the coroner, Mr. Carttar, came into collision with the medical man concerned in the case. It appears that Mr. Sicard was called to attend a young child suffering from the effects of extensive superficial burns. The treatment he adopted consisted of applying white paint to the injured skin and administering one grain of Dover's powder. The patient died in less than an hour after taking the powder. At the inquest a question was raised as to the propriety of the medical treatment, and particularly as regarded the use of opium. Now, Mr. Sicard was not summoned in statutory form to appear before the coroner, but received oral directions from the officer of that functionary that his attendance was required. In deference to the coroner he went, though at great personal inconvenience, but he does not seem to have met with the courtesy one would have thought his due. If reported correctly, the coroner is said to have "ordered his officer to fetch the doctor." The verdict of the jury entirely exonerated Mr. Sicard from all blame, and rightly so. His treatment of the child—whatever individual opinion may be concerning it—was in accordance with the teachings of reco

Digitized by Google

guised standard works. The fact of the child dying from shock within such a short period is in itself a justification of the course taken by Mr. Sicard, for under the circumstances a proper dose of opium was not only a desideratum, but we might almost say a necessity. It is not our purpose nor desire to advise a medical man to stand upon his strict legal rights, but clearly, if occasion requires, it is well for him to remember that even a coroner is not vested with unlimited and irresponsible power, and that he is entitled to a summons, prescribed by law. We hold that if in the course of an inquiry the coroner finds it necessary to have the evidence of a doctor, he should either adjourn the hearing or *invite*, not *demand* the attendance of the doctor on the present occasion. Unfortunately a medical man cannot claim more than £1 1s. for giving evidence in the same case, no matter how many times he has to present himself. Moreover, we have authority for saying that the Home Secretary has no funds out of which the claim for remuneration for extra services can be satisfied. Unless the case is taken up by the Treasury a medical man is under the obligation, by virtue of the coroner's warrant, to make a post-mortem examination, give evidence, and if necessary conduct an analysis of the contents of the stomach, all for the fee of two guineas.

SUBLINGUAL ULCERS OF WHOOPING-COUGH.

ANOTHER interpretation of the ulceration on the frænum linguæ met with in many cases of whooping-cough has been put forward by M. Delthil. He does not believe that the ulceration in question is due to the friction of the tongue against the teeth, because it appears several days before the onset of violent attacks of coughing. The ulceration, moreover, does not always begin on the sides of the lingual bridle, but may sometimes be seen only in the vestibule of the floor of the mouth and of the lower lip, where it leaves indelible scars. According to M. Delthil, the sublingual lesion is of contagious and parasitic origin, and due to the contact of a healthy infant with an infant affected with whooping-cough. The parasite is the microbe of whooping-cough, the same as may be found in the sputa of cases of pertussis. The sublingual lesion may be seen fourteen days after the accidental inoculation, when it is associated with the appearance of fever and vomiting; the fever disappears when the wound has cicatrised. The fever of whooping-cough is thus believed to be due to an intoxication by microbes. The sputa are believed to be dependent on ulceration of the air-passages similar in character to that found under the tongue; the cicatrices which may be discovered at autopsies are the remains of the ulceration, and the swelling of the bronchial glands is determined by the ulcerative lesion of the bronchial mucous membrane. As a consequence of these considerations, the disease can only be said to have ceased when the lesion in the mouth has healed, which fact is the announcement of the disappearance of the infectious element.

EXPERIMENTAL ACETONÆMIA.

THE presence of acetone in the blood has been considered by some authors to be the proximate cause of the symptoms collectively known as diabetic coma. Other observers have looked on the undoubted presence of acetone in the breath and urine as the result of decomposition of another chemical body of more complex composition. The importance of investigating the matter is decidedly great, looking to the frequency and danger of diabetic coma. M. de Gennes has recently published a work in which he collates the results of the experimental production of acetonæmia. Experiments were made on the guinea-pig and rabbit by the injection of varying quantities of acetone into the subcutaneous tissues. The intensity and mode of evolution of the symptoms bore a direct relation to the amount of acetone hypodermically introduced. The main phenomena observed after such subcutaneous injections were restlessness, drunkenness, muscular weakness, coma, and an alteration in respiration like that which may be met with in cases of diabetic coma; in addition, the temperature of the body was lowered and the expiratory breath strongly impregnated with the odour of acetone. It is necessary to keep clearly in mind the real significance of the results of these experiments. A series of phenomena appeared after the subcutaneous injection of acetone, which series had an undoubted resemblance to the symptoms observable in the coma of some cases of diabetes. That is all the information the researches give. We are well aware that many causes may produce the same group of symptoms, and so there is a gap yet to be filled up. Whether diabetic coma is due to acetonæmia still remains an open question.

HOSPITAL SUNDAY FUND.

MR. LANE'S second letter to *The Times* does not materially repair the damage done to his argument by Mr. Burdett's first letter. It simply leaves us with the impression that the great hospitals have suffered themselves to become a little too careless, and to rely too much on the goodness of their cause and the efforts of the Council of the Hospital Sunday Fund. Mr. Lane does not seem to think much of a collection of £33,000. It is very true that it does not fully represent the wealth of London churches, or do very great credit to metropolitan religion. But before disparaging it too much Mr. Lane would do well to ask himself one or two questions. One question might be this: How can such a sum be raised in any other way, or for any other purpose? If he thinks it such a slight achievement to raise £33,000, he would do well to try to raise an equal sum by some other machinery, and appeal to some other motives. We venture to think that the result would be to make him think a little more highly of the Hospital Sunday Fund. Another question he might put to the treasurers of our medical charities. He might ask them if they would like Hospital Sunday to be abolished, or if they regard it as inimical to their interests. In saying this we do not mean to assert that Hospital Sunday has done all it might do. It might exercise far more influence over hospitals in securing economy and efficiency of management, and over rich men in inviting large gifts into the treasury. It might also do much more than it has done in bringing the ministers of religion into personal contact with our hospitals and their inmates. We would suggest that the Hospital Sunday Fund should take steps to largely increase the amount it raises.

FUNDUS OCULI IN INSANE INDIVIDUALS.

As the result of careful observation Dr. Wiglesworth and Mr. Bickerton have come to the following conclusions on the conditions of the fundus oculi in insane individuals (*Brain*, Parts XXV. and XXVI.) That in insanity proper (including all forms of mental disease other than general paralysis) changes in the fundus oculi are found only in a small minority of cases; but that when allowance is made for changes depending upon associated constitutional conditions, errors of refraction, &c., the number of cases in which a connexion between the mental state and the accompanying change in the fundus oculi can be so much as suspected is very small. That, though atrophy of the optic nerve may succeed to a slight chronic interstitial neuritis, it is also not unfrequently primary at the optic disc; the atrophy may be complete, the patient becoming blind. That in a considerable proportion of the cases in which atrophy of the optic discs is met with spinal symptoms pointing in the direction of posterior or lateral sclerosis are prominent; but that this connexion is by no means invariable.

CHOLERA RESEARCH IN GERMANY.

ONE result of the Cholera Conference held at Berlin just before the vacation has, as we have already announced, been the institution of a course of instruction to medical officers of health and army medical officers at the Imperial Board of Health, with the object of making them familiar with the methods pursued by Dr. Koch in his cholera research. Dr. Koch conducts the classes, which are each limited to twelve members, the course lasting ten days. The first subjects dealt with are the preparation, staining, and examination of cover-glass (dried) specimens, especially of dejecta. Then come the preparation and sterilisation of the nutrient gelatine, and the production of pure cultures of the bacteria found in normal stools and in those of cases of diarrhœa, dysentery, &c. The material employed is of the simplest, the idea being to impart such an amount of knowledge as can be readily turned to account in practice.

MUSCULAR INFARCTS.

UNDER ordinary circumstances the muscular apparatus of the body receives but little attention at the hands of the performer of a post-mortem examination. M. Giraudeau has recently written a memoir on the subject of infarcts in the muscles. Three cases of advanced cardiac disease, associated with widespread atheromatous changes in the vessels, afforded the material on which the essay was written. The pectoralis major, the vastus externus, and the sartorius muscles presented infarcts of exactly the same appearance as those which are frequently seen in the spleen and kidneys. But whilst infarction of the kidneys or spleen may be brought about by a simple obliteration of one of the arteries, a number of conditions is necessary to produce an infarct in a muscle. Loss of elasticity of the vessels, either from sclerosis or atheroma, cardiac weakness, and badly oxygenated blood lead to embolism and thrombosis of a small artery, and the anastomotic circulation is insufficient under such circumstances to prevent the formation of an infarct.

BUBONIC PLAGUE.

THE existence of bubonic plague in Bagdad has been reported by the Russian papers. The rumour is, however, contradicted, in so far as the town of Bagdad is concerned, and though it is admitted that the disease has prevailed in the vilayet of the same name, yet it is declared on the authority of Drs. Lubitch and Padrilaki, that the whole district is now entirely free, and that all quarantine measures have been removed.

WE have received from the firm of E. H. Schroeder, of 137, Möckernstrasse, Berlin, copies of engravings of Rembrandt's two celebrated pictures, "Vesalius at his Dissections" and "Talpius giving an Anatomical Lesson." The engravings are of the same size as the paintings, and are admirably executed; but they are sold at a price which places them within the means of all. We believe that many of our readers will wish to possess such faithful copies of these historical pictures.

DR. ROBINSON, the Medical Officer of Health for East Kent, has been instructed by the rural sanitary authority to make a full inquiry into the circumstances of the cases of poisoning by shrimps which have recently occurred at East and West Northdown, in the Isle of Thanet.

PROF. ZEISSL of Vienna, who, with Sigmund, enjoyed the highest reputation as a syphilographer, died on the 23rd ult., after a long illness.

PROF. H. KRONECKER of Berlin has accepted a nomination to the chair of Physiology at Berne University, in succession to Professor Grützner, who goes to Tübingen. Professor Hermann of Zurich has been transferred to the same chair at Königsberg, in succession to Professor von Wittich.

AT Aberdeen the death has recently occurred of Mr. Charles Mann Crombie from injuries received through being thrown from his horse on the 1st inst. The deceased was a M.B., C.M. Aberd., and held several appointments in the city in which he lived. Mr. Crombie was forty-three years of age, and leaves a widow and large family.

A TELEGRAM has been received from Montreal announcing the death, suddenly, of heart disease, of Mr. C. Lowther Kemp, the Secretary to the Royal Hospital for Diseases of the Chest. Mr. Kemp had been for some time in failing health and had obtained a short leave of absence.

THE next primary and final examinations for the Fellowship of the Royal College of Surgeons of England are announced to commence on Nov. 21st and 27th respectively.

ON Monday next the opening of the Medical and Pharmaceutical Exhibition at Humphreys Hall, Albert-gate, will take place, at one o'clock.

THE chairs of Physiology and Pathology at the Calcutta Medical College will for the future be distinct. Dr. D. D. Cunningham has resigned his appointment to the latter office.

SOUTH AFRICAN MEDICAL ASSOCIATION.

THE first annual meeting of the South African Medical Association was held on July 18th. The report, which was read by the Secretary, stated that eighty-one members have joined the Association, of whom twenty-eight reside in Cape Town and suburbs, the remainder being dispersed throughout the colony and the Orange Free State, while Basutoland and Bechuanaland contributed one member each. Six papers were read and discussed—Dr. Ebden on Cholera; Dr. Beck on the Small-pox Outbreak at Worcester; Dr. Cartwright Reed on the Kimberley Eruptive Fever; Dr. Walker on Medical Examiners *versus* Coroners; Dr. Robertson on Corrosive Sublimate as an Antiseptic; Dr. Miss Waterston on Diseases and Remedies as seen in Native Practice. The Parliamentary Committee's Report stated that Parliament had taken no action in the direction of any medical reform. The old Medical Ordinance of 1830 has not been altered or abrogated, and the Lunacy Act is very imperfect still, in spite of the many appeals by the Medical Board during the last three years to the Government, urging alterations in and additions to the law.

After the reading of the treasurer's report, which was a very satisfactory one, and the election of office bearers for the ensuing year, the President, Dr. Ebden, delivered an address, in which he reviewed the advantages offered by the Association and alluded to several local improvements, attained, projected, or needed for the removal of disease and the preservation of health. Reviewing the history of the several small-pox epidemics which had ravaged Cape Town at different times, Dr. Ebden said that fewer persons died in that of 1882 than in any of the former ones, and that none of the vaccinated white or coloured people suffered greatly from the effects of the disease. He concluded by expressing the hope that the members of the medical profession resident in the vicinity would set their faces against the system of drainage contemplated for Cape Town, by which it was proposed to empty all the excreta and refuse into Table Bay.

THE SANITARY CONGRESS, DUBLIN.

IN the section of this Congress devoted to sanitary science and preventive medicine the following papers were read on the 1st inst.:—

Dr. Grimshaw, Registrar-General, read a paper on the Statistic Measure of the Health of Communities. After thanking the Council of the Sanitary Institute of Great Britain for the honour they had done him in selecting him to preside over this section, the author stated that attempts have been made from time to time to estimate what should be the death-rate of a healthy community, but in his opinion all such efforts have been failures, and we are driven to depend upon comparisons of death-rates in various countries with one another, or to comparisons of different portions of the same community with the whole or with one another, as the only test of the healthiness or unhealthiness of such communities. Thus the average annual death-rate of the population of England and Wales for ten years, 1871–80, was 21·4; while in London it was 22·5. In Scotland it was 21·6 for the same period. In Ireland for the same decade it was 18·3, and varied from 27·5 in Dublin to 14·1 in the rural districts of Connaught. Now, do these varying rates truly represent the relative healthiness of the different communities to which they refer? Dr. Grimshaw stated unhesitatingly that they do not; that in some of these districts the people are less unhealthy, in other cases more unhealthy, than the rates represent them to be. It has long been known that a very general relation existed between the density of a population and its death-rate—in other words, where people are packed closely together we expect to find a high death-rate. This at first sight appears to be a mere truism, but he was glad to say that the old sanitary or unsanitary maxim, "that a dense population has a high death-rate," is becoming less true every day, though statistics show that there is still a correspondence between high death-rates and density of population. It is a matter of the utmost importance when applying death-rates as a test of health that the relative numbers of the population belonging to each social class should be known. The variations in the death-rate between the classes and the subclasses are remarkable. For example, in the "professional class" the death-rate is but 19·8 per 1000, while in the "general service class" it is 36·8, or nearly double. Among domestic servants it is but 9·1, while among labourers it is 34·4, although both are drawn from the same stratum of society. Figures show that the death-rate steadily decreases as age increases, until the age period of from ten to fifteen years is reached, when the rate reaches the maximum both in Ireland and England, being 3·7 in Ireland and 3·3 in England.

Dr. Edgar Flinn read a paper on the Administration of the Public Health Act in Ireland with regard to the Duties of Officers of Health. He said the working of the Public Health Act in Ireland has, in a great majority of districts, well-nigh become a dead letter. One of the main causes of the slow progress of sanitary reform in Ireland is that there are no local boards or combinations of districts. The boards of guardians, the sanitary authorities for the rural districts, are not as a general rule opposed to sanitary reform, yet they are never anxious to move in any measure of sanitary work that will cause outlay. In lieu of having six or more medical officers of health in each district, with a superintendent medical officer of health, there should be one and only one medical officer of health, who should be a man free from the cares of practice, and whose pecuniary interests would not be perpetually at war with a due and fearless discharge of his duties.

Mr. Edward Spencer, M.A., T.C.D., read a paper on the Homes of the Working Classes in Dublin, in which after noticing the difficulties of dealing with the subject by general as distinguished from local legislation, he pointed out that Dublin is, of all cities which have carried out improvements for the housing of the poor, most peculiarly situated.

Surgeon-Major Wycliffe Jones read a paper on the Insanitary State of Small Irish Towns.

At the meeting of the Section on the 2nd inst. Dr. M'Cabe read a paper on the Water-supply and Drainage of Small Towns in Ireland; Mr. R. O. B. Furlong spoke of the Objects and Work of the Ladies' Sanitary Association; Mr. J. Byrne, M.R.I.A., of the Public Health of Kingstown; and Surgeon-General A. C. C. de Renzy, C.B., discoursed on the Sanitary Conditions under which Cholera prevails in Northern India.

The discussions in Section 2 of the Congress, which met on the 2nd inst. in the new buildings of Trinity College, were chiefly of a technical character, and related to structural plans and methods.

Mr. C. Cotton, C.E., the Engineering Inspector to the Local Government Board, delivered an address on the Public Health (Ireland) Act of 1878, so far as it related to engineering.

Professor H. Robinson, C.E., read a paper entitled "Sewage Disposal." He said the general conclusions which he deduced from his observations were as follows:—(1) That chemical precipitation is not so necessary now as it was considered to be a few years ago in cases where land for irrigation is not procurable; (2) that the efforts to profitably remove the manurial elements from sewage by chemicals not having been successful, the system should be adopted *per se* only where filtration area cannot be obtained; (3) that the success which has attended the construction of filtration areas where the land is clayey, and the successful results which have been obtained from a combined straining of sewage and of consequent filtration through small areas of artificial filters point to the adoption of one or other of these systems in many cases where chemical treatment would previously have been advised; (4) that the injurious effects of passing untreated sewage into a river depend upon not merely the relative volumes of the sewage and the river, but chiefly upon the power of the river to oxidise the sewage, which is in proportion to the extent of oxidisation of the river itself.

Mr. W. Eassie, C.E., read a paper on "The Collection and Disposal of House Refuse."

Dr. Charles A. Cameron, on the 3rd inst., in Section 3, read a paper on Micro-organisms and Alkaloids which render Food Poisonous. For the purposes of his address the author arranged diseased and otherwise unsound food into five classes:—(1) Vegetable food infected by fungi and other parasites, chiefly microscopic; (2) animal food containing entozoa or internal parasites; (3) animal food containing micro-organisms endowed with virulent properties; (4) animal and vegetable foods containing alkaloids generated during putrefaction; (5) the flesh of animals affected by specific diseases, the various *materies morbi* of which have not been isolated. Each of these divisions was discussed in detail, and the whole paper bore marks of careful research. Having already published some papers on the subject of the fitness of the flesh of animals affected with contagious pleuro-pneumonia, rinderpest, foot-and-mouth disease, and other maladies resulting from blood-poisoning, Dr. Cameron did not in his paper consider it. He, however, strongly advocated the systematic and skilful examination of food prepared or being exposed for sale.

On the 3rd inst. the business of the Congress was concluded by a lecture from Dr. Carpenter, the Chairman of the Council. He urged that stringent legislative measures should be passed to prevent the overcrowding of houses in the poorer parts of cities, and further recommended that in place of sewage being thrown into the sea and wasted it should be used for manuring. If the present system of sewage in London was continued a state of things would gradually be produced which would make the future sanitary history of the Thames somewhat similar to that which belongs to the Pontine marshes or the deltas of the great rivers of India. The 100,000,000 gallons of water fouled by the filth of London ought to be returned to the land whence the water came, and ought to be again filtered through the chalk hills, the Woking and other sand beds, or the barren acres of Surrey, Hants, Berks, and Oxfordshire, by which tens of thousands of cattle might be nourished, and millions of gallons of milk provided for the teeming population of the great metropolis of the empire.

SCHOLARSHIPS. — At the Middlesex Hospital Medical School, the science scholarship of the value of £50 has been awarded to Mr. J. Gordon; the entrance scholarship of £25, tenable for two years, to Mr. E. A. Falkner; the entrance scholarship of £20, tenable for two years, to Mr. H. B. Shepherd; and the exhibition of £20 to Mr. Alfred Clark.—At St. Mary's Hospital Medical School, Mr. R. T. Graveley and Mr. F. Lewis divided the scholarship in natural science of £105 open to students of Epsom College who are sons of medical men.

INTERNATIONAL MEDICAL CONGRESS.

PHYSIOLOGICAL SECTION.

Cheyne-Stokes' Breathing.

PROFESSOR MOSSO (Turin) has constructed an apparatus for registering respiratory movements in the healthy subject. This consists of a respirator applied over the mouth and nose connected with a delicate gasometer, and which can be worn by many persons during sleep without producing much inconvenience. An examination of the tracings which can be obtained showed a rhythmic variation of the same character as those seen in Cheyne-Stokes' respiration. These consisted of rhythmic variations, both in time and in quantity of air respired. Professor Mosso maintained that this condition, about which so much had been written, was a normal one, and could not be considered a pathological phenomenon at all.

Professor HAYCRAFT remarked that the experiment was not conducted under normal conditions, and that the resistance produced by the gasometer exhausting the nerve-centres of the respiratory muscles would, as in other cases of such depression, produce rhythmic variations of activity. A pathological condition may be a quantitative deviation from the normal; and if rhythmic variations should eventually be proved in normal breathing, the exaggeration of this seen, say, in a case of apoplexy might well be considered pathological.

Professor CHEVEAU suggested an improvement which might be made in the instrument of Professor Mosso, which would simplify it and diminish the resistance.

On the Action of a Secretion obtained from the Medicinal Leech on the Coagulation of the Blood.

Professor HAYCRAFT found that the leech secretes from its sucker and gullet a juice which prevents the coagulation of the blood, which therefore remains fluid within its body, and is difficult to stop when exuding from the wound after the animal is withdrawn. This may be extracted from the anterior part of the creature with water after dehydration in alcohol. The juice destroys the blood-coagulating ferment without killing the corpuscles. On invertebrate blood where the clotting is due to the welding together of the corpuscles it has no action. When injected into the veins of dogs or rabbits, the animals are thrown into a condition resembling hæmorrhagic diathesis; the blood withdrawn from the animal remaining fluid, and the smallest wound bleeding continuously on this account. It was suggested that in the case of transfusion of blood any chance of clotting could be prevented by injecting small quantities of the substance into the body of the person from whom the blood was afterwards to be taken.

THE INTERNATIONAL COLLECTIVE INVESTIGATION OF DISEASE.

A STATEMENT has been submitted by Dr. Isambard Owen, general secretary, in which the main object of the International Committee formed at the Copenhagen Medical Congress for the Collective Investigation of Disease is defined as follows. To widen the basis of medical science, to gather and store the mass of information that at present goes to waste, to verify or correct existing opinions, to discover laws where now only irregularity is perceived, to amplify our knowledge of rare affections, and to ascertain such points as the geographical distribution of diseases and their modifications in different districts. It will be its endeavour to place clearly before the whole profession the limits and defects of existing knowledge, as well as to stimulate observation and to give it a definite direction. The following is the proposed method. A subject having been selected, a person or persons of acknowledged authority will be asked to write a memorandum, in the form of a short essay, upon it. The memorandum will succinctly give the present state of our knowledge. It will also point out the directions in which further research may best be made; and, with this view, will suggest a few simple and definite questions upon the subject selected. The questions will relate to matters of fact, to be elicited by observation of cases, rather than to matters of opinion. The contemplated organisation will, it is hoped, in time enable the Committee to ask and collect answers to these questions from the profession at large wherever scientific medicine is studied or practised. It will be a further duty to examine, arrange, tabulate, and deduce results from the mass of observations thus collected, due credit being given to each contributor for the information he has furnished; and reports on the results of the several investigations will be laid before the International Congress at its next meeting at Washington.

OVER-PRESSURE IN SCHOOLS.

THAT the views which we have thought it our duty to enforce in connexion with the subject of over-pressure in elementary schools are accepted by those who, next to medical men, are best entitled to express an opinion on the point—viz., the school teachers—may be gathered from the following resolutions adopted at a meeting of the Executive Council of the National Union of Elementary Teachers on Saturday, the 4th instant.

Resolved:—"That this Executive Council, consisting of men practically engaged for years in the work of elementary education, and representing 13,000 elementary teachers in all parts of the country, endorses the general conclusions arrived at in Dr. Crichton Browne's report with respect to over-pressure in schools, and thanks him for the masterly way in which he has presented the facts of the case as known to teachers, and as established by communications received from teachers, managers, and parents of pupils in all classes of elementary schools in all parts of England and Wales. That this Executive Council has read with the greatest surprise the memorandum of Mr. Fitch on Dr. Crichton Browne's report, and distinctly affirms: 1. That teachers in Mr. Fitch's district and throughout the country declare that they find detention after school hours absolutely necessary to meet the requirements of the inspectors and secure a sufficient number of passes. 2. That examinations, instead of being tests of school work, have become, to a great extent, its one aim and guiding principle. 3. That the power to withhold children from examinations is not, and cannot be, effective to remove the over-pressure so long as the inspector is the sole judge, on the day of examination, of the reasonableness on which children are withheld."

In the face of testimony of this kind, what becomes of the charge of exaggeration brought against Dr. Crichton Browne by interested or ill-informed critics?

THE PROGRESS OF CHOLERA.

WITH the advent of cooler weather the number of fresh cholera cases in Italy is showing a decided diminution; the abatement being especially marked in Naples, Genoa, and Spezia, where the force of the epidemic had principally shown itself. There are still fluctuations; thus the latest news from the province of Cuneo relates to a notable increase in the number of attacks; and notwithstanding the general abatement which has taken place, the epidemic is still causing about 120 deaths a day in the localities concerning which statistics are officially published. The accounts from Venice are contradictory, but even if any cases of true cholera have occurred there, they have been but isolated ones. Rome still remains free from the epidemic.

In France, a few cases still occur daily at Toulon and Marseilles, and a new outbreak is reported from Oran; but elsewhere the epidemic still maintains signs of subsidence. In Spain, the provinces of Alicante, Lerida, and Tarragona continue to be the only ones whence cholera news comes; and in view of the late season, it may now be confidently hoped that the Peninsula will escape any such prevalence as has occurred in France and in Italy.

QUARANTINE AND INFECTED PORTS.

All arrivals in Algeria from Portugal are subjected to a quarantine of five days; the quarantine on arrivals from France has been reduced from five to three days.

The port and shore of the whole "Circondario" of Genoa

Digitized by Google

have been officially declared infected with cholera, and foul bills of health are issued. Vessels from Genoa are, on arrival at all non-infected Italian ports, subjected to ten days' quarantine if no sickness exists on board, and to twenty-one days if otherwise.

At Christiania the visitation of vessels from Great Britain, Holland, Belgium, and German North Sea ports has been abolished.

At Malta quarantine has been raised on arrivals from Sicily, from Turkish ports east of the Adriatic, and from ports in the Black Sea. Arrivals from Algeria are refused admittance.

The province of Oran and the port of Barcelona have been declared to be infected with cholera morbus.

In Greece all arrivals from Dulcigno and Antivari are subjected to five days' quarantine of observation.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

During the week ending the 4th inst., 5939 births and 3379 deaths were registered in twenty-eight of the largest English towns. The annual rate of mortality in these towns, which had declined in the six preceding weeks from 25·6 to 19·1 per 1000, rose again last week to 20·1. During the thirteen weeks of last quarter the death-rate in these towns averaged 22·8 per 1000, against 20·6 and 19·9 in the corresponding periods of 1882 and 1883. The lowest rates in these towns were 14·1 in Portsmouth, 16·6 in Brighton, 17·2 in London, and 17·3 in Plymouth. The rates ranged upwards in the other towns to 29·3 in Newcastle-upon-Tyne, 29·4 in Preston, 30·1 in Sunderland, and 31·4 in Halifax. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the six preceding weeks from 1314 to 611, further fell last week to 548; these included 281 from diarrhœal diseases, 68 from "fever" (principally enteric), 59 from scarlet fever, 54 from whooping-cough, 37 from measles, 37 from diphtheria, and 12 from small-pox. These diseases caused the lowest death-rates in Portsmouth, Plymouth, and Brighton, and the highest in Oldham, Blackburn, and Preston. The highest rates of mortality from diarrhœa were recorded in Blackburn, Bolton, and Preston; from measles in Preston and Bolton; from scarlet fever in Salford and Cardiff; and from "fever" in Salford, Birkenhead, and Blackburn. The 37 deaths from diphtheria in the twenty-eight towns included 21 in London, 4 in Liverpool, and 3 in Nottingham. Small-pox caused 10 deaths in London, 1 in Birkenhead, and 1 in Sunderland. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 471 and 536 in the two preceding weeks, was 533 on Saturday last; the new cases admitted were 106, against 65 and 129 in the two previous weeks. The Highgate Small-pox Hospital contained 22 patients on Saturday last, 7 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 159 and 162 in the two preceding weeks, further rose to 184 last week, but were 67 below the average. The causes of 76, or 2·2 per cent., of the 3379 deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Norwich, Wolverhampton, and in four smaller towns. The largest proportions of uncertified deaths were recorded in Huddersfield, Salford, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which in the two preceding weeks had been 20·8 and 23·0 per 1000, declined to 21·1 last week, and exceeded by 0·9 per 1000 the mean rate during the same period in the twenty-eight large English towns. In the Scotch towns the rates last week ranged from 13·4 and 16·0 in Perth and Edinburgh, to 23·9 in Dundee and 25·0 in Paisley. The 508 deaths in the Scotch towns included 56 which were referred to diarrhœal diseases, 20 to diphtheria, 17 to whooping-cough, 16 to scarlet fever, 14 to measles, 14 to "fever," and not one to small-pox; in all, 137 deaths resulted from these principal zymotic diseases, against 130 and 131 in the two previous weeks. These 137 deaths were equal to an annual rate of 5·7 per 1000, which was 2·4 above the average rate from the same diseases in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 51 and 52 in the two preceding weeks, further rose to 56, and included 20 in Glasgow and 12 in Dundee. The 20 deaths from diphtheria exceeded by 6 the number in the preceding week; 6 occurred in Glasgow, 6 in Dundee, and 3 in Edinburgh. The 17 fatal cases of whooping-cough showed a decline from recent weekly numbers, and included 5 in Edinburgh. Of the 16 deaths from scarlet fever, 9 occurred in Glasgow, where 11 of the 14 fatal cases of measles were also recorded. The deaths referred to "fever" showed a decline of 6 from the number in the previous week, and included 7 in Glasgow and 5 in Edinburgh. The 52 deaths referred to acute diseases of the respiratory organs in the eight Scotch towns were 13 less than the number in the preceding week, and were below those returned in the corresponding week of last year. The causes of 85, or nearly 17 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 26·6 and 30·2 per 1000 in the two preceding weeks, declined to 26·3 in the week ending the 4th inst. During the thirteen weeks of the quarter ending the 27th ult., the death-rate in the city averaged 25·4 per 1000, the rate during the same period being 20·9 in London and 17·0 in Edinburgh. The 177 deaths in Dublin last week showed a decline of 26 from the number in the previous week, and included 49 which were referred to the principal zymotic diseases, against 32 and 36 in the two preceding weeks; of these, 15 resulted from diarrhœal diseases, 8 from "fever," 7 from scarlet fever, 2 from diphtheria, 1 from whooping-cough, and not one from small-pox. These 49 deaths were equal to an annual rate of 4·9 per 1000, the rate from the same diseases being 2·2 in London and 4·4 in Edinburgh. The fatal cases of diarrhœa showed a further decline from those returned in recent weeks. The deaths referred to "fever," which had been 1 and 3 in the two previous weeks, further rose to 8 last week, and exceeded the number recorded in any week since April last. The 7 fatal cases of scarlet fever were 4 less than in the preceding week, and the deaths from diphtheria and whooping-cough also showed a decline from recent weekly numbers. Eight inquest cases and 3 deaths from violence were registered during the week, and 54 deaths occurred in public institutions. The deaths of infants and of elderly persons showed a decline from those returned in the previous week. The causes of 34, or 19·2 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Surgeon-General J. Irvine, of the Army Medical Department, having returned to Egypt and resumed duty as Principal Medical Officer of the Army of Occupation in that country, Deputy Surgeon-General Fox, who has been holding that position, has returned to Alexandria from Cairo, and taken over the post of Principal Medical Officer of the Alexandria Garrison.

ARMY MEDICAL DEPARTMENT.—Brigade Surgeon Wm. Henry Muschamp to be Deputy Surgeon-General, vice Thomas John Murphy, M.D., granted retired pay.

INDIA OFFICE.—The Queen has approved of the retirement from the Service of the under-mentioned officers of Her Majesty's Indian Military Forces:—Deputy Surgeons-General John Edward Tuson, M.D., and James Alexander Caldwell Hutchinson, M.D., of the Bengal Army; Surgeon-Major Rivers Mantell, of the Bengal Army.

BREVET.—The under-mentioned officers have been granted a step of honorary rank on retirement:—Deputy Surgeon-General John James Clarke, M.D., of the Bengal Army, to be Surgeon-General; Brigade Surgeons William Watson, M.D., and Theobald Mathew, of the Bengal Army, to be Deputy Surgeons-General; Surgeon-Major Ferdinand Odevaine, of the Bengal Army, to be Brigade Surgeon.

ADMIRALTY.—The following appointment has been made:—Fleet Surgeon William Graham, to the *Penelope*.

ARTILLERY VOLUNTEERS.—1st Gloucestershire: John

Digitized by Google

Hancocke Wathen, and David Samuel Davies, M.B., to be Acting Surgeons.

RIFLE VOLUNTEERS.—1st Dumbartonshire: John Maccallum Cameron, Gent., M.B., to be Acting Surgeon.—1st Pembrokeshire: Surgeon Edward Picton Phillips is granted the honorary rank of Surgeon-Major.

Correspondence.

"Audi alteram partem."

THE BEQUEST OF SIR ERASMUS WILSON.

To the Editor of THE LANCET.

SIR,—I observe that a proposition has been made by Sir Spencer Wells to devote a large portion of the magnificent bequest of Sir Erasmus Wilson to the formation of a Physiological and Pathological Institute. I sincerely hope that his proposition will be carried into effect. I cannot conceive of a more desirable object for the College to undertake than the foundation of an institution of this kind, one which would for ever perpetuate the College fame, and bring credit on all those who now have a voice in its councils. I believe also the proposal would receive the sanction and support of the whole profession. I have every reason to think so from the fact that, when three years ago the Association for the Advancement of Medicine by Research was founded, all the leading and most distinguished men in the profession came forward to maintain in the strongest terms the absolute necessity of providing some means for the furtherance of our science and art by more precise methods. The earnestness of these gentlemen was shown by the readiness with which they opened their purses to aid in the object which they had at heart. With all their liberality, however, the private subscriptions of medical men could afford but scanty means for the development of so large and important an object. Our Colleges have no funds to undertake it, and Government will not assist. It is only therefore by the liberality of private individuals that any hope can be entertained of rearing an institution devoted to pure science. The opportunity has now arrived when this can be done; an opportunity which may not occur again for another age, and one which now taken advantage of will surround the president with glory. A learned body has it in its power to found an institution to be devoted to pure science, untrammelled by any conditions to mar its usefulness. I feel sure too that such a foundation would have been quite in accord with the feelings of the bequeather.

That interest in biological work has not departed from us is proved by the popularity of Professor Michael Foster's laboratory; but we want something still greater, something more national. At the present time a large number of workers are obliged to seek their means of investigation abroad, and, what is more lamentable, a considerable number of young men of scientific tastes, to be met with in all our medical schools, are forced to relinquish their good intentions for lack of opportunity. I do therefore trust Sir Spencer Wells's proposal will become a reality; there is a crying necessity for an institution where physiological, pathological, and therapeutical research can be carried out, and the College has now in its hands the power to rear such a one in our midst. This will indirectly bring with it large practical advantages, and the College therefore will also have the satisfaction of knowing that it is acting as a public benefactor.—I am, Sir, your obedient servant,

Grosvenor-street, W., Oct. 1884. SAMUEL WILKS.

STOPPING TEETH AT GENERAL HOSPITALS.

To the Editor of THE LANCET.

SIR,—Will you permit me to bring before the profession by means of your journal a subject which to my mind is of the most vital importance to the public—viz., that general hospitals should make provisions for the stopping of teeth? How many instances do all of us see where good teeth are sacrificed merely for the want of proper attention at the commencement of the decay, to say nothing of the innumerable instances where teeth are extracted daily from patients who attend the various hospitals simply because the operator is aware of the fact that such patients have not the means to have their teeth stopped, and thus he extracts them rather than allow the sufferers to be in continual pain. Now what does this mean? That healthy young persons of poor circumstances are forced to sacrifice their teeth, and thus when they reach advanced age their health is broken down by chronic indigestion and the very many other maladies allied thereto, to say nothing of the loss of nature's gift, a good set of teeth, which is of no small matter to one's beauty, especially to marriageable young women. As general hospitals take up every other branch for the relief or cure of diseases which flesh is heir to, why not this most important branch? I feel confident that if the treatment to which I refer were once to be established, we should not have the slightest trouble in carrying out the good work, without experiencing any difficulty or incurring expense, so to say, to already overtaxed institutions. I am certain there would always be double or treble the number of students who would be delighted to fill the office of dental dresser for fixed periods, as in the other departments of hospitals; indeed many of such dressers, who intend following dentistry, would be receiving instruction at the same time at the dental hospitals; but even those who do not intend doing so would take a delight in the work merely for the sake of the experience in acquiring the art of stopping teeth. I devoted some time, when a student, to acquiring the knowledge of extracting teeth under the supervision of the appointed dental surgeon of the hospital to which I belong; and, although I do not follow dentistry, even in its simplest forms, I feel the immense advantages I have gained in being able to diagnose, I may say, at a glance the pathology and necessary treatment which ought to be adopted in different maladies of the mouth—a knowledge which I feel sure I should not have possessed had I not had some experience in such matters.

By way of conclusion, I may mention that only recently one of my domestics asked leave to go to a hospital for the purpose of having two teeth extracted, as she could not afford to have them stopped, and the dental hospitals (Leicester-square and Great Portland-street) were so far distant. "Besides, everyone cannot go there!" On looking at the teeth I found that they were the two anterior lower molars, and as I considered them not too far decayed to be stopped, I sent her to a dentist. The result is that she has thus saved two useful teeth, which will, in all probability, last for years.—I am, Sir, yours truly,

Baron's Court, S.W. R. FITZROY BENHAM.

LUNACY LAW AGITATION AND SUICIDE; THEORY *v.* COMMON SENSE.

To the Editor of THE LANCET.

SIR,—I have to express my thanks for your insertion of my letter in your last issue, and for having acceded to my request that you would favour me with your judgment upon the facts related. I trouble you again with reluctance, but the matter seems to me important enough to justify further discussion. Your verdict is that "the fault was obviously that of the friends," and you remark that "it is nothing to the point that the husband was eighty." I cannot have made clear what I wished chiefly to emphasise—viz., that the patient had no friends. The age of the husband is very much to the point, because, by reason of his age, he was unable to cope with his wife in her excitement. But, leaving this case for a moment, what has hitherto been the course usually pursued by a medical man whose patient, being attacked by insanity, requires treatment such as in his judgment cannot be pursued at home? He recommends treatment in an asylum. Asked to advise what asylum, he advises. He explains the requirements of the law; he sees the necessary forms gone through; and if, as so frequently happens, the case is of a nature to make personal action on the part of the patient's friends unwise, he recommends application being made to the asylum superintendent to select some one from his staff to accompany the patient from home. What could be more in accordance with common sense? with common humanity? What could be less open to the charges of "fussy interference" and "discreditable touting"? As to the law of the matter, the Lunacy Acts say nothing. They tell us that such and such conditions having been fulfilled, the superintendent may "receive"; they are silent as to whether he may or may not "send for" the person to be admitted

Digitized by Google

The theory just now appears to be that he may not, this theory being founded on remarks made by the judge in the case of Weldon *v.* Semple. Hence (to return to the case which prompted my first letter) because the theory happens to be what it is, nobody felt at liberty to act. Common sense went to the wall; theory triumphed; but the patient died.

I am, Sir, yours faithfully,
H. J. MANNING.

Laverstock, near Salisbury, October 7th, 1884.

*** Our correspondent does not seem to see our point. It is not for a medical practitioner to meddle in the carrying out of his recommendation. He gives advice; with that his function ends. It is neither right nor wise to attempt to carry his precepts into practice. He should decline to do more than counsel; it is no affair of his whether the patient has friends or not. Medical men should limit their interference to the simple task of advising. They do not act wisely if they go further.—ED. L.

"OVER-PRESSURE IN SCHOOLS."

To the Editor of THE LANCET.

SIR,—Dr. Fergus has been medical officer to Marlborough College for more than a quarter of a century, and has a right to speak with the authority of a long experience of the diseases incident to school life; but some facts of his own previously published seem to stand in the way of the accuracy of his view that boys at Marlborough enjoy better health and develop in vigour more during term time than in the holidays. For example, Dr. Fergus reports the death of a boy from so-called spontaneous septicæmia, whose illness began in December—i.e., the last month in the third term of the year. The head master of Marlborough reports in *The Times* another death following an ambiguous illness beginning on July 14th—i.e., again the last month in the longest term of the year. I can find no record of similar deaths at the beginning of term, when, according to Dr. Fergus, schoolboys are more out of health than at the end. Other deaths have occurred at Marlborough, the exact dates of which I have no record at hand; but Dr. Fergus could probably supply the dates of these more readily than I could. There appears also to have been a death-rate at Marlborough equal to from two to three per cent. of the cases of scarlet fever, which is, as far as my observation goes, in excess of the death-rate among patients in private practice of the same age and class as the boys at Marlborough. These facts appear to me to be inconsistent with Dr. Fergus's view that health is better preserved and life more secure at school than at home under parental care.

If more evidence is necessary to prove the exhausting influence of school life, it would be obtained by a study of the group of head masters of our public schools. When they met at Wellington College in conference I saw them photographed in group in front of the College, their faces

"Sicklied o'er with the pale cast of thought."

Of some sixty masters I could only pick out three who looked ordinarily healthy, and only one with a face in the least rubicund, and this genial countenance might have been seen in a good likeness of him in the Royal Academy of this year. Anyone interested in this group might obtain a copy of Bishop, Bookseller, Wellington College. It is very expressive.

I am, Sir, yours truly,
J. G. BARFORD.

Wokingham, Oct. 6th, 1884.

CATHETER FEVER (?)

To the Editor of THE LANCET.

SIR,—Much interest was recently excited in this subject by the address of Sir Andrew Clark and subsequent discussions at several of the Medical Societies. A case recently came under my notice which impressed me much, the details of which, so far as known to me, are as follow:—On September 21st I was requested to visit a patient, whom I found to be a man about fifty years of age, who had previously served in the army. There was a history of long-standing stricture, for which the patient had been treated in the Royal Infirmary of Edinburgh and the Glasgow Western Infirmary. Without much difficulty I passed an elastic catheter, which, as there was coarctation of the urethra, the patient retained in the bladder for about eight hours. On my subsequent visit on the 24th the patient complained of a good deal of pain in the region of the bladder, and on this account, and as there were no urgent symptoms to justify it, no instrument was passed, but bromide of potassium and tincture of buchu were ordered internally. The patient was again seen on the 27th, and his condition was much as before. Morphia suppositories were ordered, with milk *ad libitum*, and a metallic instrument was passed, and at once withdrawn. The last drops of urine were slimy and tenacious, indicating vesical inflammation. On the 29th, two days subsequently, the condition of the patient seemed alarming; the pulse was weak and irregular, and the tongue was dry, as in typhoid fever, while since my last visit vomiting and retching had hardly ceased. I should have mentioned that on the 27th vomiting was also complained of, and that small doses of hydrocyanic acid and solution of bismuth were therefore given, but had no effect. On this occasion two teaspoonfuls of brandy were ordered with the milk as formerly, and the use of a warm sitz-bath was enjoined. The urine was scanty and high coloured. On my visit the next day I found that the patient had died about 10 A.M. Is this a case of catheter fever? or, is it a case of nephro-vesical fever independently of catheterism? I call to mind in this relationship the death of a medical friend well known in this city, and I confess that unless these cases be of a like nature to those described by Sir Andrew Clark and others, the pathology is to me perplexing.

I am, Sir, yours faithfully,
D. CAMPBELL BLACK.

Glasgow, Oct. 6th, 1884.

PRESTON MEDICO-ETHICAL SOCIETY.

To the Editor of THE LANCET.

SIR,—We beg to forward you a copy of the enclosed resolution, passed at a general meeting of the above Society, held on September 24th, 1884.

We are, Sir, yours respectfully,
JOHN HOLDEN, } Hon. Secs.
J. J. BYRNE, }

Oct. 4th, 1884.

"Resolved that the Preston Medico-Ethical Society (and also requesting kindred Societies to) petition the General Council of Medical Education and Registration to obtain a clause in the next Medical Act Amendment Bill (or as a separate Bill) to the following effect:—'That whereas large numbers of Her Majesty's subjects are to their great injury misled and deceived by the advertisements offering medical and surgical advice by unqualified persons; be it therefore enacted that all such persons not having duly obtained a diploma, degree, or licence from any of the qualifying bodies named in Schedule A of the Medical Act, 1858, be deemed liable and subject to the penalty or penalties claimable under the Fortieth Section or Clause of the said Medical Act, 1858.'"

"BICYCLE RIDING AND PERINEAL PRESSURE: THEIR EFFECT ON THE YOUNG."

To the Editor of THE LANCET.

SIR,—After reading Dr. Herschell's letter in your last issue, I was not a little surprised to find that gentleman's name in the list of candidates for admission to the Cyclist Touring Club, published in this month's *Cyclist Touring Club Gazette*. Since Dr. Herschell "quite agrees with everything Dr. Strahan has said," and is convinced "that bicycle and tricycle riding will produce stricture of the urethra," it can hardly be that he is willing to run the risk of exemplifying in his own person these dire results of this "most healthful form of exercise." Possibly, however, Dr. Herschell has found some method of obviating the pathological results of cycling, and, if so, will doubtless take an early opportunity of bringing it before the notice of his fellow-cyclists.

I am, Sir, yours truly,
J. W. BATTERHAM, B.S. Lond.
(Member of C. T. C.)

General Hospital, Wolverhampton, Oct. 2nd, 1884.

*** Other letters on the above subject are unavoidably held over till next week.—ED. L.

HOSPITAL ABUSE AT BIRMINGHAM.

To the Editor of THE LANCET.

SIR,—Can you afford me space for a word or two on this subject? We hear a great deal about the prevalence of the abuse of hospitals in London, but I humbly think if observers would let the profession know how much it abounds in the Midland metropolis it would help forward the movement for reform. I have not great means of observation, but in my practice I have frequently seen cases which go a long way to prove that the yearly subscription to hospitals is not a charity but an investment, for which return is expected. The authorities of the hospitals scatter broadcast through our churches, &c., at stated periods, blank schedules crying loudly for monetary subscriptions, and an intimation that the donor of a certain sum will have so many notes given him in return. These "notes" are distributed indiscriminately, and at the hospital no questions are asked. The bearer gets advice and medicine gratis "till the note expires." Now, to my certain knowledge, many people well able to pay the moderate fees of the private general practitioner go regularly to the hospital in this way. I go into houses daily, well furnished, several grown-up members of the household in constant work, where they tell me I am called in an emergency, "as they are hospital patients," or their "note" is expired, and they have failed to find another "note."

I saw a patient recently to all appearance quite comfortable as regards means. She suffered from liver disorder and dyspepsia. She had a box of lactopeptine and a mixture obtained from the "dispensary." Surely some reformers of the right sort are forthcoming to stop the traffic.

I am, Sir, yours faithfully,

Sept. 1884. FIAT JUSTITIA.

LIVERPOOL.

(*From our own Correspondent.*)

OPENING OF THE WINTER SESSION OF UNIVERSITY COLLEGE.

THE opening of the winter session of the Liverpool University College took place on Saturday, under most favourable auspices. Additional interest attached to the proceedings in consequence of its being the fiftieth anniversary of the School of Medicine, which was organised in 1834. Lord Derby presided, and presented the prizes to the successful candidates with his usual courteous ability. The address of Professor McCann was a most admirable production, delivered with graceful eloquence, and was listened to with deep attention, the only interruptions being the frequent bursts of well-merited applause. Professor Rendell, the Principal, in his report, gave a most encouraging account of the progress of the College. In the evening the annual dinner took place at the Adelphi Hotel, under the presidency of Professor Rendell. Eighty-four gentlemen attended, and among the guests were the Mayor (Mr. Thomas Holder), the Chairman of the Dock Board, and several members of the Royal Infirmary Committee. The professors, medical staff, and students were well represented.

INFECTIOUS DISEASES HOSPITAL.

Although the difficulty as to a temporary hospital for infectious diseases has been happily overcome, another difficulty has sprung up in its stead. Owing to the persistent action of two members of the City Council it has become compulsory for the latter to provide at once a permanent infectious diseases hospital. As usual, there is the difficulty of selecting a site which shall please everybody and displease nobody. A site had been recommended to the City Council by the Health Committee. It is situated in Wavertree-park, a little beyond the eastern boundary of the city, and has many recommendations, chiefly those of proximity and easy access. But it has the objectionable propinquity to the works of the London and North-Western Railway, the incessant noise of which both by night and day cannot but be prejudicial to the recovery of fever patients. At a meeting of members of the profession on Tuesday night in the Medical Institution the following resolution was passed: "It is the opinion of this meeting of the medical profession of Liverpool and its neighbourhood that, whatever reasons may be advanced for or against the neighbourhood of Edge-lane Hall as a site for a fever hospital, its close proximity to the extensive system of rails of the London and North-Western Railway must be considered an insuperable objection to its adoption."

THE DEAD-HOUSE, PRINCE'S DOCK.

The Liverpool side of the river Mersey occupies some miles in length, and of this the Prince's Dock is the centre. Many years ago a "dead-house" was erected by the Dock Board to receive the numerous bodies which from time to time are washed up by the tide or found floating in the river and docks. Such was the original intention, but practically it is the dead-house for the whole city, receiving bodies from the Leeds and Liverpool Canal, and from all parts within the borough boundary. In it many post-mortem examinations are made, and a faithful record of all these would add considerably to the literature of medical jurisprudence, especially as relating to infanticide and death from drowning. In spite of efforts made both by the present and late medical officers of health, it still unfortunately happens that the dead-house is a very imperfect and most unsuitable structure, in which surgeons have to perform their important duties amidst surroundings inconvenient, unfavourable, and thoroughly uncomfortable. It is high time that in such a city as Liverpool at least one proper mortuary and post-mortem room should be erected in a convenient situation.

THE DANGERS OF PARAFFIN LAMPS.

On Monday night four persons lost their lives through the upsetting of a paraffin oil lamp, which set fire to the staircase and kitchen furniture of the house, the smoke from which suffocated the inmates of the upper rooms. The bodies were subsequently recovered in a very charred state, and removed to the Prince's Dock dead-house. On Tuesday a woman and her son were taken to the Northern Hospital suffering from burns through the upsetting of a paraffin lamp. The son's injuries were fortunately but slight, and his mother is progressing favourably.

THE DISSECTING ROOMS.

Dr. Barron, the Demonstrator of Anatomy, has already secured ten subjects on which upwards of sixty students are engaged dissecting. It is hoped that the class will already be largely increased by new entries. The other classes have all commenced, and are well attended.

THE MEDICAL INSTITUTION.

The President of the Medical Institution (Dr. Robert Gee) will inaugurate its opening on Thursday night by an address on the history of the institution since 1864. Anatomical and other exhibits, and micro-photographs shown by the oxy-hydrogen lantern, will contribute to the interest of the occasion.

Liverpool, Oct. 8th.

NEWCASTLE-ON-TYNE.

(*From our own Correspondent.*)

NEWCASTLE COLLEGE OF MEDICINE: THE NEW SESSION.

THE winter session of the Newcastle College of Medicine in connexion with the University of Durham was opened on the 1st inst., and the proceedings were very interesting. The Dean of Durham made some happy remarks during the distribution of the prizes. In the absence of Dr. Heath, the president of the College, Dr. C. Gibson opened the meeting, and stated that during the past year 192 candidates had presented themselves for examination, and of these 107 had satisfied the examiners. During the year 200 students had been enrolled in the books of the College of Medicine, and at the autumnal examinations just concluded 49 candidates presented themselves. Dr. Gibson next pointed out the pressing need which existed for adequate premises for the College, and it is satisfactory to note on this point that our municipal authorities have lately conceded this necessity, and there is now a good prospect of the Medical College and the College of Physical Science having a home under one roof and in a building worthy of the city, and of the visit of the Prince of Wales, which event it is

Digitized by Google

proposed to commemorate under the name of the "Royal Albert Edward United College."

THE SANITARY CONDITION OF ALNWICK.

Dr. Spear, the inspector appointed by the Local Government Board, has made a complete inspection of those portions of the town where insanitary conditions were stated to prevail, and the local papers state that a thorough condemnation of the sanitary condition of the portion inspected by him was the text of his remarks at the Local Board, and this although some ancient abuses in the ducal town were stoutly defended. Dr. Spear's report to the Local Government Board is likely to lead to very much needed reforms.

THE COMING WINTER AND THE WORKING CLASSES.

The approach of winter is looked forward to with some apprehension, owing to the want of employment in the North. At Sunderland there is already very great distress, where 30,000 persons are said to be out of employment. Durham also is suffering, and at the east-end of our city there is much distress. This is the locality depending so much on shipbuilding and its allied trades. Our mayor (Mr. Newton, Surgeon), fully alive to the exigencies of the working classes, has decided to call a town's meeting, and some very handsome subscriptions have been sent in, notably one of £100 from Mr. Joseph Cowen, our senior M.P.

THE NEW EYE INFIRMARY.

The Duke of Northumberland has consented to lay the foundation stone of this new hospital on Monday next, the 13th.

PENNY DINNERS IN NEWCASTLE.

The penny dinner project first mentioned in the North by the Rev. Moore Ede, the rector of Gateshead, has attracted much attention all over the district, and in various places steps are being taken to establish the system. A commencement was made on a large scale in Newcastle last week by Mr. Anderson of this city, who has opened rooms with accommodation for 1000 persons. The prices for adults range from one penny to fivepence. For the penny a basin of good soup and a large piece of bread are supplied, while for fivepence a repast of three courses is given of good, wholesome, and satisfying food. The Mayor of Gateshead pointed out that the prospect of profit depended very much on the number of those who partook of the dinners, but that 1000 dinners could be supplied at a surprisingly small sum, and still leave a margin.

WALLSEND DEATH-RATE.

A medical writer in one of our daily newspapers draws attention to the very high death-rate prevalent at Wallsend, 39 per 1000 at present, which he fears is likely to increase. He points out very forcibly that although the population has trebled, the "old drainage system," if it can be dignified by terming it a system, still prevails, and that the mortality now is higher at Wallsend than that reached at Sunderland when THE LANCET sent down a commission to inquire into and report upon the sanitary condition of that borough. The writer calls for a Government inspection, and in view of some of the facts already brought under your notice in the preceding portion of this letter as to the condition of the working classes on the Tyne, his demand would appear to be reasonable and opportune.

Newcastle on-Tyne, Oct. 7th.

GLASGOW.

(From our own Correspondent.)

OUTBREAK OF ENTERIC FEVER.

IT is satisfactory to be able to report that the outbreak of enteric fever which occurred in the three large hospitals in this city seems to have been checked, its course, and its subsidence when its cause had been discovered and removed, being such as to support the view taken of its causation in Dr. Russell's report.

SMALL-POX.

One case of supposed small-pox was admitted to the small-pox hospital during the past fortnight, but was dismissed in a few days, having turned out to be a case of skin disease.

THE SMOKE NUISANCE.

The smoke nuisance was under discussion lately by the Town Council. Anyone who is familiar with Glasgow will be aware that to say that its atmosphere is murky and loaded with smoke to a degree highly prejudicial to health is to state the matter very mildly. The Council seem to think that the question is not one to be lightly meddled with. One magistrate, who has to try "smoke cases" not unfrequently, "made bold to say that hardly any one of the plans proposed for consuming smoke was of much use. As a smoke-producer he would not be dictated to by the Health Committee, or by any scientific man, as to what he was to do in this matter. He would conduct his business and consume his smoke as best he could, and the duty laid upon the Town Council was to keep him from making smoke the best way they could." Another councillor held that "the city lived by smoke, and why should they kill the goose that laid the golden eggs?" When sentiments like these are entertained by our local rulers and law administrators, there can be little wonder that our Smoke Act is practically a dead letter in Glasgow.

The names of the Earl of Stair and the Earl of Rosebery have been mentioned in connexion with the vacant office of Chancellor of the Glasgow University.

I understand that no fewer that 150 candidates are presenting themselves for the third professional examination for medical degrees at Glasgow University.

The Western Medical School in Glasgow is not in a very flourishing condition. Three of its lecturers have resigned their posts—those on materia medica, chemistry, and medical jurisprudence.

ITALY.

(From our own Correspondent.)

HAVE Italian pathologists, in considering the factors of cholera, taken due note of the habitual defect of chloride of sodium, or common salt, in the daily food of its victims? That essential constituent of healthy blood appears in excessive quantities in the choleraic dejecta; and its withdrawal from the system, by diminishing the fluidity of the circulation, contributes to the consequent stasis and ultimate collapse. It is reasonable to assume that cholera patients who have not been denied the normal proportion of chloride of sodium in their diet, and have therefore the due amount of it in their blood, should, when the hydrorrhagia sets in, be better able to afford the saline loss and to maintain a longer fight with the disease than those in whose daily meals it has been habitually deficient. But this latter condition—defect of chloride of sodium in the daily food, and therefore in the system—is precisely that in which the lower population of Italy is generally found. Common salt is a Government monopoly throughout the Italian Peninsula. As such it is sold, like tobacco, at a price which millions of the poorer classes cannot afford. They therefore accustom themselves to do without it or only occasionally to indulge in it, to the serious injury of their vitality or resisting power to disease. It is a curious coincidence that the countries in which cholera is endemic, like India, or in which it easily effects a footing, like Arabia, are precisely those where the food of the people—rice mainly—is generally taken without the due proportion of common salt. The connexion between this "error in diet" and the liability to succumb to cholera is well worth the consideration of the hygienists of Italy; while Italians themselves, instead of rising in mutiny against the communal physicians as if these were trying to poison them, might more profitably agitate for the repeal of the salt tax, which places an essential constituent of healthy food beyond their reach.

In confirmation of the absolute necessity of maintaining the due proportion of chloride of sodium in the system as the condition of recovery from cholera, the success of hypodermoclysis in treatment may again be referred to. One of the most conspicuous cases of its efficacy in Naples has been that of the son of the well-known musician and composer, the *maestro* Petrella, on whom when in the stage of apparent death, and when about to be consigned

Digitized by Google

to the undertaker, the operation was practised, according to the method of Cantani, with complete success. True, the operation has in many cases disappointed expectations, but on inquiry it has been found that in these it was performed unskilfully or at an inopportune time—that is to say, when the process of intestinal transudation was still going on, and when the solution of carbonate of soda and chloride of sodium was draining away almost as fast as it was injected. As to other methods of combating the disease, the profession seems settling down to the opinion of Stefanoni, as conveyed in the following words:—"The only cure, rational and preservative, of cholera is to check the diarrhœa on its first appearance. In a country invaded by the epidemic, no abnormal intestinal movement ought ever to be neglected. From its first declaring itself, the patient should be put to bed, since absolute repose, combined with astringent treatment, is the only available means of checking the serous flux of the intestines. Fifteen drops of laudanum in a few teaspoonfuls of peppermint-water are the one efficacious medicament I have seen used in the primary diarrhœa; and this, it cannot be too often repeated, if attended to at once, on its first appearance, is certainly curable, while rigorously keeping the recumbent posture in bed, regulating the diet, and drinking at frequent intervals and in small sips acidulated beverages like lemonade, or, if there be febrile heat, sucking from time to time little pieces of ice. To the arrest of the premonitory diarrhœa, which by common consent, if treated in time, is perfectly tractable, are reduced all the pretended cures of cholera—cures vaunted by so many as specifically due to the most various remedies. Once the patient has neglected the treatment of this primary stage, medicine can do little more than confess her impotence, since, by the consensus of all practical physicians, there is nothing to do but await the setting in of an extremely uncertain reaction."

Genoa has not escaped the epidemic, after all, though its incidence has been much less violent than at Naples. This has been mainly due to the more robust, better fed population of the Ligurian seaport, to the complete absence of panic, and to the prompter treatment of the premonitory diarrhœa. The Committee of the Red Cross, headed by the Syndic Signor Podestà, and reinforced by the most prominent among the citizens, including many ladies of high position, has done yeoman's service in limiting and attenuating the force of the malady. One effective stroke of hygienic strategy by which the invader was kept at bay was the stoppage of all water-supply to the town from the Scrivia torrent, after this was found to have been infected by the cases that had occurred at Busella. Deplorable to relate, after all the experience so dearly won at Spezia, the Scrivia water furnished by the Nicolay Company had been allowed to be contaminated by the washing of the linen of the cholera patients of that neighbouring township! And the Nicolay Company, rather than suffer pecuniary loss, had withheld the knowledge it possessed as to this contamination! But purer water has now been introduced; the sick-list and death-rate are manifestly on the decline, and numerous families who were preparing to join in a general stampede are remaining quietly in their homes.

Rome, to the great credit of the provisional syndic, Duke Leopold Torlonia, maintains her wonderfully clean bill of health, and with it the calm of the entire population. Her water-supply, long known to be the finest for purity and abundance in Christendom, has again been subjected by Professor Mauro to chemical analysis, and again with invariably satisfactory results. The Acqua Marcia, the Acqua Vergine, the Acqua Felice, and the Acqua Paola have all been proved to be perfectly limpid; to contain no organic matter of animal or other origin; to leave, when evaporated, a residue of not more than 50 grammes to the 100 litres of water; and to yield from this residue not more than thirty grammes of *carbonate terreux*, or than four grammes of magnesia. The best of the four are the Acqua Vergine and the Acqua Marcia. "We know," says Professor Mauro, "that the composition of the water has an influence on the development and the multiplication of some harmless microscopic organisms, but we are in absolute ignorance of what favours or counteracts the hurtful organisms, because we do not know their biology; we are ignorant, in fact, whether the water transmits them intact or feeds and develope them."

The literary "hit" of the hour is Professor Angelo Mosso's article in the *Nuova Antologia* on the "Precautions against Cholera and Quarantine"—a brilliant exposure of the futility of those mediæval safeguards on which Italy—not much to her credit and greatly to her cost—has, for the last time, let us hope, placed such implicit reliance.

Rome, Sept. 29th.

Medical News.

APOTHECARIES' HALL. — The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Oct. 2nd:—

Angior, Thos. Matthews, Oriel-road, Bootle, Liverpool.
Brighouse, Herbert William, Fortess-road.
Sykes, Thomas Hindle, Hoghton-street, Southport.
Thompson, Edward Egerton, The Square, Tenbury.
Woodforde, W. Sidney Ridout, Oakbank, Spencer's Wood, Reading.

The following gentlemen also on the same day passed the Primary Professional Examination:—

Harry Gravely, University College Hospital; Archibald Thomas, Middlesex Hospital.

Passed and received a certificate on Sept. 25th:—

Santi, Philip Robert William, Doughty-street.

ROYAL UNIVERSITY OF IRELAND. — The following have obtained the degree of M.B. and the diploma in Obstetrics:—

BACHELOR OF MEDICINE.—W. Frederick Bailey, Patrick Blackall, Arthur Blackwood, Fredk. James Burns, George Clarke, John N. Corbett, Patrick Cotter, Warren Crooke, James Ferguson, Joseph Guisani, Charles Graves, Edward Greene, Chas. Hayden, Peter Horkan, Samuel Hunter, Hugh Lewers, Marcus Loudon, James McAvoy, Nicholas McDonnell, Joseph McKay, Morgan McSwiney, Edward Magennis, James Magner, Donald Martin, John Moore, Hugh Morrison, Cornelius O'Doherty, Michael O'Halloran, Patrick O'Hara, Joseph Prendergast, Fred. Sinclair, Alfred Smith, Patrick Soraghan, E. Starling, George Tate, Wm. Wadsworth, Geo. Waters, George Wynne.

The following passed in the upper pass division, and those marked with an asterisk will be admitted to a further examination for Honours:—

*Wm. Bartley, Robert Carter, M. Connery, Charles Cooke, *J. T. Daly, Charles Elliott, Thomas Frisell, *Thos. Grainger, *Benjamin Hosford, *John Kearney, *Philip McCarthy, *Robert Macnamara, *James Morwood, *Denis Sheehan, *William White.

DIPLOMA IN OBSTETRICS.—P. Blackall, A. Blackwood, John Bullen, P. Cotter, C. R. Elliott, J. C. Ferguson, J. Guisani, T. Grainger, S. Hamilton, B. Hosford, John Kearney, H. Lewers, J. McAvoy, P. McCarthy, N. McDonnell, J. F. Magner, J. Morwood, Cornelius O'Doherty, M. O'Halloran, D. Sheahan, A. J. Smith, E. Alfred Starling, William White.

IMPORTANT concessions as to reduction of time on duty have been made to the employés on the Brighton Railway.

FEMALE NURSES FOR THE ROYAL NAVY.—The Admiralty have passed important regulations for the female nursing staff, which is to some extent to supersede the present staff of male nurses at the Royal Naval Hospitals.

VACCINATION GRANTS.—Dr. Guy (Norwich) and Mr. J. H. Hughes (Ombersley district of the Droitwich Union) have received the Government grant for successful vaccination in their districts.

AT the last meeting of the City Commissioners of Sewers, the proposition to increase the salary of the medical officer of health, Dr. Sedgwick Saunders, from £900 to £1100, was carried by a majority of forty five against sixteen.

THE beautiful Hall of the Knights, Copenhagen, where the king recently entertained the Medical Congress, was unfortunately totally destroyed by fire on the 3rd inst. The entire palace has been almost consumed by the conflagration.

THE HOWARD ASSOCIATION.—This Association has, in response to a request made by the president of a Congress on Prisons, Pauperism, &c., to be held at St. Louis, Missouri, U.S.A., on the 13th inst., forwarded an address in which are discussed some of the principal questions in which the English Association and the American Congress are special interested.

A WATER FAMINE.—East Lutton, a village on the Yorkshire Wolds, near Driffield, is stated to be entirely destitute of a supply of water, and the villagers have to fetch it from another place more than a mile away. At Timber the inhabitants are reported to be almost entirely dependent upon the village pond, which is fouled by animals.

Digitized by Google

SUICIDE OF A SURGEON.—An inquest was held last week by Mr. Collier on the body of John Lamond Hemming, M.R.C.S., L.R.C.P., who up to his death practised in Finsbury. Evidence having been given as to the discovery of the body, and Dr. Evans having deposed to the cause of death—i.e., poisoning by prussic acid—the jury returned a verdict "that deceased committed suicide while labouring under temporary insanity."

SANITARY ASSURANCE ASSOCIATION.—The Council of this Association has resolved to present to the free public libraries of the country copies of Mr. Mark H. Judge's "Sanitary Arrangements of Dwelling Houses; Notes in Connexion with the Sanitary Exhibits of the International Exhibition," recently published by the Sanitary Assurance Association, of which Mr. Judge is the surveyor.

HEALTH EXHIBITION, DUBLIN, HOSPITAL FETE.—On Saturday last, the fête in aid of the Dublin hospitals was held; it was a decided success, the attendance being very large, and the amount received must have been considerable. During the evening there was an ambulance demonstration, and a distribution of bronze crosses by Sir R. Rawlinson awarded to members of the Dublin police.

BOARD OF CONTROL OF IRISH LUNATIC ASYLUMS. This board has been reconstituted, and the following now comprise its members:—Major-General Sankey, John Nugent, George Hatchell, William R. Le Fanu, and Samuel Usher Roberts. These will act as commissioners for general control and correspondence, and for the superintending and directing the erection, establishment, and regulation of asylums for the lunatic poor in Ireland.

DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY.—At a meeting of the committee of management of this institution on the 4th inst., it was stated that 1063 in-patients and 148 out-patients had been admitted during the three months which ended the 30th ult., being a large increase on the number admitted during the corresponding quarter of 1883. The receipts from all sources show a general increase as compared with the corresponding period of 1883.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The first meeting of the twenty-ninth session of this Society was held on the 3rd inst., when an address was delivered by the President, and the following were chosen office bearers:—President: Mr. John Marshall. Vice-Presidents: Dr. R. Carrington and Mr. C. H. Hartt. Council: Mr. A. L. Bowen, Mr. J. Brindley-James, Mr. G H. Cable, Mr. F. Carson Fisher, Dr. A. Forsyth, Mr. J. Hammersley, and Mr. F. Moon. Treasurer: Dr. Prior Purvis. Secretary: Mr. H. W. Roberts. Librarian: Dr. J. B. Saundry.

TEMPERANCE LECTURES.—The Committee of the Women's Union of the Church of England Temperance Society have arranged for the delivery of four lectures during November—viz., by Dr. E. Symes Thompson, on the 8th and 15th, on Temperate Teaching on Temperance, and the Causes and Preventive Treatment of Inebriety; and by Dr. Oliver Leeson on the 22nd and 29th, on Alcohol in Health, and on the Formation of Temperate Habits in Early Life. The lectures commence at 3 30 P.M., the first two being delivered at 83, Lancaster-gate, and the remainder at the Vestry Hall, Kensington High-street.

NEW BRANCH OF THE BRITISH DENTAL ASSOCIATION.—A meeting of dental practitioners took place in Birmingham, on Sept. 20th, at which it was resolved to form a Society, to be called the "Central Counties Branch of the British Dental Association." Dr. Waite of Liverpool presided. The laws of the Midland Branch with a few alterations having been adopted, the following officers were elected:—President: Mr. Charles Sims. Vice-President: Mr. F. J. Thorman. Hon. Secs.: Mr. H. Breward Neale and Mr. Frank Huxley. Treasurer: Mr. J. Humphreys. Council: Messrs. F. R. Batchelor, R. King, F. W. Richards, E. Harding, H. Blandy, and S. Birt.

LOWER THAMES VALLEY DRAINAGE.—The Works and Parliamentary Committee of the Lower Thames Valley Main Sewerage Board have submitted to that authority a lengthy report in which, after criticising the action of the Select Committee of the House of Commons in rejecting the scheme of Messrs. Mansergh and Mellis for the drainage of the district, they state that the creation of the board which was to solve the drainage difficulty has been attended with failure. This report was received by the board at the last ordinary meeting, and the plan of Sir Joseph Bazalgette, by which the whole of the sewage from the district of the joint board could be carried to the Crossness outfall, without going through the district of the Metropolitan Board of Works, was referred to the committee for their consideration and report, their report having been presented with full knowledge that such a scheme existed.

HULL GENERAL INFIRMARY.—This building is about to be enlarged by the addition of two wings and the erection of an out-patients' department; and the first stones of these new buildings were laid by His Royal Highness the Duke of Edinburgh and Her Royal and Imperial Highness the Duchess of Edinburgh on the 1st inst. The architects are Messrs. H. Saxon Snell and Son of London, and the builders of the portion now being executed are Messrs. Jackson and Son of Hull. The cost of the whole work will, when completed, amount to £25,000. Drawings of the proposed works of the infirmary building were illustrated in our issue of May 31st last.

PRESENTATIONS.—On October 1st a beautifully illuminated address and handsome carriage clock were presented to Mr. Charu Chandra Bose, on his leaving the Edinburgh City Poorhouse, Craiglockhart, by the officials of the institution. The address expressed the respect and esteem in which he was held, and wished him every success in his future career.—Dr. Woodhouse, on his retirement from the post of one of the honorary medical officers of the General Infirmary at Hertford, after forty-one years' service, was on the 2nd inst. presented with a testimonial which took the form of a handsome silver salver and a purse containing one hundred guineas.

PRIZES AT UNIVERSITY COLLEGE, LIVERPOOL.—The following is a list of the medals, prizes, and scholarships distributed by Lord Derby at University College, Liverpool, on the 4th inst.:—Lyon Jones Scholarships: Mr. R. Sumner, Mr. A. A. Kanthack, Mr. A. J. Burrowes, Mr. T. J. Sweeney. Derby Exhibition: Mr. G. S. Wild. Medicine: Mr. A. W. Collins and Mr. H. L. Pearson (equal), silver medal. Surgery: Mr. J. G. G. Corkhill, silver medal. Pathology: Mr. T. G. Laslett, silver medal. Obstetrics: Mr. E. Buxton, silver medal. Advanced Anatomy and Physiology: Mr. A. A. Kanthack, Torr gold medal; Mr. J. H. Abram, bronze medal. Elementary Anatomy and Physiology and Chemistry: Mr. W. E. Livsey, Bligh gold medal; Mr. G. W. Chaster, bronze medal. Histological Prizes: Mr. A. A. Kanthack, Mr. R. J. M. Buchanan. Medical Jurisprudence and Toxicology: Silver medal, Mr. F. H. Barendt. Materia Medica: Silver medal, Mr. A. A. Kanthack. Botany: Silver medal, Mr. W. E. Livsey. Practical Chemistry: Silver medal, Mr. W. E. Livsey. Students' Debating Society Prizes: 1st prize for essay, Mr. J. H. Lightbody; 2nd, Mr. J. Cunningham; 3rd, Mr. F. H. Barendt. Reports of Medical Cases: Mr. H. L. Pearson. Prize for Specimens: Mr. A. A. Kanthack. Reports of Surgical Cases: Mr. E. Buxton. Debating Prizes: Mr. Collins.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BOSWELL, JOHN IRVINE, L.R.C.P.L., M.R.C.S., has been appointed Medical Officer for the First District of the Faversham Union, vice Atthill, resigned.

ELIOT, ERNEST FREDERIC, L.R.C.P. & L.M.Ed., L.S.A.Lond., has been appointed House-Physician to the Queen's Hospital, Birmingham.

FOOT, ERNEST G., M.R.C.S., L.S.A.Lond., has been appointed Resident Clinical Assistant to the City of London Hospital for Diseases of the Chest, Victoria-park.

GORDON, JOHN JOSEPH, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Infirmary and Workhouse, Hackney Union, vice Garman, resigned.

HARMER, SIDNEY FREDERIC, B.A., has been appointed Demonstrator of Comparative Anatomy in the University of Cambridge.

JELLY, FRED. ADOLPHUS, M.B., C.M.Ed., has been appointed Assistant Medical Officer to the Wynford House Asylum, Exeter, vice Moypan, resigned.

LEWIS, W. BEVAN, L.R.C.P.Lond. &c., has been appointed Medical Superintendent of the West Riding Asylum, Wakefield, vice Dr. Herbert Major, resigned.

Digitized by Google

MCWILLIAM, ALEX., M.B., C.M.Aber., has been appointed Senior Assistant Medical Officer to the Somerset and Bath Asylum, vice Beatty, resigned.

NEWMAN, DAVID, M.D., C.M.Glas., F.F.P.S.Glasg., has been appointed Surgeon to the Dispensary for Diseases of the Throat, Glasgow, vice Dr. Eben. Watson, resigned.

OPENSHAW, T. HORROCKS, M.B., L.R.C.P.Lond., has been appointed Resident Accoucheur to the London Hospital.

PARROTT, THOMAS GODFREY, M.R.C.S., L.R.C.P.Lond., has been appointed Resident Medical Officer and Secretary to the Bournemouth Cottage Hospital.

PEDLEY, RICHARD D., M.R.C.S., L.D.S., has been appointed Dental Surgeon to the Metropolitan Dispensary, Fore-street, Cripplegate.

PINK, THOMAS, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Weldon District of the Oundle Union, vice Stokes, resigned.

PORTER, CHARLES F., M.R.C.S., has been appointed Health Officer for the Port of Port Philip, and Superintendent of the Sanitary Station at Point Nepean, vice Burmer, resigned.

RIDLEY, GEORGE WALTER, M.B.Dur., M.R.C.S., has been appointed Senior House-Surgeon to the Ingham Infirmary, South Shields, vice S. Lowes, M.B., L.R.C.S., resigned.

SMALL, THOMAS, L.R.C.P.Ed., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Tenth District of the Hexham Union, vice Connon.

TOMKINS, HARDING H., M.R.C.S. (late Assistant House-Surgeon to the Children's Infirmary, Liverpool), has been appointed Assistant Medical Officer to the Gloucester County Asylum.

WALLER, CHARLES B., M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to the Westminster Hospital, vice A. Scanlan, resigned.

WELD, JAMES CHARLES, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Health Officer for the Shire of Ararat, Victoria.

Births, Marriages, and Deaths.

BIRTHS.

JONES.—On the 5th inst., at 6, Westbourne-street, W., the wife of T. W. Carmalt Jones, F.R.C.S.Ed., of a son, who survived his birth only a short time.

PICKUP.—On the 30th ult., at Bishop-street, Coventry, the wife of W. J. Pickup, M.B.Lond., of a son.

POPE.—On the 1st inst., at Broomsgrove Villa, Goldhawk-road, Shepherd's-bush, W., the wife of H. Campbell Pope, M.D.Lond., F.R.C.S., of a son.

WEBB.—On the 1st inst., at Kingsbridge, South Devon, the wife of W. H. Webb, M.R.C.S., of a daughter.

WESTLAND.—On the 1st inst., at Belsize-park, N.W., the wife of Albert Westland, M.D., of a daughter.

MARRIAGES.

BROSTER—POOLE.—On the 24th ult., at St. Mary's Church, Longfleet, Arthur Erdwick Broster, M.R.C.S., only son of the late Richard William Broster, M.R.C.S., of Beaminster, to Fanny Augusta, second daughter of Christopher Hill Poole.

EDWARDS—DOUTY.—On the 29th ult., at Netherhampton, by the Rev. Canon Olivier, Rector, assisted by the Rev. M. J. Drinkwater, Rector of St. George's, Antigua, W.I. (brother-in-law of the bridegroom), Charles Reginald Edwards, M.R.C.S.Eng., L.R.C.P., youngest son of W. H. Edwards, Esq., F.R.C.S.Eng., of St. John's, Antigua, W.I., to Lucy Ella, eldest daughter of the late Joel Douty, Esq., of Netherhampton House, near Salisbury.

SHAPLEY—STOCKWOOD.—On the 17th ult., at Newcastle Church, Bridgend, S. Wales, by the Rev. J. P. Hughes, M.A., Vicar of Llantrissant, assisted by the Rev. G. Thomas, B.A., Vicar of Newcastle, Frank Shapley, M.R.C.S., L.S.A.Lond., of Bryngarw, Sidcup, Kent, to Edith Stockwood, daughter of T. Stockwood, Esq., Solicitor, of Caederwen, Bridgend.

STORER—CLARKE.—On the 2nd inst., at Christ Church, Tunbridge Wells, Charles Storer, M.D., of Lowdham Grange, Notts, to Elizabeth, second daughter of the late Lieut. Clarke, R.M.L.I., of Epperstone, Notts.

THOMPSON—BARTER.—On the 2nd inst., at Gowran, co. Kilkenny, by the Rev. J. Stewart Hickey, Rector of Goresbridge, William Thompson, Esq., Surgeon, R.N., of Sandeville, co. Kerry, to Mary Agnes, youngest daughter of the late Dr. Barter, of St. Ann's-hill, co. Cork.

WADE—TODD.—On the 30th ult., at St. Mary's, Finchley, Charles Wade, M.R.C.S., L.S.A.Lond., of Hatfield Broad Oak, Essex, son of Edward Wade, Surgeon, of Cross, Somerset, to Sarah, only daughter of the late Benjamin Todd, Esq., of Finchley.

DEATHS.

BREWER.—On the 29th ult., Thomas Brewer, M.R.C.S., L.S.A.Lond., of New North-road, Huddersfield, aged 44.

DUNCAN.—On the 7th inst., at Great Marlborough-street, W., Peter Charles Duncan, M.D., after long continued suffering.

JOWETT.—On the 3rd inst., at Cedars-road, Beckenham, Joseph Jowett, Surgeon-Major (retired) H.M. Indian Army, second son of the late Rev. Joseph Jowett, M.A., Rector of Silk Willoughby, Lincolnshire, aged 69.

LIVINGSTONE.—On Aug. 9th, at Fitzroy, Melbourne, Andrew Cairncross Livingstone, M.D., L.R.C.S.Ed., late of Edinburgh, aged 72.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

LONDON CABS.

"THE Man About Town," writing in the *County Gentleman*, notices on complaint about the "growler," and says that it "has been anticipated, and the fusty, jingling vehicles described by THE LANCET are being rapidly supplanted by really comfortable carriages." He adds, "Some of the new four-wheelers recently put on the ranks are as neat as need be." Our contemporary will earn the gratitude of a long-suffering public if he will state the precise localities of the ranks on which these much-to-be-desired but rather invisible four-wheelers are to be found. We welcome the announcement that "Forder's have invented a new hackney-coach called a landaulette. This can be driven open or shut." When is it to appear? There could be no better time than "chill" October. The occupation of a cabmaster is just now popular and aristocratic, and possibly profitable. But why do certain noble proprietors of cabs confine their enterprise to the hansom? In all fairness to the "growler," let us hasten to admit that with very slight alterations as to its interior it would be a *perfect* conveyance—for luggage!

T. K.—At St. Thomas's Hospital probationers under the auspices of the Nightingale Fund are allowed £16, besides board, lodging, &c., during their year of training.

R. D. is referred to a general notice at the head of this column.

ENGLISH *v.* FOREIGN OBJECTIVES.

To the Editor of THE LANCET.

SIR,—In your issue of Sept. 27th, in answering a correspondent who signed himself "Microscope," the writer, I suspect, hardly expressed all he intended. He must have meant to say that foreign objectives are superior to English *at the price*. I have elsewhere recorded my admiration of the high-power "immersions" of Zeiss, made on Professor Abbé's formulæ, and which rival the productions of our Powell and Lealand; but foreign low-powers are of inferior quality. Yet on these depends the greater part of practical work. Even in the matter of price the balance is not always against us. During some years I have had occasion to critically examine many glasses by Wray of Highgate (not so generally known as they should be), and I can guarantee their being nearly, or quite, equal to those of our first makers, at less than half the price. A stage-micrometer affords a simple test of excellence of correction. Its ruled lines should appear sharply defined all over the field, and run distinct and without bending to the edge. Still, the beginner must remember that the working image is the joint product of the objective and ocular; and if the latter is defective, as is too often is, spherical aberration will result with the best objective. My experience leads me to prefer Beck's eye-pieces to all others, especially their Kellners.—I am, Sir, yours obediently,

Bristol School of Chemistry, Oct. 4th, 1884. F. W. GRIFFIN, Ph.D.

HAM YARD SOUP KITCHEN AND HOSPICE.

THE committee of the above institution have issued an appeal for funds which deserves a prompt and generous response. Since the institution was founded, in 1846, it has provided over five million meals of soup and bread for the poor of London, and since 1873 it has distributed 558 tons of coals. The relief during 1883 was 153,671 meals, and 1597 nights' lodgings in the Hospice, the Christmas Dinner regaling 5000 persons. It is stated that during epidemics such as cholera, or widespread distress the committee could, if provided with funds, relieve eighteen or twenty thousand persons a week, and distribute disinfectants, &c., to poor families. We are glad to notice that penny dinners to poor school children will be provided during the winter.

Wintonia.—The case is not uncommon; but we cannot depart from our rule.

EARTH AS A DRESSING FOR SPRAINS.

To the Editor of THE LANCET.

SIR,—Being quite familiar with the use and value of clay in treating sprains, and having a very apposite case, I ask the favour of your columns for the following remarks.

Until medical conservatism has seen quackery bring a promising remedy into disrepute (recall electricity, massage, &c.), scientific investigation is often withheld. Ten years ago a distinguished surgeon of Philadelphia, Dr. Addinell Hewson, established the fact of the widespread applicability of clay dressings in medicine and surgery, due, as he believes, to the local anti-inflammatory action of the earth. Wherever hyperæmia or inflammatory action exists, even if more or less deeply seated, clay applications, dry or moist, are thereby indicated. This is the principle involved, and had I the time and space I should be glad to discuss some of the theories suggested to explain its *modus operandi*. While admitting in the case of sprains that the pressure attendant on the clay dressing is to be considered, the criticisms of Drs. Dinin and Robertson on Dr. Shearer's use of the rubber bandage show hasty reading, for the latter distinctly says he applies it "lightly enough to keep the dressing from shifting." In my own practice I simply use a muslin bandage for retentive purposes. The essence of the treatment consists in the complete contact of such a layer of earth in its dry state with the diseased part, so as to thoroughly exclude the air from such parts. The profession have been so slow in following Dr. Hewson's lead in this agency that outsiders who have watched his success are now pushing the remedy with profit to themselves, and a National Pharmacy Association, with extensive warerooms, "combine a number of geological strata ... into a compound of remarkable antiseptic, absorbent, astringent, contractile and healing properties."

My case was that of a young lady who had a terrible fall from a ladder, wrenching her ankle and tarsal articulation severely. The family physician, a prominent homœopath, was summoned. He said nothing could be done till the swelling subsided; and on his next seeing the case, after a few weeks' absence from the city, said it was then too late to do anything. With commendable confidence the lady resigned herself to a life of limping, occasional falls in the street, rest in bed, and in the house painful locomotion and semi-invalidism. After the lapse of about *eight years* the family determined to see a surgeon, requesting his attendance privately. An examination revealed considerable weakness and tenderness of the lateral ligaments, some of the fibres of which had been ruptured; pain was experienced on pressing the articular surfaces together; there was not much swelling or redness, except after exercise. An ankle-brace was ordered to be used in washing, and the foot was dressed with clay, which was adapted to it as a plaster-splint would be. Of course, I ensured perfect rest for the joint. To the satisfaction of the patient and myself anodyne and antiphlogistic effects were obtained. With the aid of the brace, in the course of a month or six weeks she could walk well, being restored to a useful out-door life.

The details of this case are necessarily meagrely given; for I must close with saying that I am neither a "geophagist" nor a "geomaniac," but simply an appreciative son of mother earth.

I am, Sir, yours respectfully,

Baltimore, Sept. 3rd, 1884. EDWARD M. SCHAEFFER, M.D.

A CORRESPONDENT asks: Can the growth of hair upon different parts of the human body be stopped, destroying the hair roots without injuring the skin permanently, otherwise than as to its appearance? If so, how can it be done?

Dr. Victor Geiger.—The holders of degrees or diplomas of recognised foreign universities and colleges have, we believe, no difficulty in obtaining permission to practise in Australia from the Medical Board of the State in which the privilege of practising is desired.

"IS DEAFNESS A BARRIER TO PRACTICE?"

To the Editor of THE LANCET.

SIR,—Allow me to inform "Constant Reader," in answer to his letter in your issue of Aug. 16th, that there is in this city a physician who carries on a large practice although so seriously deaf as to be unable to follow ordinary conversation. The name of this gentleman can be furnished, if necessary. I have also heard of other cases where deafness seemed no bar to *resuming* an established practice. It would, however, doubtless prevent a young man from establishing *ab initio* such a practice. I am, Sir, yours respectfully,

Boston, U.S.A., Sept. 23rd, 1884. E. W. CUSHING, M.D.

THE ALLEGED DEATH FROM THE STEM OF A TOBACCO PIPE.

THE statement made by a lay contemporary that a man had recently died in St. Thomas's Hospital from injury to the brain consequent on the stem of a long pipe which he was smoking perforating the skull through the palate, was entirely disproved by the post-mortem examination. At the adjourned inquest, on Oct. 6th, Dr. Hadden gave evidence to the effect that the man's death was due to natural causes. The left middle cerebral artery was obstructed by a clot, probably detached from an atheromatous aorta, and the left cerebral hemisphere was extensively softened. From various cuts and bruises on the front of the body and face it was evident that the man had fallen forwards. The stem of the pipe had partially detached the soft from the hard palate, but had not penetrated the base of the skull.

Mr. Kerly.—The matter has already been noticed in our columns, but will probably have further attention.

DANGERS OF WEARING HAIR-PINS.

To the Editor of THE LANCET.

SIR,—The following cases appear worthy of record. Mary S——, aged forty-five years, married, robust, and a nullipara, was first seen on July 23rd. She informed me that on July 19th, at 6 A.M., after sitting up in bed for a few minutes, she turned her feet out of bed and slid on to the floor. As she did so she felt something sharp run into her privates, and she called out to her husband. A spot of blood appeared on the night-dress, and she felt two sharp points with her fingers outside; at the same time she missed a pin from her hair. Repeated attempts were made by straining and with fingers to extract it. On examination the points of the pin could not be felt outside nor per vaginam. A silver catheter, passed to three inches, detected a metallic substance on the floor of the bladder, which could be traced between the fingers in the vagina and catheter to the inner end of the urethra. I was unable to make any attempt at removal until the 27th, when fortunately the points of the hair-pin could again be felt at each side of, and about half an inch from, the meatus. After several attempts I seized one arm of the pin with the ordinary tongue forceps, and by pushing the pin back towards the bladder disengaged the point from the mucous membrane of the urethra and brought it down through the meatus, forcing the other point through the wall of the urethra into the vagina. The rest was easily extracted by turning the head of the pin outwards. No inconvenience was felt afterwards.

A somewhat similar, but ludicrous, case is the following, briefly given:—A female, aged fifty years, was visited at 11 P.M., complaining of "agony" in moving and great tenderness of right flank, for a week or more. When the patient stripped, a hair-pin was discovered, with one shank buried in the skin an inch deep.

In neither case do I think imposition or deception at all probable.

I am, Sir, yours truly,

Romsey, Sept., 1884. SPENCER B. SIMPSON.

Chromium.—The condition referred to is familiar enough to every toxicologist. Bichromate of potassium is a powerful irritant poison. Workmen engaged in the manufacture of this article suffer from a bitter, nauseous taste in the mouth, irritation of the mucous membrane of the nose, incessant sneezing, increased secretion of tears, and even severe inflammation of the eyes. Chronic sores often form on the hands, feet, and shoulders. It may in time lead to destruction of the septum of the nose.

POISONOUS EFFECTS OF THE SPANISH BROOM.

To the Editor of THE LANCET.

SIR,—Last week Mrs. S——, aged sixty, a thin woman, got from the nursery garden some tops and seeds of the Spanish broom. She put about half a pint of the cuttings into a pint of water, boiled it down, and drank most of it. In ten minutes a violent perspiration overcame her, the sweat running down her face. She lost her sight, and had the appearance of being drunk. She began to vomit, and the sickness continued for twenty-four hours. In three days she quite recovered. Thinking that the herb might be a strong one, I sent a specimen to Professor Attfield, and he kindly wrote the following:—"The tops and seed vessels you forwarded are those of the Spanish broom (*Spartium junceum*), not the common broom (*Cytisus scoparius*). In small doses it is diuretic, in large doses emetic and purgative."—Yours truly,

Watford, Herts, Oct. 6th, 1884. ALFRED T. BRETT.

Mr. Francis Lance.—A readable book entitled "Medical Fashions in the Nineteenth Century, including a Sketch of Bacteriomania and the Battle of the Bacilli (London: H. K. Lewis, 1884), by Dr. Edward Tibbits, would give the information required.

Dr. C. Y. Biss.—One of the September numbers of the *Lyon Médical*.

"ANILINE DYES."

To the Editor of THE LANCET.

SIR,—*A propos* of the article and letter on this subject which have appeared in your columns, might I direct attention to the fact that some specimens (if not all) of that colouring medium, liq. rosæ dulc., are undoubtedly made with aniline dye. I have a sample at present in my possession. If aniline is really hurtful, it ought not to be used in making such preparations as liq. rosæ dulc.—Yours faithfully,

Oct. 6th, 1884. INTEGRITAS.

ROYAL MEDICAL BENEVOLENT COLLEGE.

THE case of Charles Ambrose Hughes, aged ten years, as a candidate for admission to the above College, has been brought under our notice. He is son of the late S. C. Hughes, M.D., F.R.C.S.I., who held several important appointments in Liverpool, and who was unfortunately killed through a gig accident while visiting his patients. Dr. Hughes was also a life governor of the College, and has left a wife and six children very inadequately provided for.

Young Surgeon.—The production of evidence of the possession of a degree or diploma from any recognised university or college will be accepted by the Medical Board of the colony as a sufficient ground for granting the holder permission to practise. Registration in England is not necessary.

WILLIAM ALLEN AND GUY'S.

To the Editor of THE LANCET.

SIR,—You kindly inserted a note of mine some months ago, specially addressed to Guy's men, asking for information about Allen. That note put me in communication with men of the highest repute in the medical profession, who willingly gave me all the help they could. To you and to them I beg to return my best thanks.

Please add to your kindness by allowing me space for a few words of explanation, for the sake of those interested in Allen. My little book is about to be issued; but the only notice of it I have seen is so misleading that it may well escape the notice of Guy's men. The publishers, Messrs. Hodder and Stoughton, have done what they list with the title, and it is referred to in an influential daily paper as, "The Spitalfields Genius. The Story of William Allen, the Quaker Philanthropist. By J. Tayle, B.A." On the title-page itself there is no reference to Allen being a Quaker philanthropist; for my aim was to write a short and readable sketch, of a Quaker certainly, but in a perfectly unsectarian spirit; of one who was so clever that for twenty-five years he was a most popular lecturer at Guy's, as the letters of Mr. Edward Cock, late consulting-surgeon there, and the only survivor of Allen's classes, sufficiently testify; and of one who was so completely the true gentleman that he was the confidential friend of Her Majesty's father, the late Duke of Kent, the trustee of his estates, and his executor, as well as administrator of his will. He was also the trusted friend of Alexander I., and "Courier to the Duke of Wellington." Well, here be truths which no Guy's man need be ashamed of.

For myself, I object to being turned into a caudal appendage, or a tale that is told, as the Psalmist means it, or even a twice-told tale, whatever may be the spelling, as my name is the Norman-French for a beech tree, and though the bark of the beech was used for writing a story upon, I am not the Story, but the Teller of the Story of Allen, and therefore wish the Tayle to be crossed, as I subscribe myself

Yours indebtedly,

Walthamstow, Oct. 7th, 1884. J. FAYLE.

"A NEW TRACHEOTOMY TUBE."

To the Editor of THE LANCET.

SIR,—I am glad to find that gum elastic has been used for tracheotomy tubes, and that they have given satisfaction. I was perfectly ignorant of the fact when I wrote before on the subject.

Having seen Messrs. C. Wright and Co.'s tubes, I am able to mention some differences in the patterns. My pattern has a shorter vertical portion, a rectangular curve, a somewhat thinner material, a proportionately larger calibre, and a smaller shield, giving a considerable gain in weight. One of my tubes weighs only 24 grs., and has a calibre of a ½-inch diameter.

Messrs. C. Wright and Co. have kindly undertaken to make some tubes after my pattern, and should anyone think them worth a trial they can now be had of them. I am, Sir, yours truly,

Euston-road, Oct. 6th, 1884. A. REA EDWARDS.

"THE FUNCTION OF THE SPLEEN."

To the Editor of THE LANCET.

SIR,—I have just been reading, in your issue of May 17th, a leading article on the above subject, and found therein no reference to the assistance which it possibly gives to the portal circulation. It appears to me to resemble in its use the elastic webbed ball in an ordinary ether spray apparatus, receiving a pulsating current of arterial blood from the heart, distending under the cardiac pressure, and by its elasticity forcing onwards a non-pulsating current of blood into the vena portæ.

Perhaps my note may elicit correspondence on the subject from some of your readers. I am, Sir, yours faithfully,

J. H. NANKIVELL, M.R.C.S.,

Butterworth, S. Africa, Aug. 30th, 1884. District Surgeon, Transkei.

QUININE AND HONEY.

To the Editor of THE LANCET.

SIR,—Honey is the best vehicle I have yet met with for the administration of quinine to children and others to whom the flavour of this drug is very nauseous. If the alkaloid be placed in the centre of a small spoonful of honey, I venture to surmise that the bitter at repugnance to the flavour will be entirely overcome. I have tried glycerine, milk, and other vaunted specifics; but, as our American friends say, they are "not a patch" on honey. I am, Sir, yours truly,

Brighton, Sept. 29th, 1884. DULCE ET UTILE.

YELLOW FEVER.

C. R. (Southampton).—In the *North American Review* for the current quarter the origin of yellow fever is traced to miasmata which are not the natural exhalations of the soil or water, and which cannot arise from soil and water fouled by ordinary sewage. "The filth that breeds it is the filth of the negro race, and furthermore it is the peculiar filth of the 'middle passage.'" The discharges of the sick negro; the dysenteric and other filth of slave-ships fermenting or putrefying in the harbour mud, and tainting the alluvial foundations of houses along the shore and the water conduits—such are the causes of yellow fever. The merit of this induction is given by the reviewer to the French physician, Dr. Audouard, who himself followed up an observation of Dr. James Copland, made in 1817.

Mr. Mayo Robson's paper will appear shortly.

CASE OF POISONING BY CARBOLIC ACID; USE OF THE STOMACH-PUMP; RECOVERY.

To the Editor of THE LANCET.

SIR,—Perhaps the following notes may be deemed of sufficient interest to find a place in your columns.

On the 18th ult., about 10 P.M., J. E——, aged seventy-one, accidentally swallowed a quantity of carbolic acid. In a few minutes he became comatose, and deglutition could not be performed, no doubt in consequence of the paralysed condition of the constrictors of the pharynx and œsophagus. Respiration was extremely laboured, and to all appearances he was dying. Finding he could not swallow, I lost no time in using the stomach-pump, which, in his case was attended with considerable risk, as the tube might unduly press upon the larynx, and so produce asphyxia before the operation could be successfully completed. However, as it was the patient's only chance for life, I carefully proceeded with the operation, keeping the tongue well forward and the head thrown as far back as possible, for obvious reasons. The most important part of the operation being so far successful, I proceeded to inject warm water into the stomach, in order to quickly dilute the acid, and so render it more harmless. On withdrawing the injected water it was found to be strongly impregnated with the acid. I repeated the operation three times, and then injected about a pint of thin gruel with an egg well mixed, to which I added an ounce of brandy, as the heart's action was failing. I withdrew the tube, got the patient quickly placed in bed, and applied warmth to the thorax and extremities. I remained with the patient two hours, to watch the symptoms and keep the throat and mouth clear of the mucus as it accumulated; this was done by means of an extemporised sponge probang. On leaving I gave the nurse instructions to keep him warm and to remove the mucus from the mouth. On visiting the patient in the morning I learned that he had had a very restless night, and that he was unable to swallow until 7 A.M., when he took a little milk. He had no recollection of what had transpired the night before. At the time of the accident the patient was suffering from asthmatic bronchitis, which was now much aggravated; this was, however, soon relieved by a cough linctus, to which was added chlorate of potash. The mouth and throat were dressed with a mixture of chlorate of potash and glycerine. The patient has had a sharp attack of diarrhœa during the last three or four days, which was relieved by the usual chalk mixture. He is sitting up to-day for the first time, this being the thirteenth since the accident, and no doubt in a few days he will be able to leave the house.—I am, Sir, yours faithfully,

Bristol, Oct. 1st, 1884. G. W. GROTE, L.R.C.P., &c.

H. B. S. (Bradford).—The generosity of Dr. Tommasi-Crudeli's vindication of Pacini's claim to the discovery of the "cholerigenous microbe" was appreciated at the Copenhagen Congress only by those of the audience who knew the animosity with which Pacini had attacked Dr. Tommasi-Crudeli himself. The last years of poor Pacini's life were embittered, if not shortened, by the fierce controversies in which he was engaged with his professional colleagues, particularly those of the Tuscan school.

Mr. MacCrombie.—We cannot extend our exchange list.

PHTHISIS.

To the Editor of THE LANCET.

SIR,—Could any of the numerous readers of THE LANCET kindly inform me what is the composition of Congreve's elixir, used in the treatment of consumption? I am, Sir, yours truly,

Oct. 7th, 1884. H. G.

OWING to the length of the report of the proceedings of the Medical Council, we are compelled to hold over several communications already in type.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir Risdon Bennett, London; Dr. Herman, London; Mr. F. W. Lowndes, Liverpool; Mr. J. H. Douty, Worcester; Mr. A. Kerly, London; Dr. T. Oliver, Newcastle-on-Tyne; Dr. Manning, Salisbury; Mr. Buckston Browne, London; Professor Wharton Jones, Ventnor; Mr. Chauncy Puzey, Liverpool; Dr. Norman Kerr, London; Mr. Wheeler, Dublin; Mr. Combie, Coleraine; Mr. Thompson, Hague; Mr. T. A Lecture
ON
DISEASES OF CHILDREN.

Delivered at the Hospital for Sick Children, Great Ormond-street,

BY ROBERT J. LEE, M.D., F.R.C.P. LOND.

INFANTILE AND FAMILY SYPHILIS.

GENTLEMEN,—It is right that I should ask you for some indulgence if I incur the risk of being tedious in the consideration of the subject of Infantile Syphilis. You may be inclined to take the view that there is very little practical use in studying this subject as I propose to do, and that it is enough if we learn to recognise the symptoms when we see them, and can treat a case satisfactorily. Now, so far as the diagnosis of symptoms is concerned, there is usually no great difficulty in recognising them; while the treatment of infantile syphilis may almost be said to be expressed in one word, "mercury." It is not the question of treatment that I propose to consider, nor that of diagnosis; for it would be difficult to give you any information on these points which is not to be obtained from most works on general medicine. You will naturally, then, inquire what object there can be in studying this disease if we exclude all considerations of diagnosis and treatment. Admitting that there may possibly be much to interest those who have the time and disposition to pursue obscure and difficult questions when an extensive field for observation is at their command, still you may feel that such questions are not important enough to occupy the time and attention of the busy practitioner. Let me dispel such an idea from your minds by assuring you that the most extensive field, indeed almost the only one which circumstances permit, for the solution of the most important and difficult questions connected with syphilis, is that which is presented to those engaged in family practice. It is most difficult for the hospital physician or surgeon to do more than diagnose and treat the cases which come under his notice, unless he makes some special provision to overcome obstacles in the way of advancing knowledge, and which in the case of syphilis are, for reasons you can easily conceive, very considerable.

Supposing that we take a dozen instances of infants suffering from the disease brought here as out-patients, what do we learn by comparing them one with another, and noting all the differences between them with the utmost attention to details? If we take cases by hundreds instead of by dozens, all that we learn is to recognise the fact that syphilis in the infant is multiform in symptoms; but why signs and symptoms should differ as they do must still remain a mystery. No increase in the number of cases will furnish the data to answer that question. Nor again will they help us to explain why two or more children in a family may show no signs of infection, while others are born with distinct evidences of it. Such questions as these we ought surely to be able to answer if we set ourselves to the task in a reasonable and scientific spirit, and pursue it with energy, patience, and perseverance. It is sad to look back to the grievous errors which have been promulgated by men of the highest ability, some instances of which I shall have occasion to refer to. We can, however, defer for the present any further remarks of this nature, and turn our attention to the clinical study of the subject.

At the close of the last lecture, a case of infantile syphilis in a child six months old was brought to your notice, of which we were able to obtain a part of the history. In the interval between then and now I have obtained the other part—the most important in many respects—the history given by the father. The mother, you remember, gave a very distinct account of her married life. She told us that she was the second wife, and that her health had been good at all times. At present she is feeling weak from anxiety, and care of the infant; but she has had no symptoms which after proper inquiry could be attributed to syphilitic infection. We then had the account of her children. The first was born dead at term; the second was born dead at the eighth month; the third was born dead at the seventh month; the fourth was born dead at the seventh month; the fifth and sixth were twins, born dead at the seventh month; the seventh is now two years old, and has ailed nothing since birth. The eighth is the infant we have just seen to-day for the second time. The symptoms of syphilis are well marked; the hands and feet are peeling; the parts around the mouth, nose, and ears are slightly ulcerated; the nates are sore; the skin is pale and waxy; and the child has snuffled since it was a fortnight old. It is not at all ill-nourished, and the most marked symptoms are the general cachectic appearance and the waxiness of the skin. You noticed also a considerable amount of swelling and redness around the right elbow-joint; and the right leg was swollen, rather red and shining, a condition which you would pronounce to be erysipelas. There is an abscess in process of formation in the right arm, and I think already there is deep-seated pus. As a rule it is better not to incise in such a case, as there is little or no pain, and the inflammatory action will soon be arrested when the constitutional effects of proper treatment are obtained. I have ordered the mother to give the following medicine: One grain of mercury and chalk every night; one grain of iodide of potassium, twenty minims of syrup of iodide of iron, water to one drachm; to be taken three times a day. The prognosis of the case is very favourable, and some day I shall bring the child under your notice again, and give you an account of the results of treatment. We will now take the history given by the father. He is fifty-one years of age. When between twenty-one and twenty-two he was infected, and was under treatment for two years; so that about thirty years have elapsed since that time. He was twice salivated during the two years immediately following infection, and when he married his first wife eight years had passed. He was then in good health, and has enjoyed good health since, with the exception that he is subject to attacks of asthma. By his first marriage he had four children. The first was born prematurely and dead; the second has grown up and is now a strong and healthy youth, seventeen years of age, who has never shown any symptoms of hereditary syphilis; the third was born prematurely and dead; and the same accident happened to the fourth. The first wife enjoyed good health and died from an acute illness in no way related to syphilis. After remaining a widower for three years he married a second time, nearly twenty years after being first infected. This history is given by a man of rather superior education and intelligence, and from the first there has been a sensible desire on his part to avail himself of the best professional advice within his means. It was his own wish that he should be fully subjected to the influence of mercury, with a result not infrequently observed in similar cases.

I need hardly point out to you what are the questions of chief interest in a case like this. As far as the infant itself is concerned there is nothing to be remarked. Its condition is a common one; and the treatment is simple enough. It is not by any means the most common form of infantile syphilis, but its symptoms were such as at once to make the diagnosis and prognosis certain. It differs in this respect from the most common form of syphilis in the infant: that the child is well nourished and well developed, and the most striking symptoms are the pallor and waxiness of the skin. There is no wasting and no extensive cutaneous ulceration. The cracks round the lips are not deep. The chief troubles are the swellings of the arm and leg. Taking all the symptoms together, you would if you saw them in an adult expect to hear that a considerable interval of time had passed since infection, and that they belonged to what is usually known as the tertiary class of symptoms. As regards the mother, there is nothing whatever to be said. It is of no use discussing the question whether she has been infected or not. There is one thing certain. It is that she may some day show signs of infection, and if she does they will be symptoms of what we call a tertiary character. Note 6 in Fournier's work is a case of this kind. No. 33 in my list is also a case. These are facts which we cannot explain at present, but we shall probably find out the solution by inquiring in each such case into the history of the father. This at least appears to me to be a line of investigation worth attention. It will be convenient, I think, if I make some remarks upon the list of cases I have drawn up in a tabular form of instances of family syphilis, as I shall have occasion to refer to them from time to time. The symbols S_1 and S_2 express as far as could be ascertained the nature or mode of infection to which the mother had

Digitized by Google

been subjected. When she suffered from symptoms of primary infection, and had contracted syphilis directly from her husband, I use the symbol S_1 to distinguish such occurrence from that where the mother was infected through the fœtus, and which is symbolised by S_2. Therefore in looking down the column containing the symbols S_1 and S_2 you can determine at once the form of infection in any particular case or number of cases. In column A the period of time is given which has intervened between the date of the infection of the father and the time of marriage. The object of this is to show to what extent it is probable that time exerts an influence in determining the evolution of specific symptoms in the mother or children, or in both. In column B a question of time is also answered, different from that in column A, and not so important in many respects, but still very necessary to the history of the family. This column gives the period which has elapsed since marriage, and enables us to some extent to compare the conditions observed when the case first came under notice with those reported by the mother or father at earlier periods of their history. I have then arranged in three separate columns the condensed history of father, mother, and offspring. Most of these histories have been taken at considerable length, and most of the details, whether positive or negative, of any importance have been noted. This table might be improved, but only at the risk of increasing its size inconveniently.

Now, in taking notes of the case which we have been considering, you perceive that there are some details especially deserving of attention. The most important fact in regard to the father is not, in my opinion, the long period that elapsed between the time when he was infected and his first and second marriages, nor the fact that he was treated so actively as to have been twice salivated, but it is that he has been the subject of asthma for many years. If this had been omitted the case would have been incomplete, and for the reason that the constitutional tendencies of the individual appear to determine to a great extent the character of the symptoms which generally follow infection, and this, too, quite as much as, if not more than, the simple influence of time. Do not suppose that I have any theory upon this point. I simply state the results of what probably many have observed and are well acquainted with. The importance of noting this fact we shall have occasion to refer to again.

The cases to which most attention should be directed in our present state of knowledge are not such cases as this, nor are they such cases as those mentioned by Fournier, where both mother and infant escaped; nor are they such cases as the 237 of primary infection in the mother mentioned by the same author. The cases of greatest interest now are those where the mother has been infected through the fœtus, and has shown symptoms of such infection; and in taking notes of these cases we must be particularly careful to have a complete history of the father. To refer again to Case 33 in my list. The fact is stated that the father was under treatment at King's College Hospital at the time that the child was brought to us here; and my friend, Mr. Royes Bell, assisted me by his notes of the father's history. I should have no difficulty in proving to you that you will find some such evidence of active symptoms in the father when the mother, through conception, becomes infected. What the relations may prove to be we will at present defer to consider. My object now is merely to explain the necessity of these details if we are to work out the questions of interest and importance connected with this subject.

We will take another case of family syphilis, of which we obtained a partial history last week, and of which I now give you the complete history. Two children were brought by the mother, the elder between four and five years of age, the younger only three months old. The infant presents the common symptoms of infantile syphilis. I mean by the common symptoms those observed in the majority of cases, and which are diagnosed without doubt or difficulty. The skin around the mouth and nose is slightly fissured and ulcerated; the child has snuffled since soon after birth, and the nates are sore, with small superficial ulcers and general redness, tending to a tinge of brown, in the parts around the ulcers. The elder child is between four and five years old; she is delicate and suffering from bronchitis; but, so far as any history of specific symptoms are concerned, we are informed that they have been quite absent. The mother gives the following account of herself. She has always been delicate, and has a tendency to bronchitis. Soon after marriage she had local symptoms of infection, with sore-throat, general weakness, &c. She gradually recovered, and latterly has had good health when not suffering from bronchitis. Of her children, the first was born dead; the second the same; the third was born alive, and died at the age of eight months; the fourth lived to the age of nine months, and suffered like the infant we have just seen; the fifth is alive, but has also suffered; the sixth is the elder of the two children brought here; the last is the infant. In the course of the week I saw the father and obtained from him his history. He is thirty-five years of age, and has been married ten years. Four months before marriage he was infected, and was under treatment, with the result that at the time he married the local symptoms had ceased, and there were no "secondaries." Very soon—that is, a few weeks after marriage—local symptoms returned, and his wife was infected, with the result we have seen. He submitted himself to treatment, and soon recovered, and has been well since. You will probably say at once that this was a case of S_1. It is entered in my list as No. 35. Compare it with No. 36 and with some few other cases. It has appeared to me doubtful whether in married women local sores are always cases of primary infection. At least, they differ generally from the common form which the disease assumes in hospitals specially intended for this malady. In the cases I refer to there is no distinct history of a primary sore. Conception takes place, and soon after—that is, within a few weeks or months—the skin, the throat, and other tissues are affected in a similar way, as far as can be judged, to that which is characteristic of the ordinary symptoms termed "secondary," when following on a primary sore. It seems if we may take the list of the cases I have tabulated, that the most common occurrence in married women is a history of freedom from all symptoms; the next most common is one of what are generally known as tertiary symptoms; and the least common are the cases of active secondaries. I have already said that a case of primary infection is very rare as the direct result of marriage, for the reason given that men do not contract marriage when suffering from local sores. I think you will see that I am arguing in favour of the view that in the condition of the father we must seek for an explanation of the varying symptoms which are presented by the mother and the children.

ON THE PATHOLOGICAL IMPORTANCE OF FLEXIONS OF THE UTERUS.

BY G. ERNEST HERMAN, M.B. LOND.,
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL,
LECTURER ON MIDWIFERY, ETC.

IN communications to THE LANCET[1] on the question as to the "importance of flexions and displacements of the uterus," Dr. Grailly Hewitt has done me the honour of criticising papers of mine on the subject; and I therefore trust I may be allowed space to try to set forth more clearly those parts of my argument in which it appears I have failed to make my meaning plain, and to point out where I cannot help still thinking that Dr. Hewitt's theories are not in accord with clinical fact.

I would ask attention, first, to the difference in title between Dr. Hewitt's papers and my present communication. He writes on "flexions and displacements." I presume that no one will deny that conditions, such as inversion and prolapse, which come under the term "displacements," are morbid changes, and cause symptoms. With regard to bending of the organ, and to its slight inclinations forwards or backwards, there is not the same agreement. I wish here to limit myself to the subject of bending. I think it beyond doubt that when the uterus is not only bent, but fixed in that shape by adhesions, or when a uterus with senile thinning of its wall becomes bent, fluid may accumulate in the uterine cavity. The question at issue is whether *mere bending* of a uterus which is functionally active and free to move prevents the natural painless performance of its functions, or in any other way disturbs health.

Dr. Hewitt says: "It will hardly be necessary to urge that cases do occur in which severe flexions of the uterus

[1] June 7th, 14th, and 21st of the current year.

Digitized by Google

give rise to great suffering, to great pain, and to various inconveniences. Those who deny that this is the case are not in my opinion open in a reasonable way to conviction, and arguments are lost upon them."[2] If this quotation be taken in its most literal sense, and as applying to cases in which neither of the two complications mentioned above are present, I must with regret admit that I am one of those upon whom Dr. Hewitt considers that argument is lost, and can only console myself by recollecting that the same censure applies to a large and increasing number of competent observers. But if I may take Dr. Hewitt's meaning to be this, that there are cases in which flexions of the uterus are *associated* with great sufferings &c. which are relieved by treatment which has for one of its results the removal of the flexion, then I quite agree with him; and the only difference of opinion is as to whether or not the benefit is dependent upon the uterus having been made straight.

In the remarks which follow I shall so often have to speak of the opinions of Dr. Hewitt, that it might seem as if the motive and subject of this paper were purely a personal one; but notwithstanding this disadvantage, frequent reference to Dr. Hewitt is not only unavoidable, but desirable; for he has so thoroughly and clearly elaborated the mechanical system of uterine pathology that, quite independently of his high position in the profession, his writings form its main support, and are the reasons of its wide acceptance; and if it can be shown that even in his writings the theory is insufficiently proved, it must fall to the ground. If Dr. Hewitt can be refuted, there is little else written on that side of the question that need be considered; if, however, a sceptic as to the mechanical system of gynæcology should admit that a flexion of the uterus may be a morbid change, it does not follow that he must accept the mechanical system of gynæcology. There is a great difference between admitting (1) that flexion of the uterus may cause symptoms in a few rare and exceptional cases, and (2) going with Dr. Hewitt in considering flexion of the uterus as the great cause of nearly all the troubles to which women are peculiarly subject. If the former of these two views be established, the latter does not follow from it.

There are four main lines along which the subject has been investigated, and which Dr. Hewitt considers in his papers, though not with equal fulness. These are—(1) statistical evidence; (2) post-mortem evidence; (3) the interpretation of signs and symptoms; and (4) the effect of treatment. To each of these I would ask attention.

1. *Statistical Evidence.*—The only statistics collected for the purpose of dealing with this question, and the only ones with which Dr. Hewitt deals, are my own and those of Vedeler. I place my own first, because they were slightly the first in order of time; but the two papers were published nearly simultaneously. Vedeler, in his first paper, makes no reference to mine, so that it is probable he had not seen it, and his observations are so numerous that he must have, at least, begun to make them before my paper was published; so that Vedeler's observations and mine were quite independently made; and they confirm one another. There are other statistics to which I have referred in my papers published in the Obstetrical Transactions,[3] which, in so far as they touch the points in question, give results similar to those obtained by Vedeler and by myself. These statistics agree in showing this broad fact—viz, that flexion of the uterus is extremely common in healthy women. This is the result attained by the only investigators who have sought to find out how often flexion occurs in the healthy. Those writers who adopt to its full extent the mechanical theory of the diseases of women take for granted, without special investigation, that the uterus in health is straight, or almost straight, and that any considerable bending is a morbid distortion. Vedeler's researches and mine concur in showing that this view, which is a fundamental principle of the mechanical pathology of the diseases of women, is erroneous; and these researches have not been rebutted by observations of the same kind. This fact is clearly established (so far as the evidence of two persons can settle anything) by the only persons who have sought to find out how often flexion of the uterus occurs in healthy women.

Dr. Hewitt, although he has no observations to oppose these, and there are none which show any different result, points out sources of error which he thinks invalidate the conclusions, and these I proceed to examine. First, he wishes a precise definition of "health" and of "complaints," and argues that the symptoms which flexions cause have not received attention or adequate recognition by previous writers; that they are often reflex; that very likely they were absent in Vedeler's patients because these belonged to the lower class; that the flexion may have only just developed, and have not had time to produce distress. These objections, it appears to me, have some weight, but not enough to prove Dr. Hewitt's theorem. If all that Vedeler's figures and mine showed was that symptoms were a little less frequent with flexions than Dr. Hewitt believed, or if Dr. Hewitt only asserted that flexion was occasionally and rarely a cause of mischief, then these sources of possible error might account for the difference in result. But when observation on the one side shows that flexion of the uterus is present in the majority of women, and almost exactly as often in those who are in perfect health as in those who suffer from uterine symptoms, while on the other side Dr. Hewitt asserts that flexion of the uterus is "the most common and most troublesome of the maladies to which the uterus is subject," and by far the most common cause of every disturbance of uterine function, it appears to me that the divergence is wider than can be accounted for by any such explanations. Dysmenorrhœa and menorrhagia, for instance, which, according to Dr. Hewitt, are almost inevitable results of long-continued flexions, are not occult, reflex symptoms, likely to be overlooked by anyone not an experienced specialist, and they are met with in the lower as well as in the upper classes. If flexion produces mischief of this kind with the frequency that Dr. Hewitt believes, it is impossible that out of several hundred cases of flexion the numbers with and without symptoms should have been almost exactly even. My own investigation was limited to the one symptom of dysmenorrhœa, of which, according to Dr. Hewitt, uterine flexion is not merely an occasional cause, but the great cause; and as to the presence and severity of this symptom special inquiry was made. Dr. Hewitt suggests that some of the patients may have been suffering from chronic ovaritis; but assuming this to be so, such cases would be distributed equally among the bent and the straight uteri, and so would not affect the result (unless it be maintained that flexion prevents ovaritis). Dr. Hewitt brings some other objections, the bearing of which I do not perceive. He speaks of the hardness or softness of the uterus. This he says introduces fallacies in examination, and he specifies the use of the sound. This instrument was not employed in any of the cases used for my investigation, from the fear of carrying diseased secretions from the vulva into the uterus; so no fallacy can have arisen in that way. He also speaks of the "double examination." I presume that this means that when the uterus was soft anteflexion was artificially produced. I do not think this was so, for the bimanual examination was always preceded by the vaginal. Some uteri may have been soft and others hard, but I do not see how this can affect the figures. Then Dr. Hewitt says that in some the flexion would be increased, in others diminished, during menstruation. I do not see how this can affect the result either, unless it be asserted that during menstruation straight uteri become bent, and bent ones straight. If this be the meaning intended, I would answer that there is no evidence that any such changes occur; and it may be remarked by the way that it is a statement which must bewilder those who think it their duty in the treatment of dysmenorrhœa to to try to cure flexions; for where is the need of straightening a canal which spontaneously gets straight during the time at which a bend would be hurtful? And how is a bend to be treated which is never present at the time eligible for treatment? It therefore appears to me that Dr. Hewitt's objections do not invalidate these statistics, and that this broad fact stands out clearly and decidedly—viz, that more or less flexion of the uterus is present in the majority of healthy women.

The next point upon which the statistics afford information is the relative frequency of flexion of the uterus in dysmenorrhœal and non-dysmenorrhœal patients. Dr. Hewitt makes some most cogent and valuable criticisms, and throws additional light on the question by his rearrangement of the figures. The statistics under consideration are contained in Vedeler's second paper. Dr. Hewitt, in the earlier part of his remarks on this paper, is not so happy as in his later ones, for he treats the figures in such a manner as to deprive them of all bearing on the question of flexions. It is this question which Vedeler discusses, and to which I here con-

[2] THE LANCET, June 21st, 1884, p. 1110. [3] Vol. xxii. and xxiv.

fine myself. Dr. Hewitt mixes up versions and flexions together. Whatever effects version of the uterus may produce, if we want to understand those of flexion we must keep cases in which the uterus is bent distinct from those in which it is straight.

Although it may be wearisome to the reader, I must proceed to substantiate this statement. Vedeler[1] divides anteflexions into three classes:—(1) the first degree, in which the ante-curvature forms an angle greater than a right angle; (2) the second degree, in which the flexion is about at a right angle; and (3) the third degree, in which the uterus is so much bent that the body and neck are nearly parallel. Dr. Hewitt quotes him to the effect that there were 59 virgins who had no dysmenorrhœa, and in 24 of whom the uterus was in a state of marked flexion or displacement. Vedeler's statement is that of the 59 virgins the first degree of anteflexion was present in 30, the second degree in 9, the third degree in 6, and retroflexion of the first degree in 2—that is, flexion of some degree in 47 and pronounced flexion in 15. Dr. Hewitt gets his figure of 24 by taking this 15 and adding to them the 2 cases of slight retroflexion, 4 cases of anteversion, and 3 of retroversion. He similarly confuses, as I think, Vedeler's statistics of the unmarried, for he quotes him as having found in 101 unmarried women 51 instances of "marked flexion or displacement." Vedeler, out of this 101 unmarried women menstruating without pain, found some flexion in 65 and pronounced flexion in 28. Dr. Hewitt takes 28, adds to them 14 anteversions and 9 retroversions, and so gets the figure 51. He next quotes Vedeler as having found in 92 married women 13 cases of marked flexion or displacement. In this instance, for some reason which he does not explain, he has not included the versions. Vedeler, out of the 92, found more or less flexion in 47 and marked flexion in 13. Taking the three classes together, says Dr. Hewitt, the cases of marked flexion or displacement amounted to 22 per cent. (non-dysmenorrhœal). The percentage, in Dr. Hewitt's mode of tabulation, I make to be 34·9. The 22 per cent. is the proportion of flexion of the second and third degrees, according to Vedeler, the total percentage of flexions of every degree being 56. Dr. Vedeler's next table consists of 100 cases of severe dysmenorrhœa, and Dr. Hewitt deals with this in the same way. He says, "Of 13 virgins, 8 had marked flexion or version." Vedeler's statement is, that of the 13, 5 had anteflexion of the first degree, 1 retroflexion of the first degree, 3 anteflexion of the second degree, 2 anteflexion of the third degree, and 2 retroversion—that is, 11 had more or less flexion and 5 marked flexion. Dr. Hewitt makes 8 by putting together the 5 marked anteflexions, the slight retroflexion, and the 2 retroversions. "Of 44 unmarried women," says Dr. Hewitt, "19 presented the same condition." Vedeler gives 47 unmarried women, 44 of whom were nulliparæ. The distinction between unmarried women and nulliparæ is important, because Dr. Hewitt, as will presently be seen, does not always bear it in mind, and consequently incorrectly uses the figures. Of the 44 nulliparæ, the 19 displacements computed by Dr. Hewitt are made up of 6 anteflexions of the second degree, 5 of the third degree, 2 retroflexions of the first degree, 2 anteversions, and 4 retroversions. There appear in Vedeler's table, beside these 22 anteflexions of the first degree—that is, 35 flexions of all kinds—11 marked flexions. The 100 dysmenorrhœal cases are completed by 43 women who had had children or were married (not 43 married women, as Dr. Hewitt gives it, but 40). In these 43 Dr. Hewitt finds 22 "similarly affected." These 22 are composed of 4 anteflexions of the second degree, 7 anteflexions of the third degree, 2 retroflexions of the first degree, 4 anteversions, and 5 retroversions. Besides these, Vedeler states there were 16 anteflexions of the first degree. In all there were 29 cases of some flexion, 11 of marked flexion. Thus, says Dr. Hewitt, 49 out of the 100 had marked flexion or version. The figures, properly arranged so as to show the effect of flexion, are as follows: "out of the 100 there were 75 cases of flexion, of which 48 (44 anteflexions and 4 retroflexions) were slight, and 27 marked. This minute and tedious examination of the figures may seem of small importance; but if conclusions are to be drawn from these figures, it is necessary that they should be correctly given.

I now leave these details and pass to the more important summary of the figures. Vedeler's results are:—That out of 100 cases of severe dysmenorrhœa, in 71 there was more or less flexion and in 27 marked flexion; of 252 cases in which there was no dysmenorrhœa, in 56 per cent. there was more or less flexion and in 22 per cent. marked flexion. This, to quote Vedeler's own language, "appears to speak in favour of the great influence of flexion, and to strengthen the prevalent teaching that anteflexion is especially connected with dysmenorrhœa or one of its causes." But he goes on to say that we cannot accept these figures without allowing for the effect of pregnancy and parturition, the changes due to which often remove anteflexion. Of the 100 patients suffering from dysmenorrhœa, only 18 had had children; while of the 252 non-dysmenorrhœal cases, 95 had had children, or 37·7 per cent. Vedeler says, and Dr. Hewitt agrees with him, that nulliparous patients suffering from dysmenorrhœa must be compared with nulliparæ not so suffering. Dr. Hewitt accordingly makes such a comparison in what he believes to be an accurate summary of the tables in Vedeler's second paper. He says that in 160 nulliparæ, non-dysmenorrhœal, there were 47 decided flexions, and including all flexions, 103, or 64 per cent. Here, however, he is slightly in error, because, as I remarked before, he has not noticed the distinction between the unmarried and the nulliparous. Vedeler's table includes 59 virgins and 101 unmarried women; and it is the statistics of these that Dr. Hewitt has quoted. But of these unmarried, 13 had had children; while among the 92 married there were 10 who had not had children. When the necessary correction is made, by eliminating the 13 who had been mothers from the list of the unmarried, and adding the ten childless wives to those that remain, we get these figures: 157 nulliparæ with 108 flexions of all kinds, or 68·7 per cent.; and 44 flexions of marked degree, or 28 per cent.

There is yet another correction which has to be made before the figures can be properly used as a test of the effect of bending of the uterus. In drawing the distinction between slight flexions and decided flexions, Dr. Hewitt puts in the latter class anteflexions of Vedeler's second and third degrees, and retroflexions of any degree. I am aware that Dr. Hewitt does not consider a slight degree of anteflexion as inconsistent with health. But the question now under consideration is the effect of bending of the uterus; and from this point of view we should put as much separate slight from decided retroflexions, as we should slight from decided anteflexions. In Dr. Hewitt's 47 decided flexions there are four retroflexions of the first degree, which being deducted leaves 43 only. None of these four had been mothers; while among the 10 childless wives there were 2 with retroflexion of the first degree. This makes 6 to be deducted from the 44 above spoken of, leaving 38, or 24·2 per cent.

Dr. Hewitt objects to Vedeler's comparison, because this puts the dysmenorrhœa cases side by side with the table of healthy nulliparæ—that is, patients who said they were well, but who were not specially questioned as to menstrual pain, in his first paper, instead of with the table of nulliparæ known not to suffer from dysmenorrhœa contained in the second paper. This, I think, a very fair objection, and a very important criticism. In my judgment he here points out an error in Vedeler's mode of reasoning, although he does not show a flaw sufficient to make the figures tell in favour of his own position. I would even go so far as to say that Vedeler's figures, as arranged by Dr. Hewitt, form stronger presumptive evidence in favour of the production of dysmenorrhœa by flexion of the uterus than anything that has yet been brought forward. The figures, arranged in the manner in which Dr. Hewitt has pointed out that they ought to be arranged, and computed according to his view, stand thus:—

	Decided flexions.	All cases of flexions.
	Per cent.	Per cent.
157 Nulliparæ (non-dysmenorrhœal) ..	44, or 28	108, or 68·7
82 Nulliparæ (dysmenorrhœal)	20, or 35	63, or 76·8

But to make the figures show the effect of bending of the uterus, we must remove from the total of decided flexions the slight retroflexions as well as the slight anteflexions, and then the figures stand thus:—

	Decided flexions.	All cases of flexions.
	Per cent.	Per cent.
157 Nulliparæ (non-dysmenorrhœal) ..	38, or 24·2	108, or 68·7
82 Nulliparæ (dysmenorrhœal)	25, or 30·5	63, or 76·8

My own figures relate to the same class of patients as Vedeler's, but are smaller in number. I think the best use

[1] Archiv. für Gynäkologie, Band xxi., S. 228.

Digitized by Google

I can make of them here is to add them to Vedeler's and give the result of the two sets of figures combined. They are as follows:—

	Decided flexions.	All cases of flexions.
	Per cent.	Per cent.
238 Nulliparæ (non-dysmenorrhœal) ..	76, or 32 ..	154, or 65·8
115 Nulliparæ (dysmenorrhœal)	41, or 35·6	84, or 73

The figures thus show a slightly greater frequency of flexions of the uterus among patients the subject of dysmenorrhœa. If this be admitted as an established fact, it still does not show that the flexion stands to the dysmenorrhœa in the relation of cause to effect. It may be that both flexion and dysmenorrhœa are the results of causal conditions common to both. For instance, statistics collected by Whitehead[5] and others by West,[6] show that women in whom menstruation does not commence until later than usual—that is, those in whom the development of the uterus is imperfect—are more prone to derangements of health connected with its functions than other women; and a paper by Dr. John Williams was read before the Obstetrical Society of London in 1882 in which it was maintained that in cases of primary dysmenorrhœa (the kind chiefly met with in nulliparæ) the uterus is imperfectly developed. Now, according to Dr. Hewitt (from whom I do not here differ) the uterus in early life is more anteflexed than subsequently, and this anteflexion disappears as the organ enters upon functional activity. Assuming these views to be correct, we have here an explanation of the preponderance of flexion among the dysmenorrhœal—viz., that among such patients an undue proportion of imperfectly developed uteri is present. But to pursue this subject would be to discuss that of dysmenorrhœa, and I wish here to keep to that of flexion. If the inference which I presume Dr. Hewitt would draw from these figures be correct—viz., that the preponderance of flexions among the dysmenorrhœal indicates that the flexion is the cause of the dysmenorrhœa,—I would point out, first, that it does not follow that the dysmenorrhœa is produced by blocking the canal; next, that the proportion of flexions met with in the non-dysmenorrhœal is very large, and the excess of that condition in the dysmenorrhœal very slight. If it be assumed even that in every case of flexion with dysmenorrhœa the flexion was the cause of the dysmenorrhœa, it still results that 47·3 per cent. of decided flexions, and 47·4 per cent. of all flexions, are quite innocent of any connexion with menstrual pain. Taking the more reasonable estimate, that the number of cases in which the flexion stood in a causal relation to the dysmenorrhœa is represented by the excess of flexed uteri among the dysmenorrhœal cases, we find this consists of 7·2 per cent. of all flexions, 9·6 per cent. of marked flexions. If these figures indicate that flexion is a cause of dysmenorrhœa, they also indicate that it is one of the least frequent, and, therefore, least important causes. It will be noticed also that the slight disproportion is larger when flexions of all grades are taken into account than when marked flexions only are regarded, which goes to show that dysmenorrhœa associated with flexion does not increase in frequency proportionately to the sharpness of the bend, as it should do were it mechanically caused by the bending.

Such a large percentage of flexions among the dysmenorrhœal, and such a trifling difference in this respect between them and the dysmenorrhœal, seem to me altogether inconsistent with the view that Dr. Hewitt takes of the importance of the flexed condition—viz., that it is "the most common and most troublesome of the maladies to which the uterus is liable," and the cause of dysmenorrhœa in the majority of cases.

(To be concluded.)

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—At the first meeting of this Society, held in the Faculty Hall on the 3rd inst., the following gentlemen were elected office-bearers for the present session:—President: Dr. G. H. B. Macleod. Vice-Presidents: Drs. Hugh Thomson and David Taylor (Paisley). Council: Drs. D. Maclean, J. C. Woodburn, William Whitelaw (Kirkintilloch), W. A. Wilson (Greenock), R. Cowan, J. A. Lothian, William Patrick, and M. Thomas. Secretaries: Drs. W. L. Reid and J. W. Anderson. Treasurer: Dr. Hugh Thomson.

A SIMPLE METHOD OF WASHING OUT THE BLADDER.

BY G. BUCKSTON BROWNE, M.R.C.S. ENG.

IN the treatment of various diseases of the urinary organs it is often necessary to teach a patient to wash out the bladder. As a rule he is elderly and not very skilful, and consequently the apparatus put into his hands should be of a simple kind. In all the instruments hitherto designed there are taps to turn, and the injecting nozzle has to be constantly connected with the catheter and disconnected; hence they all lack the element of extreme simplicity; moreover, none of these movements can be made without shifting the catheter more or less, and this is very undesirable in a tender and perhaps inflamed bladder.

In February of this year Dr. Wm. Job Collins published in THE LANCET a description of a two-way tap, furnished with two stopcocks, and intended to be fixed to an ordinary Higginson's enema syringe. This excellent contrivance at once suggested to my mind the following arrangement, in which all stopcocks are done away with, and by which washing out the bladder is made as uncomplicated as possible. The accompanying figure will for the most part

explain itself. A B C D is simply a bifurcated brass tube without valve or stopcock. The end, D, is fixed to a Higginson's syringe. At A and B are discs to support (in addition) the left thumb and second finger, the left forefinger being free to alternately close and leave open the orifice of the efferent tube at C. The jug, E, contains any bladder wash prescribed by the surgeon, and the enema apparatus is filled with it in the usual way, so that all air is expelled. The catheter is then passed, and when urine ceases to flow the nozzle is introduced into the end of the catheter. The left forefinger is firmly applied to the orifice at C, and two ounces of injection are gently introduced into the bladder

Digitized by Google

by squeezing the ball in the right hand. The left forefinger is then raised and the fluid issues from the bladder, while the right hand relaxes its pressure and allows the bulb to draw up a fresh supply of fluid. This process can be repeated as often as is desired, without trouble to the patient or disturbance of the catheter. In practice, I have found this simple apparatus prove of great service to patients suffering from atony of the bladder or prostatic disease, when washing out the bladder has been indicated. The brass nozzle is made by Messrs. Weiss and Son.

Wimpole-street, W.

A NOTE ON PREPUCE GRAFTING.

By CHAUNCY PUZEY,
SURGEON, NORTHERN HOSPITAL, LIVERPOOL.

THE article by Mr. Clement Lucas, which appeared under the head of "Prepuce Grafting," in THE LANCET of Oct. 4th, reminds me of a case bearing upon this subject which was under my care about a year and a half ago in the Northern Hospital, Liverpool.

A sailor, about thirty-five years of age, sustained a severe crush of the soft parts of his left foot, owing to a spar falling upon it and rolling about on it during a heavy gale at sea. The injury was aggravated by want of attention and exposure to cold and wet for several days, so that when the ship arrived at Liverpool and the man was brought to hospital, the integuments of the foot, from the toes to the flexure of the ankle anteriorly, and as far as the os calcis on the plantar aspect, were sloughing, and soon came away, leaving a large granulating surface all round the foot (with the exception of that part occupied by the fifth metatarsal bone, which part had escaped injury, and was covered with sound skin) and from the bases of the toes to the lines before-mentioned, the sheaths of several of the extensor tendons being exposed on the dorsal surface of the foot, and a considerable portion of the plantar fascia having sloughed away. This looked a case which would take months in healing, and in which even then a tender foot, crippled by tight cicatrices, must result—a typical case for extensive skin grafting. Therefore, as soon as the wound was in a clean and favourable condition, I obtained the patient's sanction to the removal of as much skin as might be required from a part where there was plenty—namely, his scrotum. This having been cleansed by the continuous application of carbolised fomentations for a couple of days, I removed two folds of this skin, each about the size of a crown-piece, but oval rather than circular, having previously passed two or three long and thick catgut threads through the folds, near the line of section. One of these pieces was then spread out on the dorsal, the other on the plantar surface of the foot, the catgut being used for tying down the transplants and preventing their tendency to roll up. Carbolised dressings were used, but when they were removed after forty-eight hours, the transplants looked dark and sodden, their cuticle was separating, and the wound had a bad odour. Frequent cleansing, and gauze and oakum dressings, soon improved affairs, but the transplants looked as if they were softening down and would soon disappear. A boy having been found who required circumcision, his prepuce was divided into half a dozen pieces, and these were laid upon the wound in various places between the scrotal transplants and the healing edges of the sore. These preputial grafts adhered at once, and the condition of the sore rapidly improved; moreover, in the site of the scrotal transplants, which we thought had failed, new skin rapidly appeared, and in the course of a few weeks the whole of the large granulating surface was completely healed, partly by cicatrisation, but to a great extent covered with healthy skin. Weeks instead of [illegible] for the restoration of a perfectly [illegible] and foot.

[illegible] much better material than [illegible] is difficult to imagine [illegible] of a healthy infant—this [illegible] and thus readily adapted to any [illegible] these days of [illegible] [illegible] general hospitals in [illegible] [illegible] patients, discomfit [illegible] supply, though the [illegible] objections on [illegible] purely sentimental; still this objection has no doubt hitherto stood in the way of utilising a material which, in these days of conservative surgery, is too valuable to be wasted.

Liverpool.

CASE OF SPORADIC TYPHUS, WITH HIGH TEMPERATURE, COMPLICATED WITH ULCERATIVE ENDOCARDITIS; POST-MORTEM EXAMINATION.

By AUGUSTUS H. COOK, L.R.C.P, M.R.C.S.,
MEDICAL OFFICER TO THE HAMPSTEAD INFIRMARY.

FANNY W——, aged twenty-three, married, was admitted to the infirmary in the evening of April 26th of the present year, with the following history, ascertained from her husband. The illness commenced on Tuesday, April 22nd, four days before admission. She was perfectly well in the morning, and did her washing as usual; but before dinner she felt so weak that she had to lie down, and complained of feeling very ill. She vomited and retched from the time of the seizure till the end of the week, and complained of severe headache. Her skin was burning hot, and her feet very cold, "like ice." She refused all solid food. She was cheerful and perfectly sensible. During the whole time the pain in the head was very severe ("awful"). She bore the journey to the infirmary well, expressing a wish to get there. When she was an infant all her family had typhus, at Wootten-under-Edge, Gloucestershire, her case being the worst; she had typhoid fever when older, and rheumatic fever severely at the age of twelve, but she did not know of any heart disease being left in consequence; she was one of twelve children, and healthy. The patient was confined four months ago, natural labour; but has never been so strong since. Her father and mother are still living, aged forty-three and fifty respectively; both are strong and healthy. Two brothers died young ("of vaccination"); two brothers are still living, both healthy; three sisters, all healthy; her baby, aged four months, is healthy; no other illnesses known. She was in the habit of leaving the unwashed napkins under the bed in which she and her husband slept, for days together, and the smell was very bad at times, especially just before her illness, when the soiled napkins had lain beneath the bed for three or four days—so much so that her husband complained about it. On admission she stated that she had been ill for nearly a week, and that the doctor thought she was a bad cold. She did not appear very ill, but the temperature was 103·8° F.—27th: At about 6 A.M. the patient became unconscious, and when first seen by Dr. Paddle and myself at 11 A.M. she was in the same state. On stimulation she opened her eyes, but showed no other sign of consciousness. Temperature 103·6°; pulse 120; pupils unequal, the left dilated. No signs of any rash, with the exception of a few light-brown stains about the flanks and abdomen. The tongue was a little tenacious and frothy mucus streaked with blood, but careful examination failed to detect any sign of pneumonia. A soft blowing murmur replaced the first sound at the apex. The urine was drawn off by catheter.—28th: Temperature fallen to 102·8°; pulse 120. Patient very delirious, but able to converse with her husband a little. Room, which had been confined throughout, opened by [illegible]. Beef-tea, milk, eggs, &c., taken freely. Incontinence of urine.—29th: Morning temperature, 104°; pulse [illegible]. Prostration extreme; patient still delirious. Temperature at 6 P.M., 106°; 108° at 9 P.M. The patient died at 11.

Autopsy, forty hours after death (at which I was assisted by Dr. Paddle).—The body was fairly well nourished; no eruption, but marked lividity along the back; rigor mortis still present. A dark clot was found on the surface of the brain, over the posterior half of the left hemisphere, about four inches long by one and a half inches wide; it was quite superficial; the vein under the clot was empty. All the superficial veins were gorged with blood, and the membranes were congested but free from opacity, flakes of lymph, or other signs of inflammation; there was little or no effusion into the subarachnoid space or ventricles. The [illegible] section, was found to be greatly congested. There were [illegible] hæmorrhages into the following parts, namely, [illegible] anterior and outer part of the right frontal lobe, about the size of a pea (the centre of this clot was [illegible] colour); (2) in the posterior part of the [illegible]

Digitized by Google

outside the optic thalamus, of rather larger size than the above; (3) in the left hemisphere on the outer side of the posterior cornu, beneath the seat of the superficial hæmorrhage, which probably came from this source. In the cerebellum a considerable hæmorrhage was found in the right lobe, where its substance was broken down; and a slight clot in the opposite lobe. In the pons and medulla the veins were gorged, but there were no hæmorrhages. The pericardium contained three or four ounces of slightly turbid serum, containing flakes of lymph. On the parietal surface there were numerous well-marked petechiæ, about the size of a pin's head; there were none on the visceral surface. The heart contained dark-coloured fluid blood on both sides, also soft, light-coloured clots extending into the pulmonary artery and the aorta. The mitral valve was thickened and beaded, and the posterior flap presented a fresh ulcer, thickened and raised, about the size of a pea; and about an inch from this a second smaller ulcer at the free margin of the valve. Loose vegetations were on the surface of both ulcers, which came away easily on washing. All the remaining valves were healthy. There was no hypertrophy or dilatation, but the heart substance was soft and friable. The lungs were greatly congested throughout, especially the bases and posterior part, presenting the appearance of the first stage of pneumonia. Over the apices and anterior free borders there were numerous small round petechiæ. The bronchial tubes were congested and full of dark frothy mucus. There were no cavities. The right lung weighed 24 oz., and the left 20 oz. The abdomen was retracted. On opening it the peritoneum was found healthy, and its cavity free from fluid or flakes of lymph. The liver weighed 46 oz.; it was pale, but superficial veins and capillaries were mapped out over certain areas from congestion, giving it a mottled appearance; there were no hæmorrhages into it, but it was very friable. The spleen was much increased in length, weighed 14½ oz., was black, and of semi-fluid consistence. The right kidney weighed 7 oz., pyramids deeply congested, cortex normal, the whole soft and friable; the left weighed 7½ oz., pyramids congested; three or four dark nodules were seen on its surface, which on section proved to be recent wedge-shaped infarcts, dark at the circumference, yellowish in the centre; also very friable. The uterus was of normal size and consistence, the lining membrane was congested and softened. The intestines, except the lower part of the colon and rectum, were found congested. There were three or four large dark-coloured extravasations beneath the peritoneal coat, one in the jejunum, two in the ileum, and one or more in the ascending and transverse colon; there were also one or two small infarcts on the surface of the colon. The mucous membrane was carefully examined throughout, and no signs of enlargement or ulceration of Peyer's patches, or solitary glands, could be found.

Remarks.—This case is of interest from the difficulty of the diagnosis during life, owing to the absence of the characteristic rash and the rapidly fatal result on the eighth day. The diagnosis was based upon the early prostration, delirium, and coma; and upon the course of the temperature, with the absence of diarrhœa, tympanites, signs of pneumonia, or other sufficient cause to account for the fever; and it was verified by the post-mortem examination, which presented all the appearances generally found in a case of typhus.

Denning-road, Hampstead, N.W.

ON THE TREATMENT OF A CASE OF

ACUTE CATARRHAL INFLAMMATION OF THE MIDDLE EAR BY REMOVAL OF ACCUMULATED SECRETIONS FROM THE TYMPANUM THROUGH THE EUSTACHIAN TUBE.

BY SAMUEL SEXTON, M.D.,

AURAL SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY.

THE possibility of relieving the tension and consequent pain and discomfort due to the accumulation of secretions in the middle ear by means of suction applied to the outlet of the Eustachian tube in the pharynx has often occurred to other otologists as it has to myself, but the operation, I believe, has been hitherto regarded as impracticable. The opportunity having been recently offered me to successfully demonstrate its practicability, and, it may be added, its simplicity, the case is reported with the hope that others may be induced to test a plan of treatment which promises more speedy relief, in certain cases at least, than is attainable by other methods. A single case, certainly, does not ordinarily afford sufficient experience from which conclusive deductions may be obtained in recommending a new departure in practice, but in the instance to be cited below the observations were confirmed by the patient himself, a person in every way capable of judging of the symptoms and sensations experienced. The case was that of my friend Prof. J. D. Bryant. He had become much run down by overwork, and, contracting a severe head cold, was taken with consecutive otitis media catarrhalis acuta on Jan. 29th, 1884. The two ears were affected in the beginning, and there was much tinnitus and autophonia, both of which symptoms increased on the 30th to such a degree that his lecture on that day was delivered with great discomfort. There was vertigo with nausea, occasional unsteadiness of gait, and very considerable impairment of hearing. The phenomenon of staggering was notable, the patient experiencing concussion of the brain and confusion of ideas from the sound of his own voice, as he himself stated, "the sound of my own voice was so confusing that coördination and locomotion were difficult." On the 31st inst. the trouble began to concentrate, as it seemed in the right ear, which was now the seat of so much pain that he came to consult me about it.

Appearance of the Ears.—The left membrana tympani was slightly hyperæmic about the short process of the malleus, but was otherwise free from inflammation. The right membrane had the general appearance of being intensely inflamed, but on close inspection the inflammation was found to be confined to the membrana flaccida for the most part; indeed, the posterior part of this structure was greatly distended, and was bulging out as though it would burst. The contiguous dermic layer lining the superior posterior wall of the canal was, for the distance of some lines, elevated and very red. The intumescence also extended somewhat downwards along the posterior margin of the membrana tympani, being sharply limited anteriorly at the malleus handle. The swollen membrana flaccida overhung the comparatively unaffected inferior segment of the membrana tympani, thus giving the appearance of much more general distension than actually existed. This case, it will thus be seen, belonged to a rather uncommon form of middle ear inflammation, since the region of the organ affected was the upper chamber of the tympanum, which lies back of the membrana flaccida and immediately beneath the tegmen tympani. The overhanging intumescence above alluded to, and entirely concealing the rest of the membrane in certain cases, is most puzzling to the observer when the true nature of the disease is not recognised, and it is in such cases that disappointment is liable to be experienced in consequence of the escape of air only when the membrana tympani is punctured, the pent-up secretions being confined to the upper chamber. On being asked by the discerning surgeon who was seeking relief if the confined secretions might not be drawn out through the Eustachian tube, it occurred to me that the operation could be successfully performed by means of the flexible Eustachian catheter[1] which I introduced some years ago. This catheter, it may be well to state here, is made of flexible rubber, but is sufficiently unyielding to retain its shape while in use. It has a soft, velvety finish, and its introduction in the adult creates so little discomfort that one which is one-fourth of an inch in diameter can generally be employed. This is readily introduced into the mouth of the Eustachian tube, and permits a large current of air to pass. I proceeded to introduce a catheter of the above-mentioned size through the inferior nasal passage, and after connecting it with a large metallic ear syringe by means of a stout piece of soft rubber tubing ten inches in length, suction was effectually established by using the syringe as in aspiration. It was worked by one hand whilst the other hand kept the catheter in place. By means of an otoscopic tube the suction in the affected ear could be plainly heard by myself with each pumping stroke of the piston, the action being yet more plainly manifest to the patient, who after one or two successful exhaustive efforts had been made exclaimed, "That does the work; the pain has gone." Suction was

[1] Wide Trans. Am. Otological Society, 1881. The catheters are made by Mr. Ford, of Caswell, Hazard, and Co.

Digitized by Google

then maintained until half a dozen strokes of the piston were made. Relief from the disagreeable tension and other symptoms was not only immediate, but it was also permanent, although the deafness, autophonia, &c. did not entirely disappear for some days. No local injury was inflicted by the catheter on the mucous membrane of the pharynx; and on examination of the membrana flaccida, it was found that its convexity was much reduced and the congestion diminished. In the previous attacks of acute inflammation of the middle ear, to which Professor Bryant has been subject, the disease has frequently gone on to the suppurative stage, and the membranes have spontaneously ruptured or were punctured. In the present instance suppurative action was probably prevented by the timely withdrawal of the secretions from the tympanum. The only medication in the case consisted of the administration, subsequent to the operation, of sulphate of calcium, in doses of one-twentieth of a grain, every three or four hours, and small doses of the fluid extract of belladonna and aconite. Even these mild measures were somewhat neglected, and the patient gave himself no rest during the attack; on the contrary, he not only attended to his practice and college work, but also made a journey out of town. At the date of the present writing, he states that he has felt entirely well for more than a fortnight.

MIDDLESEX HOSPITAL.

POISONING BY CARBOLIC ACID; SEVERE BRONCHITIS; RECOVERY; COMMENTS.

(Under the care of Dr. SIDNEY COUPLAND.)

FOR the notes and comments in this case we are indebted to Mr. L. M. Guilding, M.R.C.S., late resident physician's assistant.

A well-nourished, healthy little boy, aged three years and a half, was admitted into Cambridge ward on Aug. 16th, having taken half an hour previously a small quantity of a solution of crude carbolic acid used for disinfectant purposes. His breath smelt strongly of the acid, and there were some excoriations about the lips. He was in a state of extreme collapse, with cold clammy extremities; shallow laboured respiration, and all but pulseless. In the out-patient room four drachms of ipecacuanha wine and a small enema of beef-tea and brandy had been administered, and after being put to bed hot-water bottles were placed to the feet and in the axillæ. As the emetic took no effect, a hypodermic injection of apomorphia, one-tenth of a grain, was tried. In a few minutes the child made an attempt to vomit, his mouth and nostrils became clogged with yellowish mucus, his face grew livid and cyanosed, and he was all but asphyxiated. His throat was swabbed out, and the natural colour in some degree returned. The general depression, however, was much worse, and the child seemed hovering between life and death. Pulse thready, fluttering, and scarcely perceptible; respiration 99, very laboured; loud mucous râles audible over the whole of the chest, and his motions passed under him in the bed. Ten minims of ether were injected subcutaneously into the arm. A second enema, containing two ounces of beef-tea and half an ounce of brandy, was administered per rectum, to be repeated every four hours, and a linseed jacket poultice was ordered. Under this treatment he rallied, and at 10 P.M. was sleeping quietly, to all appearance free from any danger beyond a severe attack of bronchitis. Respiration 66; pulse 120; temperature 102·6°. His urine was passed under him in the bed, so that it was impossible to examine it for evidence of the poison. Vomiting at intervals through the night, but vomited matter did not contain blood.

Aug. 17th.—Respiration had diminished in frequency to 36, but the physical signs of bronchitis remained unaltered. He passed a comfortable day, but towards the evening was seized with severe dyspnœa and became very cyanosed. Respiration 100; pulse 120. He was ordered an expectorant mixture with ten minims of spirit of sulphuric ether and five minims of antimony wine every four hours. Curtains round cot; steam kettle; linseed poultices to be continued. Ordered two drachms of brandy in enema every four hours, and half a drachm by the mouth every hour. 12.30 A.M. Respiration more tranquil, and cyanosis greatly diminished; but the child was so restless that it was found impossible to keep him covered up. Temperature 102·4°.—18th: The child passed an extremely restless night, but was evidently much better. Respiration 72; pulse 120; temperature 101·4°. Bronchitis still severe, but unaccompanied by expectoration.

From this date the child made steady progress towards convalescence. The medicine and stimulants were gradually withdrawn, and on Aug. 25th he was allowed ordinary diet. His recovery was marked by extreme restlessness and a vacuous, almost idiotic expression. He could not be induced to speak until two days before his discharge on Sept. 1st.

Comments.—The following points with regard to the case are of interest:—1. Where a rapid and efficient emetic is required ipecacuanha wine is practically worthless on account of the time it requires to act, and possibly owing to the fact that unless the bottle containing it is well shaken, little but sherry is administered—a practical point often forgotten at the moment. Apomorphia is efficacious, but depressant to a dangerous degree. As an emetic nothing surpasses the household remedy of mustard-and-water. The sulphates of copper or zinc are equally good. 2. In cases of carbolic poisoning in children the main effort should be to arrest the dangerous state of shock and collapse which is invariably present, and to apprehend a severe attack of bronchitis and give it prompt treatment. This is a distinct fact which has been well exemplified in several cases admitted of late into the hospital. For apart from its immediate local effect, carbolic acid appears to be very liable to excite broncho-pulmonary irritation; and fatal cases of pneumonia due to carbolic poisoning are sometimes witnessed. Again, in the present case the long-continued condition of mental depression which supervened was remarkable, and must be attributed either to the initial "shock" or to the direct action of the poison on the brain.

LIVERPOOL ROYAL INFIRMARY.

VILLOUS TUMOUR OF BLADDER; REMOVAL BY [illegible] CYSTOTOMY; DEATH; REMARKS.

(Under the care of Mr. REGINALD HARRISON.)

F. J. M——, aged forty-two, married, engaged in business, was admitted on Sept. 8th, 1884. In December, 1880, without any apparent cause, he commenced to pass blood in his urine. In December, 1882, he first came under Mr. Harrison's observation. Three months previous to this a catheter had been passed for him, which was followed by a considerable increase in the amount of blood and vesical irritation. For this condition, rest and various styptics were tried with some improvement. Matico seemed to answer best; turpentine increased the vesical irritation. In January, 1883, a piece of growth was passed by the urethra and proved to be villous; on subsequent occasions similar fragments were expelled along with the urine. The infusion of matico was of service to him, and at times he had a cessation of hæmorrhage for periods of six and eight weeks. In the summer of 1883, in consequence of the persistence and amount of hæmorrhage, Mr. Harrison urged the desirability of direct surgical interference, but the patient, who had by reason of his business considerable knowledge of drugs, preferred waiting. In July, 1884, the amount of blood passed was excessive, and he became extremely blanched and exhausted. In September his condition had become still more extreme, and he requested that an attempt should be made to get at the growth. It was clear that unless the bleeding was stopped he could not survive but a few days.

On Sept. 10th he was placed under ether and Mr. Harrison opened the bladder by the median perineal incision. To give more space for manipulation the spot and part of the prostate were incised vertically by a probe-pointed knife, an addition to the ordinary method of entering the bladder from the membranous urethra which has proved valuable. The growth was readily felt and a large portion of it

Digitized by Google

removed by forceps and a scoop. The bladder was much distended with blood-clots, and these had to be cleared away before the tumour could be defined. The patient's condition rendered it necessary that the manipulation should not be prolonged. The amount of blood which escaped from the incision and tumour was very small, and no vessel required a ligature. One of Browne's dilatable tampons was introduced and the patient removed to bed. He seemed to be rallying nicely, urine escaping both by the tube and the side of it. Death occurred somewhat suddenly, apparently from syncope, twelve hours after the operation.

An examination of the bladder after death showed the pedicle and remains of a villous tumour, occupying the position of the orifice of the left ureter, the orifice of the right ureter was patent and dilated, as if blood had been forced into it; the bladder was hypertropied, not sacculated, but rather more capacious than natural. The prostate was normal and the incisions into it were as described. The pedicle of the growth in the relaxed condition of the parts occupied the mucous membrane of the bladder round about the orifice of the left ureter to an extent that a shilling would cover; when constricted with a ligature the space occupied was reduced to one-fourth of this; by means of a ligature the entire connexions of the growth (which in its original state was about the size of an ordinary hen's egg) could be included. Had it been possible to apply it, the ligature would probably have been the most effectual method of dealing with the growth. There were no signs of secondary deposit in any of the parts subjected to examination in the neighbouring glands.

Remarks.—Mr. Harrison observed that all cases bearing upon the operative treatment of tumours connected with the bladder or prostate should be reported regardless of results, in order that the value of the treatment may be duly estimated and the indications for operation more precisely determined. He could hardly imagine a more favourable case for operation than the one just described had such measures been resorted to earlier. The tumour was of at least four years' growth, was a true villous, and had no features which clinically could be regarded as typical of malignancy. The patient died, not from any ulcerative action, or cachexia, or from the spread of the growth, but from the continuance of a hæmorrhage it was found impossible to restrain by medicines. In this instance additional room for entering the bladder from the membranous urethra was afforded by incising in the median line directly upwards and downwards the roof and floor of the prostate. The necessity for attempting to remove, either entirely or partially, tumours occupying the interior of the bladder or the prostate will be determined by the nature of the symptoms they produce; here it was undertaken with the object of arresting a hæmorrhage under which the patient was rapidly sinking without any other chance of escape. Mr. Harrison referred, in illustration of the sudden and excessive bleeding that tumours of this nature are liable to, even when they may appear comparatively quiescent. In a case he had recently published,[1] where death from this cause took place in nine hours, in this instance slight hæmaturia had existed for some months previously, but no operation had been performed.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Nerve Symptoms in Rheumatic Affections.—Preputial Calculi.—Urticaria Pigmentosa.—Perforation of Vermiform Appendix.

THE first meeting of the session was held on October 10th, Sir Andrew Clark, President, in the chair. The attendance was numerous, and considerable discussion was elicited by the papers read by Dr. Hadden and Dr. Finlay. In the course of the evening the President congratulated Dr. C. Theodore Williams on his reappearance amongst them.

Dr. W. H. HADDEN read a paper on Certain Nerve Symptoms in Rheumatic Affections. The first case was one of glossy skin following on an acute joint affection. The patient, a woman aged thirty-five, was under the care of Dr. Bristowe at St. Thomas's Hospital. A year before admission she was attacked with articular rheumatism which lasted for six months. She was jaundiced for six weeks after the attack. A month before admission she had rheumatic pains in the knees, back, and hands. On examination no swelling or tenderness of joints was found, but she complained of rheumatic pains in various parts. All the fingers of the right hand were extended, the fore and middle fingers were wasted and sensation a little impaired. She could only flex them very slightly, but could bend the ring and little fingers more readily. She could not separate the fingers of the right hand so well as those of the left. All the fingers of the right hand were wasted, smooth, and shiny, and the nails were long and filbert-shaped. There was atrophy of the muscles of the forearm and of the thenar and hypothenar eminences. She rapidly recovered under the use of the continuous current. The second case was that of a young woman, aged twenty-six, who had had swelling and tenderness of various joints, but chiefly of the right fingers, for a week before admission. She complained chiefly of two small round superficial sores, one on the extensor surface of the second joint of the right little finger, and the other on the extensor surface of the left middle finger, near the base of the nail. They appeared about the time the joints became affected, were very tender and itched a good deal. During the last six months the catamenia had become irregular, and this fact seems to support Dr. Ord's idea that there is a relation between menstrual disorders and joint affections. The third case was that of a man aged fifty-seven, who was the subject of chronic rheumatoid arthritis of some months' standing. His face was curiously expressionless, and the whole body was held stiffly, with a marked forward inclination. The skin of both hands was smooth and shiny. The ends of the finger joints were much thickened, and there was extensive dislocation of joints. Both of the hands were flexed at the metacarpo-phalangeal joints, but the fingers were hyper-extended. There was slight affection of some of the larger joints. There was very extensive anæsthesia of both upper extremities. The prick of a pin was not felt over the front and back of the left leg and the dorsum of the left foot, but elsewhere in the lower limb there was no impairment of sensation. The interossei and extensors of both forearms were atrophied. They responded to the interrupted current, but less actively than normally. The left extensor communis digitorum gave the "reaction of degeneration." The skin and tendon reflexes were exaggerated everywhere, and there was double ankle clonus. The gait of the patient was spastic; an extension of the inflammation from the joints to the nerves might partially account for the various nerve disorders, but the author believed that it was more likely that there was an independent rheumatic neuritis. The nerve disorders were neither concerned with the causation of the gouty affection nor dependent on it. In the first two cases the trophic disorders occurring during the subsidence of the gouty affection seemed to be a relapse affecting the nerves. The author referred to a case of anæsthesia in the course of the ulnar nerve, which he had observed in a patient convalescent from acute rheumatism. The muscular atrophy, affecting chiefly the extensors, seemed to be trophic. In shoulder-joint disease the wasting of the deltoid, and in hip-disease the wasting of the glutei, supported the law that the extensors suffered more than the flexors. It was urged by some that this depends on some selective action of the spinal cord, but the cases of lead palsy and alcoholic paralysis, in which the disease is due to the peripheral nerves, renders it possible that in joint affections a similar cause holds good. The occasional occurrence of rigidity and ankle clonus, perhaps, depends on affection of the spinal cord, although the author believes that such conditions are sometimes due to lesion of the peripheral nerves. The duration and intensity of the joint affection has nothing to do with the cause of these trophic disorders. The cases given neither support nor disprove the theory of articular rheumatism.—Sir ANDREW CLARK believed that in chronic rheumatism, osteo-arthritis and chronic gout disorders of sensation and motion were very frequent; he had never seen the glossy skin in chronic rheumatism, but frequently in osteo-arthritis and chronic gout.—Dr. T. BARLOW briefly related four cases which bore on the subject. The first case was one of acute rheumatism in a man aged forty; a severe attack of rheumatic fever was followed by hyperpyrexia, after which he was found to be affected with anæsthesia in the tract of the ulnar

[1] Liverpool Med. Chir. Journal, July, 1884.

Digitized by Google

nerve, with some wasting of the interosseous muscles of the same side; these nervous conditions soon passed away. The second case was similar to the first, but the amount of wasting was more considerable, so that it looked like progressive muscular atrophy. The third case occurred in a very stout lady, who had an attack of rheumatism; here also the ulnar nerve suffered, and there was wasting of the interosseous muscles. The fourth instance was that of a boy aged fifteen, who was afebrile when first seen; there were signs of mitral obstruction and a history of previous rheumatism; here the nervous symptoms could only be explained by a lesion of the brachial plexus high up in the axilla, since anæsthesia and atrophy were so extensive and irregular in distribution. The degenerative reaction was obtained for a few days only, and the case finished by recovery. A rheumatic inflammation of the sheaths of the nerves was the probable explanation of the above cases, though in the first instance an injury might have played a part, since the man was so violent as to require the strait-jacket.—Dr. LONGHURST inquired whether any evidence of syphilis was present; this was answered in the negative.—Dr. STEPHEN MACKENZIE said that many instances of arthritic inflammation were ascribed to rheumatism, but he could not disregard the possibility of the joint affection and the nervous lesion being due to disease of the spinal cord. He had seen a very remarkable case, which began as one of acute febrile disease, and was diagnosed as acute rheumatism; but when Dr. Mackenzie first saw the case the character of the inflammation of the joints was not like that of acute rheumatism. Incontinence of urine and sacral bedsores appeared, and slight reaction of degeneration was detected in some muscles. The girl made a complete recovery, and there could be no doubt that the symptoms were due to an acute affection of the spinal cord. Chronic and degenerative changes were credited with the power of producing arthritic disease. A definite local lesion of the spinal cord was possibly present in these acute cases without involving the theory that rheumatism was dependent on disorder of the spinal cord.—Mr. HOPKINS narrated a case of absolute paraplegia, during the course of which both knee-joints and ankle-joints were inflamed; there was rapid wasting of the muscles. The patient recovered considerable power, but the joints remained stiff, and the muscles gave no reaction to the faradaic current.—Dr. MILLER ORD referred to a paper read before the Society some years ago in which he had pointed out the agency of the nervous system in the production of arthritic changes. Nodosities of the fingers brought about by uterine affections were possibly due to a reflex nervous influence. Many of the so-called rheumatic affections of joints might be explained by reflex trophic changes produced by the intermediate action of the spinal cord, or again, primary affection of the nervous centres might be the cause of trophic changes in the joints. Charcot had published cases of arthritis of slight, not painful, character, which were followed by atrophy of muscles excessive as compared with the joint lesions. In chronic rheumatoid arthritis the trophic changes might be referred to the intermediate action of the spinal cord. He thought there were many cases which observers were too apt to class as chronic rheumatoid arthritis, which probably owned a neural origin. It was important to recognise that inflammation of joints was common to many conditions.—Dr. HADDEN, in reply, said that it was clear that some observers had met with anæsthesia in cases of rheumatism. He had seen trophic lesions in gout, such as unilateral sweating and glossy skin. No accidental pressure existed in any of the cases he had seen, and so he regarded Dr. Barlow's first case of anæsthesia as of rheumatic origin.

Mr. JOHN CROFT read a brief paper on Preputial Calculi in the Inhabitants of the Fiji Islands. He pointed out that the proportion of males which suffered from phimosis was very great. The calculi were numerous, and composed chiefly of phosphatic matter.

Dr. RADCLIFFE CROCKER showed the drawing of a case of Urticaria Pigmentosa which occurred in a girl aged four and a half months, who came as an out-patient to University College Hospital on September 22nd, 1883, with a history of the affection having commenced when she was three weeks old, coming out first as tubercles singly or in groups. Each tubercle was the size of a small pea, of a yellowish-brown colour with a pink areola; on some of them a small bulla formed, the contents of which became absorbed in a few days, leaving a permanent tubercle of yellowish-red colour; some of them grew larger, and the older ones paler, forming lesions varying in size from a hempseed to a bean, and in colour from a brownish-red to a pale-fawn, but mostly yellowish; they were not pruritic at first, but later on itched at the period of evolution. They covered every part of the body, including the palms and the soles, but were thickest upon the trunk and neck; a few shrunk a little, but most remained unaltered, except that fresh vesicles formed on some of them; there were never any ordinary wheals, nor was factitious urticaria present. The child died of whooping-cough and bronchitis in May last, but signs of improvement in the skin had commenced about a month before death. In reviewing this and the other nineteen published cases, Dr. Crocker summarised the facts known about the condition, and remarked that while cases like Dr. Tilbury Fox's worst and his own were very unlike urticaria, the intermediate cases brought it into closer relationship with that disease; moreover, nearly every one of the special features of urticaria pigmentosa were seen in exceptional cases of ordinary urticaria. The remarkable point was that in this disease all these rare symptoms combined in one individual to form a definite clinical variety.

Dr. D. W. FINLAY communicated a paper on a case of Perforation of the Vermiform Appendix, with Peritoneal Abscesses, followed by death from Pyæmia after a long interval. The patient, a baker, was admitted into the Middlesex Hospital on Jan. 4th, 1884. He complained of severe pain over the whole abdomen, which was moderately distended, tender, and tympanitic. The areas of liver and splenic dulness were normal. The heart and breath sounds were normal. The tongue was dry and coated, with a brown strip down the centre; the cheeks flushed; the lips dry and cracked. The pulse was 96, compressible; the temperature was 99·6°; the respiration 24, and entirely thoracic. The urine was turbid with lithates, and very acid, sp. gr. 1034, free from albumen and sugar. The patient had a similar attack three years previously. Otherwise his health had been good. His present illness came on a week before admission with griping pains across the lower part of the abdomen, followed by vomiting, headache, and diarrhœa. He was treated with opium, and put upon a diet of milk and beef-tea, and three days after admission appeared much better; the general tenderness of abdomen had disappeared, but there was a spot midway between the costal margin and iliac crest on the left side, where tenderness remained, and the percussion note was dull. On Jan. 9th his bowels were opened for the first time after admission, the motions being loose and light in colour, with a few small scybalæ. During the night he had been seized by pain in both parotid regions, and this was followed by swelling and tenderness, with inability to open the mouth. Both swellings suppurated, and were incised; his temperature slowly rose, and he became delirious, and sank somewhat suddenly on Jan. 16th. He had had no rigors. At the post-mortem examination three large and as many small abscess sacs were found within the peritoneum, the oldest-looking being around the vermiform appendix, which was perforated about half way from its attachment. The appendix was plugged by a small mass of fæcal matter on the cæcal side of the perforation. The peritoneal surface generally showed old fibrous bands and greasy-looking flakes uniting the coils of intestine together, with some recent injection, but almost no recent lymph. The other organs were fairly normal, except that the lungs were œdematous, and the left pleura contained a quantity of clear serous fluid. The case seemed interesting from the prolonged latency of the disease, the perforation of the appendix having probably taken place on the occasion of the previous attack, adhesions being then formed which prevented for the time a fatal result. It was certain, at all events, that the abscess sacs were of very considerable age, and it was a striking fact that the man should have been able to go about his daily work apparently in good health with such a condition of his abdominal cavity.—Dr. MAHOMED had for some time directed his attention to the subject of the recurrence of perityphlitic attacks. In the majority of such cases we had to deal with a concretion in the appendix vermiformis. He had thought of performing some operation for removal of the concretion, and had practised the procedure on the dead body. The case of a man was referred to who had suffered from frequent attacks of perityphlitis, in whom the operation had been carried out with complete success. The operation was like that employed for ligature of the external iliac artery; by this means the vermiform appendix could be seized by the finger and felt through the parietal peritoneum; a neat

Digitized by Google

incision on to the calculus contained in the appendix would serve to liberate the concretion. He admitted that cases which perforate into the pelvic cavity were more difficult to deal with. The value of being able to diagnose whether the perforation had taken place into the peritoneal cavity or was more limited was next dwelt upon in its relations to the operation referred to. A physical sign had been pointed out by Professor Austin Flint. This sign was loss of the hepatic dulness in cases of perforation into the peritoneal cavity, and Dr. Mahomed could testify to its correctness. In reply to Sir Andrew Clark, he said that the calculus was mainly a phosphatic concretion.—Dr. THEODORE WILLIAMS referred to the case of a young man who was the subject of phthisis, during the progress of which he one day felt a sharp pain in the right iliac fossa, which was due to a localised peritonitis, as the further history showed. Later on the patient died of pneumothorax, and then the localised abscess was found to have been dependent upon ulceration of the vermiform appendix, which had not led to extensive mischief. The abscess was enclosed completely within a small area, and he thought that surgical interference might have been less satisfactory. He would not be anxious to proceed to the operation proposed by Dr. Mahomed until it was probable that the mischief would be more severe if left to nature.—Mr. HOWARD MARSH thought the suggestion made by Dr. Mahomed was valuable. Nothing could be smaller than the beginning of cases of perityphlitis, which not rarely went on to a fatal termination. He thought the operation would become an acknowledged one. The relation of the appendix to the peritoneum might vary; in his experience it was sometimes behind and outside the peritoneum, but in the majority it was probably within the peritoneum, and had a mesentery of its own. Where the operation could be done without opening the peritoneal cavity, every surgeon ought to perform it. But the difficulty no doubt was how to diagnose the relations of the appendix. Brief mention was made of a case in which perityphlitis, the result of perforation of the appendix, was diagnosed, but in which the patient was too ill to be operated upon. Perforation of the small intestine a few inches above the ileo-cæcal valve was discovered at the autopsy.—Mr. BRYANT was of opinion that in cases of cæcitis the suggested operation, or something akin to it, should be performed more frequently than it was. No doubt, such cases commenced in the connective tissue around the cæcum or vermiform appendix, and early surgical treatment directed to let out the pus, would prevent the suppuration extending far upwards and downwards, thus taking away the worst aspect of the affection. If the surgeon made an incision into the connective tissue of the part, he felt sure that it was the right method. He had tested the possibility of the procedure on the cadaver, and in three cases in the living subject. But he agreed that the question of diagnosis was the trouble. In this relation, he pointed out that associated with this inflammation pain travelling along the anterior crural nerves was not infrequent, and simulated hip disease, for these was also flexion and rotation outwards of the thigh. Again, forced extension produced pain in the cæcal region in such cases.—Mr. CHRISTOPHER HEATH considered that an important sign by which it could be determined whether perforation had taken place within or without the peritoneum was the presence of surgical emphysema; gentle palpation sometimes detected a sensation of crackling in the iliac fossa, and then the perforation was outside the peritoneal cavity.—Mr. R. W. PARKER related the case of a boy who went to the Hospital for Sick Children because he could not pass urine. It appeared that he had received a blow in the loin. Great pain was followed by vomiting, which ended in death. It would seem that a local peritonitis had been induced by a concretion in the appendix having perforated, and that the vomiting had led to the development of general peritonitis, from which the patient rapidly succumbed. This case illustrated how dangerous and unsuspected such concretions were.—Dr. MAHOMED wished it to be understood that he would not operate during the acute stage of the malady, but only when the mischief was quiescent.—Dr. LONGHURST made some remarks on the frequency with which perityphlitis recurred. In one patient there had been five attacks in the course of two years. A means of prevention of the recurrence would be of great service.—Dr. FINLAY, in reply, said that in cases of intestinal perforation obliteration of the hepatic dulness was well known at Middlesex Hospital, and perforation from enteric fever was almost always attended with this sign.

The following living specimens were shown:—Congenital Tumour of the Shoulder, by Mr. Barker; a case of Endarteritis Obliterans, by Mr. Pearce Gould; a case of Bullous Iodide Eruption, by Dr. Radcliffe Crocker; and a case of Pseudo-hypertrophic Paralysis with Contracture of the Thigh, by Dr. T. Barlow.

OPHTHALMOLOGICAL SOCIETY.

Central Choroiditis with Good Vision.—Pseudoglioma and Purulent Meningitis.—Effects of Bisulphide of Carbon and Chloride of Sulphur.—Recent Detachment of Retina.—Night Blindness.—Action of Hydrochlorate of Cocaine.

THE first meeting of the session 1884–85 was held on October 9th, Mr. Jonathan Hutchinson, F.R.S., president, in the chair. Sir William Bowman, Bart., was unanimously elected an honorary member. A committee consisting of Messrs. Nettleship, Green, and Adams Frost was appointed to inquire into the prevalence and nature of impaired sight and nervous affections resulting from the exposure to the fumes of bisulphide of carbon and chloride of sulphur as met with in the manufacture of certain kinds of india-rubber.

Dr. BRAILEY read a letter which had been received from Mr. R. G. Hamilton, stating the steps which the Local Government Board for Ireland had taken in response to the resolution passed by the Society on July 12th in reference to the prevention of blindness. A circular letter had been sent by the Secretary of the Local Government Board for Ireland to the medical officer of each dispensary district, to the midwives of each district, and to the clerk of each union.

Mr. NETTLESHIP showed a drawing of a very remarkable case of Central Choroiditis, with almost perfect acuteness of vision. The choroid over the whole of the yellow-spot region was superficially atrophied, and to a great extent covered by large densely black patches of pigment. The retinal vessels were normal, and the optic disc healthy. There were a few detached patches of pigment beyond the yellow-spot region. Vision was $\frac{20}{30}$ fairly, and 1 Jaeger. No scotoma could be made out, but the visual field was defective at the periphery. The appearances were those of superficial choroiditis, with great proliferation of the pigment epithelium, and infiltration of some of the pigment into the retina. Such changes, involving the fossa centralis, would seem to be incompatible with such good vision as the eye preserved. Two alternative explanations were suggested: either that a slightly eccentric fixation had been acquired, or that the choroiditis had in reality occurred in the deepest larger layers of the choroid. But the fact that the pigment masses lay in front of the large choroidal vessels militated against the latter view.—Mr. WARREN TAY asked to what cause the choroiditis was probably due.—Mr. NETTLESHIP regarded hæmorrhage as the most likely explanation; there was no history of syphilis. In answer to Mr. Hutchinson, he affirmed that the field of vision was a little contracted.—Mr. HUTCHINSON commented on the remarkable extent and severity of the disease involving the fossa centralis, with the preservation of excellent vision.—Dr. ANGEL MONEY referred to a similar case which had been under the care of Mr. Tweedy at University College Hospital.

Mr. NETTLESHIP read a paper on Pseudoglioma followed by death from Meningitis, and said that in a previous paper attention had been drawn to the frequency with which attacks of destructive ophthalmitis, simulating glioma, coincided with some general illness, often presenting pyæmic symptoms. The patient, a girl aged two years and a half, died of cerebro-spinal meningitis, secondary to purulent otitis. The disease of the eye, which was purulent iridocyclitis, with suppuration of the vitreous, was most probably pyæmic, as was also the meningitis. The case threw some light on the rare cases in which meningitis occurs after excision of an acutely inflamed eyeball; both occurrences might be set down as local pyæmia, or spreading phlebitis. If, however, pseudogliomas in children were really the result of a pyæmic process, it was necessary to assume that children recovered from pyæmia with considerable frequency. The previous history of the patient in this case was negative. She was taken ill on March 2nd, shivered, vomited, and had some diarrhœa. The eye was noticed to be inflamed on

Digitized by Google

March 3rd, and she was brought to the hospital on March 5th, when purulent inflammation of the left cornea was noted, and a mass of semi-transparent lymph, blocking the pupil and lying in flocculi in the anterior chamber, was detected. On the following day the temperature ranged between 102·2° and 103·6°, and there was a small firm swelling over the head of the right fibula. On the following day both knees were slightly swollen and tender; the lymph was disappearing from the pupil and the anterior chamber of the left eye; there was marked papillitis of the right eye. The left eye subsequently shrank rapidly, and the patient died of exhaustion six weeks after admission. The necropsy revealed no important lesions, except in the brain and spinal cord. The cura cerebri, optic tracts, and chiasma, the pons, and fore part of the cerebellum, were covered with thick yellowish-white lymph; the roof of the middle ear on the right side was yellowish and softened, the membrana tympani was softened and partially detached, and the middle ear and mastoid cells contained much thick pus. The whole posterior half of the cord, from the upper dorsal region downwards, was covered with yellowish lymph. In reply to the President, Mr. Nettleship said that no phlebitis could be demonstrated.—Dr. ANDERSON referred to the frequent association of cerebral abscess with ear disease without any discoverable tract between the two affections.

Mr. NETTLESHIP also read a paper on Amblyopia and Nervous Depression resulting from the Vapour of Bisulphide of Carbon and Chloride of Sulphur. In the manufacture of certain kinds of indiarubber the material is "cured" (vulcanised) by being passed through a bath consisting of bisulphide of carbon (thirty-two parts) and chloride of sulphur (one part); a strong vapour arises during the process, and the work is believed by the men to be unhealthy. Mr. Nettleship said that he had recently met with a case of amblyopia in a young man, aged twenty, who had been engaged in the "curing house" for about nine or ten months. After about three or four months of the work his health began to fail; he felt great weakness in all his limbs, and a liability to nausea; for some weeks before admission he had severe headache, and about three weeks before admission his sight became, apparently suddenly, so bad that he could not see people on the pavement; vision grew worse, and when admitted vision was $\frac{6}{60}$ with each eye, and 12 Jaeger. He stated that he saw worst in bright daylight; the fields of vision were not curtailed. After admission, improvement commenced, and on the nineteenth day vision was $\frac{2}{3}\frac{4}{0}$ on the right, and $\frac{1}{3}\frac{6}{0}$ on the left; the optic discs were pale, and there was a filmy haze over them; the neighbouring retina showed the "watered silk" appearance. He returned to work in the indiarubber works, but not in the curing-house, on leaving the hospital on Aug. 25th. On October 6th sight was a good deal improved (vision was $\frac{2}{3}\frac{4}{0}$ and 6 Jaeger); there was a large and ill-defined scotoma for red, a little to the outer side of the centre of each field; the scotomata were quite symmetrical. The optic discs were paler and clearer. He was well and strong, and more cheerful. Dr. Ernest Fuchs, Professor of Ophthalmology in the University of Liège, who had happened to see the above case, had communicated to Mr. Nettleship the notes of a similar case. The patient was a young girl, aged twenty-three; she was pale, thin, and weak; the muscles of the thenar eminence and the interossei muscles were atrophied; sight was very imperfect; right vision was $\frac{3}{6}\frac{5}{0}$, left $\frac{4}{6}\frac{5}{0}$; there was slight neuritis of each eye; the optic discs were pale and hazy, but not swollen. The patient stated that since she began working with the bisulphide of carbon bath she had suffered from weakness of the limbs, coldness, formication, headache, giddiness, and loss of appetite. She was admitted into the hospital, and slowly improved under treatment with strychnine administered hypodermically. About eight weeks after admission it was noted that there was a small well-defined central scotoma for red in each eye. Sixteen weeks after admission sight had much improved, vision $\frac{4}{15}$. About seven months after admission the scotoma had disappeared, and right vision was $\frac{5}{7}\frac{5}{7}$, left $\frac{5}{6}$. Eight months and a half after admission the optic discs were paler than normal, but sharply defined; the atrophy of the interossei and thumb muscles had disappeared; vision had improved; right vision $\frac{5}{6}$, left $\frac{4}{6}$. Mr. Nettleship, commenting on the cases, referred to a similar case which had been recorded by Dr. Alexander Bruce; in this case the man lost his sight rapidly after an unusually prolonged exposure to the fumes, but there had been previously for some months great nervous and muscular weakness; there were no ophthalmoscopic changes, and the patient entirely recovered in about four months. Dr. Bruce had also recorded two other cases of poisoning by bisulphide of carbon, in which the same weakness and depression were noticed, but not amblyopia. The cases were of great interest in Mr. Nettleship's opinion, as illustrating in a new way the peculiar liability of the optic nerves, as compared with other nerves of special sense, to be damaged by influences which depress the whole nervous system.—Mr. HUTCHINSON asked whether any inquiries had been made of the manufacturers to ascertain whether the injurious nature of the process of "curing" with bisulphide of carbon and chloride of sulphur was well known.—Mr. NETTLESHIP believed that but few men were engaged in that particular process, and could not give a decided answer to the question.

Dr. W. A. BRAILEY read a paper on the Treatment of Recent Detachment of the Retina founded on three cases. The first patient was a man, aged forty-three. The eye was previously normal judging from the history and from the condition of its fellow. A complete detachment of the retina had apparently occurred fourteen days earlier, during a severe fit of coughing. Gradually perception of light returned, till, on admission, he could count fingers at a foot. When he presented himself six days later for treatment by scleral puncture, vision was $\frac{6}{7\frac{5}{0}}$, and the field very much larger than before. Indeed, no detachment was now to be made out, but there were large opacities in the vitreous, especially near the seat of detachment. This improvement was maintained when last seen, three months later. The second case was a boy, aged twelve. The retina was detached at its upper and outer part, probably after a blow from a stone three months earlier. The lower and inner part of the field was wanting, the defect passing the horizontal line above and the vertical meridian below. It just embraced the fixation point. The retina so far reapplied itself after treatment by scleral puncture, rest, atropine, and jaborandi, that, except for some little peripheral limitation, corresponding to the seat of the previous detachment, the only absolutely blind part was a band or track extending directly inwards to the fixation point, which it involved. This band corresponded to the lower edge of the detachment as first seen ophthalmoscopically; but that edge of the retina lay, when the patient was last seen, in a flat fold. Two weeks later, the improvement was still maintained. The third case was a man, aged forty. The defect first appeared six months before admission, when he was suffering from a violent cough. It gradually increased till September 25th, when he was sent to Guy's Hospital by Dr. Reynolds, of High Wycombe. Then the inner half of the field was wanting, the defect extending beyond the fixation point and vertical meridian above, but not quite so far below. He was able only to count fingers at eight feet. After scleral puncture, atropine, jaborandi, and eight days in bed, the field was conspicuously enlarged, the fixation point being now free. Vision was $\frac{6}{6\frac{5}{0}}$; nor could any detachment be made out any longer; but there were numerous floating opacities in the vitreous, especially near the seat of the detachment. Dr. Brailey remarked that since in at least two out of the three cases the eye had been presumably normal, the detachment would appear to have occurred in association with a healthy vitreous. He found it impossible to understand how either a blow or any violent pressure on the globe could cause a detachment under such circumstances without rupture of the retina, of which he had not been able to find indications in these cases. The rupture would, he thought, be more reasonably attributed to the recoil of the tunics than to the original pressure. The value of the treatment was demonstrated in the third case, where the affection was progressing up to the time of operation. Though valuing puncture, rest, and atropine, he was not convinced as to jaborandi. He thought, in face of these two cases, that a simple puncture, if large enough, was quite as effective as any more complicated process; and, indeed, that it excelled the latter in rendering anæsthesia unnecessary. A bent iridectomy knife, five millimetres wide, seemed to him to be the most effective instrument.—Mr. NETTLESHIP spoke of the case of a man, the subject of myopia, in whom a retinal detachment had occurred very rapidly. In this case tapping was performed, and the patient made to lie on his back. Great improvement followed, and the operation was repeated with still further improvement, but two months later he came back as bad as ever, and the other eye had become similarly dis-

Digitized by Google

eased. He had tapped in many cases, but this was the only one in which even temporary improvement was obtained.—Dr. BRAILEY, in reply, pointed out that Mr. Nettleship's case was myopic, whereas his own were not, the sound eye being normal in every respect.

Mr. W. ADAMS FROST read notes of two cases of Night-blindness. The first was that of a painter, aged thirty-four, who had had six attacks of night-blindness, each coming on whilst he was painting white houses in the spring, the weather, except on two occasions, being very bright. Each attack lasted about a fortnight, and disappeared under treatment by rest, tonics, and the use of eserine. Vision during the attacks was $\frac{3}{24}$, and the visual field was normal. The patient was somewhat anæmic, but there was no history of any illness. He was in receipt of good wages, and had not been underfed. He had never had any symptoms of lead-poisoning, nor had he ever been out of England. The second was that of a lamplighter, aged nineteen, who for six weeks had been engaged in painting the lamp-posts on country roads in excessively bright weather. After three weeks' painting he suffered severely from pain and lacrymation. Three weeks later he suddenly found that he could not see one evening, and this inability to see in a dull light continued until his visit to the hospital two weeks later. His vision then, in ordinary daylight, was normal ($\frac{1}{20}$ and 1 Jaeger), the visual field was normal. He presented no signs, and had had no symptoms of lead-poisoning. He was treated with tonics and instillation of eserine, and recovered in about five weeks. A month later he had a relapse, from which he recovered in about a fortnight. Since the previous attack he had been following his ordinary occupation of lamp-lighting.—Mr. WALTER H. JESSOP had observed patches on the conjunctivæ in cases he had seen. The patches looked like small bubbles of air, and were easily scraped off. On these dry patches numerous bacilli of uniform size were found. These observations had been noted by Mr. Snell and others. Two of the children were underfed, one nearly starved, and the third case was that of an adult male suffering from albuminuria. Artificial cultivations from two cases showed the same characters, and the growth was perceived to be a very slow one. The dry patches disappeared at the same time as the night-blindness.

Mr. ARTHUR BENSON (Dublin) read some observations on the Action of Hydrochlorate of Cocaine on the Eye. He had experimented with a 2 per cent. and a 4 per cent. solution on himself and about twenty-five other individuals. He found that anæsthesia of the cornea and conjunctiva was produced by a drop instilled into the conjunctival sac; that this anæthesia came on almost immediately after its application, and lasted only about five or six minutes, when it gradually but rapidly faded away. He considered that, as far as his experience went, the drug was of no appreciable assistance in operations, the anæsthesia being too imperfect. In most cases it produced slight paresis of accommodation, with partial dilatation of the pupil for about half an hour, followed by contraction of the pupil and spasm of accommodation, which again gave way to the normal condition in about one and a half or two hours. He had extracted cataract, done iridectomy and some minor operations with its aid, but found no appreciable benefit except in the most trivial cases. The anæsthesia was very transitory, and it was therefore necessary in order to obtain the best results to use the drug very shortly before operating.—Mr. MARCUS GUNN had employed hydrochlorate of cocaine in these cases, and had come to the same conclusions as Mr. Benson.—Mr. NETTLESHIP had tried it in two cases; it had produced marked anæsthesia without any inconvenience, and he suggested that, if the drops were frequently instilled so as to maintain the effect, the drug might be practically useful.

DR. BRAILEY showed living specimens of (1) Detachment of the Retina of the Left Eye, decidedly improved after scleral puncture, and (2) Optic Neuritis with increased Tension (relieved by eserine) associated with numbness of the face and recent severe pains in the head, some loss of power in the left side and slight albuminuria; the vision had deteriorated.

As card specimens Mr. NETTLESHIP showed a drawing of new formation of Pigment on the front of the Iris, and Mr. MARCUS GUNN a peculiarly shaped Eyeball, the inner part of the fundus being bulged so as to produce hypermetropia to the extent of 3 D, while the outer part of the fundus corresponded to myopia of 4 D.

ABERNETHIAN SOCIETY.

A MEETING of this Society was held at St. Bartholomew's Hospital on Oct. 9th, when an introductory address was delivered by Dr. J. WICKHAM LEGG. He began by pointing out that in all education there were two kinds of knowledge to be imparted: first, the mere storing of facts; secondly, the digestion and assimilation of facts—the first a mere exercise of the memory, the second the exercise of the higher faculties of the mind. For the first there were the lectures, demonstrations, class examinations, medals, and academical rewards; while for the second there was at St. Bartholomew's the Abernethian Society, in which the student who had learned his facts was taught to ponder over and reflect upon the ideas that he had gained; the Abernethian Society being, in fact, an intellectual gymnasium in which the mind was trained and exercised, just as it was in the disputations and exercises of the mediæval universities. In conclusion, Dr. Legg pointed out the decay of real university training that had followed of necessity in the wake of the examination system—the superficial smattering encouraged by what he called dissipation of mind, not progress in knowledge; and the introduction of which into England was one of the many evils for which the University of London would have to be responsible.

Reviews and Notices of Books.

Injuries and Diseases of the Jaws. The Jacksonian Prize Essay of the Royal College of Surgeons of England, 1867. By CHRISTOPHER HEATH, F.R.C.S., Holme Professor of Clinical Surgery in University College, London, and Surgeon to University College Hospital; Consulting Surgeon to the Dental Hospital. Third Edition. London: J. and A. Churchill. 1884.

WE regret that we have been unable to notice at an earlier date the appearance of the third edition of Mr. Heath's well-known work on the Jaws. The fact that the essay in its original form gained the Jacksonian prize testifies to its high order of merit, and the zeal and ability with which Mr. Heath has subsequently prosecuted his studies in this department of surgery have made this third edition a valuable exposition of our knowledge of diseases and injuries of the jaws. The gross characters and the physiological peculiarities of tumours of the jaws have always made them a subject of special interest to surgeons, and the enlarged information on these growths which Mr. Heath is able to give in this edition deepens the reader's interest. The main alterations in this edition are those which have been made necessary by the advance of pathological research. Thus Mr. Heath has adopted the view of the multilocular cysts of the lower jaw propounded by Mr. Eve, who regards them as arising by epithelial growths starting in the gum, and not as of dental origin. The microscopical characters of the tumours removed by Mr. Heath in recent years are added to the clinical histories of the cases; and a valuable chapter on diseases of the temporo-maxillary articulation has been appended, which makes the work far more complete than heretofore. The work has long held its place as the standard authority on the surgery of the jaws, and this third edition will not only strengthen its position but must add to the reputation the author has already won in this department of practice.

Manual of the Dissection of the Human Body. By LUTHER HOLDEN, late President of the Royal College of Surgeons of England, Consulting Surgeon to St. Bartholomew's and the Foundling Hospitals. Fifth Edition. Edited by JOHN LANGTON, Surgeon to, and Lecturer on Anatomy at, St. Bartholomew's Hospital; Member of the Board of Examiners, Royal College of Surgeons of England, &c. London: J. and A. Churchill. 1884.

MR. HOLDEN'S works have always been favourite text-books with English medical students, and this is largely due to the fact that they are more easily read and understood than

Digitized by Google

any similar works in the English, or indeed in any foreign, language. Mr. Holden writes simply and clearly because he has a definite and precise idea of what he intends to write, and the student understands Mr. Holden fully because every statement is definitely and clearly put. There is not an involved sentence, or one capable of being misunderstood, in any of his writings. The popularity of his Human Osteology has somewhat overshadowed his Manual of Dissections, but the same easy style runs through both. For a companion to the higher student in the daily work of the dissecting-room we should still advise Professor Ellis's well-known treatise as superior in minuteness and accuracy of detail, but to the average pupil for whom such details are unnecessary and frequently too burdensome, the present volume cannot be too highly recommended, and the surgical hints which are interspersed lighten the task of the student and make the work itself more interesting. The new edition has been entirely revised by Mr. Langton, is enlarged by about 200 pages, and contains thirty new woodcuts. It is only due to Mr. Langton to add that while the anatomical descriptions are much more detailed and many important omissions have been supplied, the work has lost nothing in readableness or style. The publishers are to be congratulated on the appearance of the book: in binding, clearness of type, and well-defined illustrations it leaves little or no room for improvement. We only question whether it is not too elaborately finished for the student to keep by his side in the dissecting-room.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

THURSDAY, OCT. 9TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

THE adjourned debate on Sir Henry Pitman's motion for sanctioning the combined scheme of the Royal College of Physicians of London and the Royal College of Surgeons of England was resumed.

Mr. COLLINS said he could not vote for the motion, as he considered the scheme to be opposed to the convictions he had entertained for years past with reference to medical reform. His opinion was that a tripartite board was what was really needed in the three divisions of the kingdom, a combination of the corporations to be joined or not, as might be thought best by the universities. He believed that the universities had determined that it was better for them not to co-operate in such a scheme, and in that opinion he entirely concurred. It was an open secret that the Society of Apothecaries in England and Apothecaries' Hall in Ireland were the real difficulty in the way of a corporate union in those countries. Happily the Scotch corporations had arranged a corporate union and combination satisfactory to themselves and to the Council, and he did not despair of such a union between the English and Irish corporations. The time would come when all the corporations would have to look the question steadily in the face. The Society of Apothecaries of London was a body that could not be ignored in any measure of medical reform, for more than half the medical practitioners in England were amongst its licentiates. As to the Apothecaries' Hall of Ireland, he thought some misapprehension existed with reference to its status and rights. He knew that it was connected with a drug establishment, and if he was asked after an experience of forty years whether that was a wise arrangement ninety years ago, he should say that he believed it was, and that it continued to be so. It was no new thing that the College of Physicians in Ireland had put its corporate foot down upon Apothecaries' Hall, but its action had been unheeded by the Irish Legislature itself when sitting in Dublin, and by the Imperial Legislature down to the present time. It was time that there should be some wise and harmonious combination beneficial to the bodies themselves, to Ireland, and to the United Kingdom. With regard to the proposed scheme, he considered that it was in many respects an excellent one. As to the primary examination, he had more than once expressed his opinion that it was insufficient and incomplete as far as general practitioners were concerned. He was sorry to find that the fees were not to be lowered and brought into harmony with those of the Scotch corporations. In order to do away with unpleasant rivalries, he thought it would be desirable that there should be as nearly as possible a uniform standard of fees in the three kingdoms. He could not vote for Sir Henry Pitman's motion because he thought it would hinder a larger and better system of medical reform in England and Ireland.

DR. DUNCAN said he dissented from the conclusion drawn by Mr. Simon that the Council ought not to sanction the scheme until it was ascertained that the College of Physicians had power to refuse its single qualification. No such remark was made when a similar proposition was made by the Scotch bodies and sanctioned by the Council. The matter was one for the College of Physicians alone to settle, and no doubt when the sanction of the Council had been given that College would consider the subject in all its bearings.

Dr. STORRAR said the Council was not justified in refusing its sanction to the claim simply because it did not include the Society of Apothecaries. The Act empowered them to sanction the union of "any two or more colleges or bodies;" and as two bodies had proposed to combine, he saw no reason for refusing the sanction of the Council simply because they had not included a third. The question raised by Mr. Simon was not a question for the Council, but for the College of Physicians, to settle. As to the desirability of the universities taking part in the examination, no body had been more ready to go out of its way for that purpose than the University of London. But there was really no prospect of medical legislation, and if they could not get all they wanted, why not accept all that they could get? He thought it would be folly to wait for further legislation, which reminded him of Goldsmith's line:—

"Remote, unfriended, melancholy, slow."

Sir HENRY PITMAN said that the amendment condemned as wrong for the College of Physicians that which it regarded as right for the College of Surgeons in reference to the power of withholding qualifications. That was not equal justice, giving to one body what was denied to another. He thought that Dr. Quain could hardly know the meaning of the words "a partially qualifying body." The College of Physicians proposed to co-operate with the College of Surgeons, and its licentiates would have to obtain the diploma of that body. Dr. Quain laid great stress upon the fact that the licence of the Royal College of Physicians was a double qualification, but the idea that when it was granted the same document put into the hands of a candidate who had passed a better examination became only a partial qualification was one that he could not comprehend. The singular contention appeared to be that it was a full qualification before it was granted, but when granted under altered and better conditions it became a partial qualification. Let the Council take care not to pronounce that which was untrue, which it would be doing in passing the amendment. As to the amount of the fees, that was a matter for the bodies themselves to decide. If either of them chose to charge fifty guineas for its licence it would not require the assent of the Council. The argument as to inconvenience appeared to him to be a childish one. Was it really a serious inconvenience for a candidate to go to the College of Surgeons to be examined in surgery instead of being examined in Pall-mall?

Dr. HAUGHTON said it did not appear that the College of Physicians had been under any particular pressure in making the proposed arrangement. It appeared to have the entire approval of the majority of the Fellows, and, under those circumstances, he, as a stranger, was bound to consider that they had discounted all the points of opposition that had been raised, and that he ought not to refuse his sanction to the proposal. All that the College of Physicians proposed to do was to ask a particular group of competent examiners to conduct the surgical part of their examination, and he did not see how such a request could be refused.

Dr. HERON WATSON said that the question was one appertaining to the two Colleges, and the proposal appeared to be strictly within the lines of the Act of 1858,

Digitized by Google

Clause 19 giving a right to two or more bodies to combine. The Council, he thought, had no right to withhold its approval of such a combination, unless it believed that there was something behind the scheme which would be injurious. The representatives of the two Colleges sat at the Council, and had stated that the scheme had the approval of both those bodies, and, under all the circumstances, he thought that the arrangement was one which should be sanctioned.

Dr. STRUTHERS thought that the objections to the present scheme equally applied to the old English conjoint scheme, under which, no less than under the former, the College of Physicians divested itself of some of its powers. It was true that some persons were still clinging to the old English scheme, but it was in reality impossible and impracticable. In Scotland they not only disapproved of it, but they would not have it. The present scheme was workable and viable, which the other was not. As to legislation, no such Bill as that which was presented last year was possible. It was all very well to talk of obstruction in the House of Commons, but it was the intelligence of the House of Commons that would stop any such Bill. Government itself was satisfied that no such measure could pass. He did not believe any Bill could ever pass the House of Commons that did not contain the proposal made by Sir Lyon Playfair, or that superseded existing qualifications as instruments of registration. He thought it was essential that each body should retain the right to admit those who had already received the qualifications of other bodies. The great thing was that single qualifications should be stopped. The division of the examinations under the proposed scheme was an admirable arrangement. Hitherto, when a student was rejected in one subject he was rejected in all, but that would no longer be the case.

Mr. MACNAMARA said he did not know of a more genuine curriculum than that presented in the proposed scheme. The scheme was not, as had been alleged, "a sham," and as to the talk about "the battle of the shops," that might be left to the anonymous medical journalism of London. What was proposed was a bird in the hand, which would be much better than doubtful birds in a distant bush.

Dr. HUMPHRY maintained that under the proposed scheme there would be three examinations less than before and one examining board less.

Dr. LYONS objected to the scheme for its coldness and caution. It was, he said, tentative and halting, and wanted the characteristics of a courageous and trusting proposal. It would have been more promising if it had been more generous and had included bodies that were now left out in the cold. Those bodies would agitate until they were admitted, and the Legislature if necessary would come to their aid. The object of Parliament was to create a large body of well-educated men—educated up to a moderate standard—with a view of providing for the great wants of the State. At present there were 8000 or 9000 herbalists in the country, and there were no means of dealing with them. Government was hopeless in the matter, and it sought the aid of the medical bodies. Under such circumstances he should like to see the leading bodies in England and Ireland coming forward and offering their help, and endeavouring to find some common ground on which all could unite with a view of producing a qualification that would be suitable to all classes of the community, meeting the wants of the large body of men who were now treated by those outside the ranks of the profession. It was not wise to overlook the means they had of thus assisting the State in its endeavours. Each corporate body should be willing to give up something in the general endeavour to meet the requirements of the State in that direction. He hoped, therefore, that the proposed scheme would be sent back to the College of Physicians and the College of Surgeons with a view of seeing in what way they could better accommodate themselves to the great and crying wants of the State. What advantage did the State derive from the union of two bodies like the College of Surgeons and the College of Physicians? How could such a joint body render more assistance to the State than the two bodies could separately? It might be said that their example would be followed by others, and perhaps in Ireland. That might be so, but the example set to Ireland was not a good one. Nothing satisfactory could be accomplished until they found some *modus vivendi*, in the nature of a joint qualification, in which the apothecaries would be allowed to share under such reasonable safeguards as might be recommended.

Dr. QUAIN said that a curious point might arise on the proposed scheme. A person might come with a qualification in medicine from Scotland and go to the College of Physicians asking to be admitted. They would say, "You must go to the College of Surgeons and pass your examination there." He then produced his qualification in surgery from Scotland and they would refuse to examine him. The question was whether if a man had a double qualification he would be admitted by the English College of Physicians and the English College of Surgeons without further examination.

Mr. MARSHALL said he thought it was very unlikely that a man who had held a double qualification in Scotland would come to the English bodies, but such questions were mere matters of detail, and could be settled by the committee of management under the direction of the two Colleges.

Dr. QUAIN said that the two Colleges were not only in union with one another, but with all the medical and surgical qualifying bodies in the country whose licentiates they would have to admit. As to the approval of the scheme by the College of Physicians, he might be allowed to say that that body now knew a great deal more about the subject than when it was first hurriedly brought before them, when they were carried away by the golden colours in which the formation of a great "national board" was proposed. He believed that if the subject were now brought before the College they would reject the proposal as unanimously as they had before accepted it. He maintained that he was correct in stating that under the scheme the College of Physicians would be a partially qualifying body, because it went outside its own walls to get a qualification.

The amendment was then put, and rejected by thirteen votes against five.

Dr. CHAMBERS moved, "That the proposal of the Royal College of Physicians of London and of the Royal College of Surgeons of England to co-operate under the direction of the Council receive the sanction of the Council, provided that full facilities be afforded to the other licensing bodies in England to co-operate with the above-named Colleges under the direction of the Council." He said that when he first saw the scheme he hailed it with greater pleasure than anything else that had occurred since he had been on the Council, because he thought that it was a progressive step towards his El Dorado, the union of all the licensing bodies of England into one. But he was alarmed to hear the statement of Dr. Struthers that such a thing was impossible. He could not accept that view, and he hoped that some assurance would be given that the proposed scheme was not to be a final one, but that facilities would be offered for the union of the other licensing bodies to form a joint examination board for the whole of England, thus setting a good example to Scotland and Ireland. He would be quite willing to sanction the measure in order that it might be carried out to its legitimate conclusion.

Sir HENRY PITMAN said he could not, on the part of the College of Physicians, assent to Dr. Chambers's amendment, which was a proposal to compel the affiliation of one or more other bodies without any knowledge as to the conditions under which it was to take place. The Act of Parliament gave power to the Council to sanction the co-operation of any two or more bodies, but it did not give it the power to force all the bodies into affiliation.

Mr. MARSHALL said he could not accept the amendment on the part of the College of Surgeons, and he should feel it his duty to vote against it.

Dr. HERON WATSON thought that the amendment was entirely uncalled for. A definite scheme was laid before the Council, which it was asked to sanction, and it had nothing to do at present with other bodies.

Mr. SIMON said he confessed to being one of those referred to by Dr. Storrar as hankering after the old scheme, the loss of which he regarded as a misfortune to the prospects of the medical profession in the country. He had never heard it suggested by any Englishman that the scheme had been thrown aside because it was unworkable, and until the present scheme was brought forward he had not heard that any of the authorities who had entered into the old scheme had withdrawn from it on that ground. When the scheme of the Colleges of Physicians and Surgeons was first brought forward the old scheme was still in force. The diminished scheme now submitted had some good points about it. The curriculum and the educational examination appeared to be a great improvement, and there was a great deal in them for

Digitized by Google

which the profession might be thankful. He objected to the scheme not because of its positive provisions, but because of its extreme insufficiency. Only two of the bodies were represented, and he regarded it as a great misfortune that the universities were not co-operating. The corporations would, he thought, be greatly strengthened in their work by the assistance of the universities, especially in the management of the examinations. The spirit of the universities was in his opinion twenty years younger than that of the corporations, and their absence from the scheme seriously endangered the management of the examinations. But a much more serious matter was the absence of one medical corporation; that he considered a great blot upon the scheme. The Apothecaries' Society was omitted, and was, he believed, in a condition of protest, and under those circumstances it was difficult for the Council to say that it could unreservedly approve of the scheme. It should not be forgotten that the Society of Apothecaries was called into existence on account of a neglect of duty on the part of the College of Physicians, which distinctly refused to charge itself with the education and examination of the general medical practitioner. The Society of Apothecaries undertook that duty, and for many years it was the body which contributed in a most important way to improve the status and education of the general practitioner. The College of Physicians was peculiarly bound to be tender to the Society of Apothecaries, and to refrain from any endeavour to thrust it aside. He heartily rejoiced in the approximation of the two Colleges; but he agreed with Dr. Chambers that the Society of Apothecaries ought not to be unhandsomely treated, and that facilities should be offered to them to join the combination on reasonable terms. It had been said that the combination was intended to put an end to inconvenient competition; but would that result be brought about if the Society of Apothecaries was forced to stand alone as an examining body in London, retaining as it would its legal rights to have its licentiates placed on the Medical Register? The result would in reality be an inconvenient competition. He believed that for some purposes the combination would in reality be strengthened by the inclusion of the Society of Apothecaries. There were departments of practice in which its experience might be of use even to the College of Physicians and the College of Surgeons. He suggested that the proposed scheme might be sanctioned on the understanding that the two Colleges shall not be at liberty to refuse the further co-operation of any other of the licensing bodies if offered on terms which the Council thought proper.

Mr. BRADFORD said he was thankful to Mr. Simon for the honourable mention he had made of the Society of Apothecaries, and he hoped that in any conjoint scheme that might be sanctioned by the Council due opportunity would be afforded for the co-operation of that Society, which he believed it was generally admitted had acted liberally and beneficially towards the profession at large, and which he had no doubt would continue to exercise the same salutary influence.

Dr. DUNCAN said there was nothing in the scheme itself that was hostile to the inclusion of the Society of Apothecaries, and he believed that every member of the Council would be glad to see some mode of bringing about that result. It was not, however, to be supposed that that feeling of justice was universally entertained in the profession, for extensive support was given to a Bill which omitted entirely the Societies of Apothecaries in London and Dublin. He opposed the amendment, and supported the original motion. He hoped never to see the union of all the licensing bodies in any of the kingdoms, for he thought that would be the worst possible conclusion that could be arrived at. The evils of the one-portal system were greater than any advantages which it possessed.

Dr. STRUTHERS said that some of them had not a very pleasant recollection of the Apothecaries' Society, to whose influence it was due that medical practitioners in England were in some respects behind those in Scotland, none of whom kept shops. It was considered in Scotland that the practice of charging by drugs was a degrading system, combining, as it did, a trade and a profession. Of course, it was desirable to unite all the corporations if possible, but there were no doubt difficulties in the way.

Mr. MARSHALL stated, in answer to a question by Mr. Macnamara, that a person holding the diploma of the Society of Apothecaries would, under the proposed scheme, be in the same position as persons admitted by the College of Surgeons for examination.

Dr. CHAMBERS, in reply, said that he could not accept the suggestion made by Mr. Simon.

The amendment was then put, and rejected by fourteen votes against four.

Dr. LYON proposed another amendment: "That the scheme of the two Colleges be referred back to them with a view to taking into consideration a scheme including the Apothecaries' Society of London." He said an impression seemed to prevail that the Legislature was not likely again soon to step in to interfere with the work of the Council, but he did not himself share in that opinion. The subject was one offering great attractions to the Legislature, and he did not think that the next session would be very far advanced before a note would be sounded announcing the advent of a new Medical Bill. It was certainly "within measurable distance."

Dr. HAUGHTON said that the two Colleges had no doubt looked at the matter on all sides, and he considered it was a waste of time to discuss the matter further. He thought that a triple scheme would be best, but still an enormous advantage would be gained by the public and the profession by the union of the two great medical bodies of England. He therefore gave the scheme his hearty support, hoping that hereafter some wise proposals would be made and accepted for the admission of the Society of Apothecaries.

The amendment was put, and rejected by sixteen votes against four.

Mr. BRADFORD moved another amendment: "That after the last word of the original motion the following be added—'on the understanding that the two Colleges shall not be at liberty to refuse the further co-operation of any other of the English licensing bodies if offered on terms which this Council deems proper.'"

Sir HENRY PITMAN, in opposing the amendment, said he objected to any conditions being attached to the sanction of the Council to the proposed scheme. There was apparently an attempt on the part of certain members to crush or prevent any laudable desire or effort by the two great corporations of the kingdom to carry out what the Council had been for years encouraging them to attempt. For many years the Council had been recommending that certain steps should be taken, but their recommendations had been disregarded, and now certain members of the Council were very sensitive when two Colleges simply asked the sanction of the Council to put into practice what had long since been approved in principle.

Dr. QUAIN protested against any imputations being cast upon the members of the Council. (Cries of "Vote, vote.")

The PRESIDENT then, in the midst of some confusion—several members rising to speak—put the amendment, which was rejected by fourteen votes against six.

The original motion was then put and carried.

The Council then adjourned.

FRIDAY, OCT. 10TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

The first business was the consideration of the Report by the Pharmacopœia Committee.

Sir HENRY PITMAN moved that the Report be received, and entered on the minutes and adopted.

Dr. QUAIN seconded the motion.

The Pharmacopœia Committee beg leave to report that they have held a meeting since the last session of the General Medical Council in March, and that the subcommittee also met on May 13th, 1884. At the meeting of the Pharmacopœia Committee, held on June 20th, 1884, a summary of suggestions, received in reply to the memorandum sent by their direction to the several medical and other bodies and individuals, as stated in the last report of the committee, presented to the General Medical Council on March 27th, 1874 (see Minutes, vol. xxi., p. 14), was fully considered, with the assistance of the editors, Professors Redwood, Bentley, and Attfield. Directions were then given to the editors to expedite as much as possible the preparation of the Pharmacopœia. The chairman reported to the committee, at their meeting held on July (Oct. 8th), that the Registrar had informed him that the previous edition of the Pharmacopœia was exhausted.

Professor Redwood, who was present, informed the committee that considerable progress had been made with the new edition, especially with regard to new substances and their preparations, the introduction of which the committee had sanctioned, but in reference to which much work yet remained to be done. He, however, reported to the committee, on behalf of himself and his colleagues, that the utmost attention should be used in the preparation of the work.

The committee report that, in connection with this matter, Mr. Macnamara had tendered his resignation as a member of the committee.

RICHARD QUAIN, M.D., Chairman.

Oct. 8th, 1884.

Mr. MACNAMARA, in explanation of the letter which he had sent tendering his resignation as a member of the com-

Digitized by Google

mittee, said that when the committee met in June last it sat from two till six. He, as well as Dr. A. Smith and Mr. Collins, then left, and he was under the impression that they would meet again the next day to consider certain matters which he wished to bring before them, including the question of chemical notation. But when he arrived the next day he was told that during his absence the previous evening the committee had finished all the remaining business in ten minutes. He considered that he had not been treated with the courtesy due to the Professor of Materia Medica in the Royal College of Surgeons in Ireland, and he therefore sent in his resignation.

Dr. QUAIN said that at the last meeting of the Council he stated that it would be most desirable for the Pharmacopœia Committee to meet in June, and in answer to a question by Dr. Storrar he expressed his opinion that the cost would be about £70 or £80. He forgot at the moment that there were more representatives on the Pharmacopœia Committee than on the Executive Committee, and, when he found that the expenses exceeded the sum he had mentioned by about £40, he considered that they could not continue their sittings from day to day without the sanction of the Council. At six o'clock there was sufficient matter left on the programme to occupy about ten minutes. Mr. Macnamara said he would not sit a moment beyond six o'clock, and after discussing the question for about five minutes he went away. A quorum was still left, and they finished the work that had to be done. Mr. Macnamara had told them that he had something to say in reference to nitrate of copper, and out of respect to him they met again next day, though in somewhat an informal way.

Dr. A. SMITH said he took the same view as Mr. Macnamara, and although he received no notice he attended the next day, and he considered that he was entitled to be paid for it.

Mr. COLLINS said that there had evidently been a misunderstanding, but he wished to state that the Irish members of the committee were treated with the greatest courtesy by the chairman, Dr. Quain. When he was informed that there were no funds to pay for a second day's meeting, because the expenditure had already been exceeded, he at once considered that that was a sufficient reason for not having another day's payment sitting. Not expecting that the meeting would last after six o'clock he had made an appointment, and he asked Dr. Quain's permission to retire, adding that he would be quite satisfied with any arrangement that the other members of the committee might make, and that he would come again the next day, and hear what Mr. Macnamara had to say.

Sir Henry Pitman's motion was then carried.

The PRESIDENT trusted that after the explanation that had been given the Council would continue to have the assistance of Mr. Macnamara on the committee. From his own personal knowledge he could state that the Chairman of the Pharmacopœia Committee, who had served the Council with great energy for many years, did his utmost on the occasion referred to to smooth over the difficulty.

Mr. MACNAMARA then withdrew his resignation, and the last paragraph of the report was ordered to be struck out.

Dr. HUMPHRY moved: "That in the opinion of this Council no person should be granted a degree, diploma, or licence to practise, registrable under the Medical Act, unless he has proved his competency in medicine, surgery, and midwifery by passing examinations in those subjects at one or more of the licensing bodies." He said he brought forward this resolution because at the present time he was of opinion the Council should go forward with more energy than they had hitherto shown, and take more definite steps to carry out to the best of their ability the powers conferred upon them by the Medical Act. It had long been one of the recommendations of the Council to the various bodies that no persons should be admitted to the Register who had not passed examinations in medicine, surgery, and midwifery, and that very point had been most prominently brought forward by the Legislature in every Bill for many years past. It therefore appeared to him that that was a matter which the Council should now take up, and upon which they should to the utmost of their power insist. He thought the best mode of doing that would be to send the recommendations again in a definite form to the several licensing bodies, because there were at present on the Register, and others were still getting upon it, persons who had not passed examinations in those three subjects. It was perfectly within the abilities of the Council and the bodies themselves to carry out recommendations without any further legislation, for the Act of 1858 gave the Council the power to appeal to the Privy Council against any licensing body which did not carry out their recommendations. His proposal simply was that the recommendation should be again sent to the bodies, who should be left for the present to carry it out.

Dr. HAUGHTON seconded the motion. He heartily concurred in it so far as it went, but he did not think it went far enough. He was so much afraid that the recommendation would not be carried out that he thought the Council must go further and cut the cancer out by legislation. A man who was most imperfectly qualified to practise but who had passed an examination in one branch of the profession could compel the registrar to put his name down on the Register on production of his licence, and then he could practise every branch of the profession. He had known cases where students in a hospital, finding surgery more attractive than medicine, never entered the fever wards, and therefore would be incompetent to treat a fever patient. For fifteen years he had been in all the parliamentary agitations relating to medical matters, and no member of the Council knew more about "lobbying" in the House of Commons than he did, and he was continually being asked the question by members of Parliament, "Why do you not guarantee that if a man is placed on the Register he is competent to go to any case which is a question of life and death?" Unless that was made compulsory by legislation, he thought some of the licensing bodies would not carry out the recommendation. Though the Council had had the power to compel the bodies to carry out the recommendation, they had never had the moral courage to exercise it. He therefore thought that, however frightened they might be at threatened legislation, something more should be done than merely to pass Dr. Humphry's motion.

Dr. BANKS cordially approved of the motion, for he had long entertained an opinion that a competent knowledge of midwifery ought to be compulsory. So strongly did he feel on the matter, that when he was one of those who had to formulate a programme for the examinations in the Royal University of Ireland, he carried a motion in the face of much opposition to the effect that candidates for the degree in medicine should produce evidence of six months' practice in midwifery. There was no subject upon which so much ignorance prevailed among students.

Dr. STORRAR said he heartily supported the motion, but there was a difficulty connected with it in reference to the position of the Society of Apothecaries of London and the Apothecaries' Hall of Ireland. They had no power by their charters to examine in surgery, and if a man went to the Society of Apothecaries and asked to be examined for a licence as an apothecary he did not see how he could be refused. If he obtained the licence he could demand to be registered. There were only two ways of getting over this difficulty: either the Apothecaries' Society must dwindle down into a condition of absolute effeteness with no candidates presenting themselves for examination, or it must be united with the College of Physicians and the College of Surgeons.

Dr. STRUTHERS said in Scotland astonishment had been expressed that the recommendation had not been enforced. That anyone should be registered who had not been examined in all the three branches was intolerable. The motion was far too mild, and he would propose that the Council should intimate to the licensing bodies that if the recommendation were not carried out an appeal would be made to the Privy Council.

Mr. SIMON said the appeal to the Privy Council could only be made when the Council thought proper examinations were not held for the qualification required by the Act, but the Legislature at the time of the passing of the Act recognised half qualifications as sufficient, and as long as the examination was enough for half qualification, it was not a case for the Council to appeal to the Privy Council. He strongly agreed with the spirit of Dr. Humphry's motion, but there were some difficulties in the way. The Apothecaries' Society would have to appoint a surgical examiner, and he (Mr. Simon) had looked at their Act, and did not see any reason there why they should not do so. It was true that the Council had no power to say that a man should not be registered as an apothecary, but they might say that they did not think it right that a man should be registered without having been examined in surgery, and then it became a question with the Society of Apothecaries whether they could appoint a surgical examiner. If a question were

Digitized by Google

raised in a court of law between the College of Surgeons and the Society of Apothecaries as to the right of the latter to do this, it certainly would be a very strong reply to contend that medicine included surgery, and that as the Society of Apothecaries examined in medicine it was entitled to examine in the humbler branch of the healing art. An equally strong reply would be that its examination would be incomplete as giving a professional qualification unless surgery was included.

Mr. TEALE thought that if the Council would make it impossible for any man to get on the Register unless he had been fully examined in all three subjects, a very important and useful step would be taken. In Scotland the question had already been settled by the union of the three corporations and the previous action of the universities. It was secured in a great measure in England by the union of the College of Physicians and the College of Surgeons which the Council had sanctioned yesterday, and the only point of difficulty in England related to the Apothecaries' Society; but it was for that Society to find a way out of the difficulty. They might appoint surgical examiners, or they might arrange to keep their licence in suspense over those who passed their examination until they acquired a surgical qualification elsewhere.

Dr. A. SMITH thought that the only way in which the object of the Council could be attained would be to ask the Government to pass a Bill of one clause to the effect of their recommendation.

The Council consented to Dr. Humphry's making the following addition to his resolution: "That this resolution be communicated to the several licensing bodies, with an expression of the hope of the Council that each licensing body will use its best endeavours to give effect to it."

Mr. COLLINS said that for a great many years the Apothecaries' Hall of Ireland had made it obligatory upon their candidates to present certificates of having attended at least twenty cases in midwifery. With respect to surgery, the opinion of the late Baron Piggott was that one of the clauses of the Apothecaries' Hall gave a good deal of latitude with regard to the examinations, and when the Council's recommendations arrived the Apothecaries' Hall acted upon that opinion as far as they thought reasonable or possible. On the board of examiners there were now one gentleman who was a Fellow of the Royal College of Surgeons of Ireland, and another who was for a long time a demonstrator in one of the schools of anatomy. These gentlemen had been authorised to examine the candidates to a very great extent in surgery in accordance with the recommendation of the Medical Council. In Ireland a man could not get a position on the Poor-law Board unless he produced certificates of qualification in medicine and surgery, and that was a sufficient safeguard for the general public. There were also upwards of a thousand dispensaries in Ireland, and no practitioner could obtain the appointment to one of them without producing the double licence in medicine and surgery. The whole question showed the importance of forming a tripartite board. At the Apothecaries' Hall there were not the appliances nor the means to examine a man in the higher branches of surgery. According to the recommendation of the Council, at present each licensing body would be turned into a medical university, a thing which was never intended by their various Acts of Parliament.

Dr. LYONS thought it was neither desirable nor practicable to compel every man entering the profession to qualify himself in every conceivable branch of medical education. The Council was now departing from the ancient traditions of the profession, which recognised the cultivation of certain departments by particular individuals, and was running counter to the modern feeling in favour of division of labour. Out of the 22,000 practitioners in the kingdom, there might be 4000 or 5000 who never had any intention of practising midwifery, and he did not think it wise to compel such men to stop in their career and learn a branch of their profession which was distasteful to them, especially when after acquiring the qualification they would never make any use of it. If it was the intention of a candidate to practise midwifery, he should be compelled to obtain a qualification in it, and it might be made penal for any man to attempt to practise midwifery who did not possess a licence in it. That would answer all the requirements of safety on the part of the public, and at the same time relieve those who did not intend to practise it from the labour of obtaining a qualification in it. There were other subjects besides midwifery on which the public mind had been seriously occupied, such as ophthalmic surgery for those who entered the army, and an adequate knowledge of lunacy. He thought that the Council was travelling too fast, and if they intended to legislate in the direction of midwifery they would have to legislate also on the subject of lunacy, and enforce on all who entered the profession a competent knowledge of that subject. He would therefore move as an amendment: "That this Council is prepared to consider a recommendation to Government that the possession of a licence to practise midwifery be rigidly enforced by statute on those persons who enter on the practice of midwifery, and that it be made penal to practise midwifery without such licence, duly obtained after special education and examination."

Mr. COLLINS said he would second the amendment in order to beget a discussion on it.

Mr. MACNAMARA impressed upon the Council the necessity of caution with regard to the exercise of their power of going to the Privy Council.

Dr. MATTHEWS DUNCAN supported the motion. He did not think it desirable to refer back to what was done in 1869, because that would imply a degree of continuity in the history of the Council which the Council did not possess. He approved of the recommendation being renewed at the present time because the Council now had a feeling of responsibility which it did not have in 1869 or 1880.

Dr. BANKS said he could sympathise with Dr. Lyons' remarks as to the necessity of medical men possessing a competent knowledge of lunacy, for in some cases it might be a question of life or death, and a practitioner might have to decide whether the accused person was of sound or unsound mind.

The motion was then put and negatived.

Dr. HUMPHRY briefly replied, and the original motion was then put and carried, only one hand being held up against it.

The following communication was read from the Royal College of Surgeons of England:—

Royal College of Surgeons of England,
Lincoln's-inn-fields, W.C., Aug. 8th, 1884.

SIR,—In pursuance of the requirements of Section 28th of the Medical Act of 1858, I am directed to acquaint you, for the information of the General Medical Council, that the attention of the Council of the College having been directed to the unprofessional advertisements and publications issued by Mr. George Washington Evans, a member of the College, now resident at 41, Cambridge-street, Hyde-park-square, and the Council having duly considered the case, as coming within Clause 2, Section XVII. of the Bye-laws of the College, the following resolution was adopted by them on the 10th ult., and confirmed on the 5th inst.:—

"That in the opinion of the Council the advertisements and publications issued by Mr. George Washington Evans are, in the terms of Clause 2, Section XVII. of the Bye-laws, 'prejudicial to the interests' and 'derogatory to the honour of the College,' and 'disgraceful to the profession of surgery,' and that, in consequence of the issue thereof by him, he be removed from being a member of the College."

I am, Sir, your obedient servant,
W. J. C. Miller, Esq. EDWARD TRIMMER, Secretary.

On the motion of Mr. MARSHALL, seconded by Dr. HUMPHRY, it was agreed, "That the Registrar be directed to remove from the Medical Register the qualification of Member of the Royal College of Surgeons of England, 1865, formerly held by Mr. George Washington Evans."

The REGISTRAR then read the following communication from the Royal College of Surgeons of Edinburgh:—

Royal College of Surgeons of Edinburgh, May 19th, 1884.

DEAR SIR,—I enclose a certified excerpt from the minutes of meeting of this College held on the 16th inst., and in accordance therewith the name of Mr. Thomas Robert Horton has been erased from the list of Licentiates of the College. Yours truly,
W. J. C. Miller, Esq., Registrar of General Medical Council. JAMES ROBERTSON.

"The Royal College of Surgeons, Edinburgh, May 16th, 1884.

"Excerpt from Minutes of Meeting of the Royal College of Surgeons of Edinburgh, held on May 16th, 1884.

"There were then submitted to the meeting the whole documents and correspondence relating to the case of Mr. Thomas Robert Horton, adjourned from the meeting of Dec. 15th, 1883, and the officer having called the name of Thomas Robert Horton at the outer door, and reported that he was not present, the President moved that the College, having resumed consideration of the case of the said Thomas Robert Horton, specified on the billet, together with the certified extract of the verdict of the jury, and sentence, under the hand of H. B. Tayler, Clerk of Arraigns of the Supreme Court of South Australia, and citation of Mr. Horton of May 16th, 1883, along with the letters to Mr. Robertson from Mr. Horton's agent, Mr. Henry C. H. Ayliffe, Solicitor, 85, King William-street, Adelaide, and from himself dated February 15th and March 26th last, and the statements and whole documents transmitted, or referred to in these letters, and it established that the said Thomas Robert Horton was convicted of conspiracy to defraud, and that no sufficient reasons have been adduced by him why the College should not in consequence recall his diploma of Licentiate, dated April 17th, 1879; therefore the College hereby recall the said Diploma, and declare the same to be void, and direct that certified excerpts from this minute, containing this resolution, be transmitted by Mr. Robertson to Mr. Horton,

Digitized by Google

to the Registrar of the General Medical Council, and to the Secretary of the South Australian Branch of the British Medical Association, which was seconded by Dr. Patrick Heron Watson, and unanimously agreed to. "Certified by James Robertson, Clerk." "JOSEPH BELL, Secretary."

On the motion of Dr. HERON WATSON, seconded by Dr. HALDANE, it was agreed, "That the Registrar be directed to remove from the Medical Register the qualification of Licentiate of the Royal College of Surgeons of Edinburgh, 1879, formerly held by Mr. Thomas Robert Horton."

The following communication from the Branch Council was then read, and ordered to be entered on the minutes:—

Branch Medical Council (Ireland),
35, Dawson-street, Dublin, Oct. 3rd, 1884.

DEAR SIR,—In compliance with a resolution passed by the Branch Medical Council for Ireland on the 26th ult., I herewith enclose, for the information of the General Medical Council at their next meeting, copies of the Minutes of this Branch Council for Oct. 15th, 1883, and Sept. 26th, 1884, in which are contained the original resolutions of the Branch Council for Ireland relative to enforcing due attendance on hospital practice by students, and the replies thereto of the Irish medical authorities. Yours faithfully,

R. W. HEARD, Registrar.

W. J. C. Miller, Esq., Registrar of the General Medical Council.

The Council then adjourned.

SATURDAY, OCT. 11TH.

SIR H. ACLAND, PRESIDENT, IN THE CHAIR.

Sir HENRY PITMAN moved, "That the Registrar be directed to send annually a circular to each of the bodies contained in Sections I., II., III. of the list of examining bodies whose examinations for intending medical students fulfil the conditions of the Medical Council as regards preliminary education, for information on the following points, with respect to their examinations recognised by the Council:—(*a*) Highest percentage of marks attained by any candidate; (*b*) lowest percentage of marks obtained by any candidate who passed; (*c*) total number of candidates who passed, and of those who did not pass, at the examination referred to; (*d*) copies of the examination papers set." The list of bodies, he said, was a long one, but he scarcely thought that any of them should be excepted. In regard to professional examination, the Council asked for returns from all alike, and received each year a statement of the number of candidates that passed, the number rejected, and the total number examined at each examination. He now asked for similar returns from the bodies whose examinations in general education were recognised by the Council. The reason for the request would be apparent from the report made to the Council by the College of Preceptors which conducted an examination at which a large number of medical students presented themselves. From that return it appeared that at the examination for the half year ending in March last the number of rejections was three out of four, showing that there was considerable strictness (he did not say too much) in that examination. Whether other bodies were equally strict they could not of course judge, their testamur being accepted without any evidence as to whether it was founded upon sufficient knowledge or not. The candidates rejected at the College of Preceptors might find some other body less strict, and present themselves at their examinations. It was therefore the duty of the Council to exercise some supervision over the preliminary examination as conducted by other bodies. At any rate, the returns which he asked the Council to sanction would afford them a good deal of useful information and place them in a position to deal with the subject at some future time.

Dr. HAUGHTON, in seconding the resolution, said it was of very little consequence to know how many candidates passed or were rejected at any particular examination, which was what mathematicians called "a function of many variables." The thing to be ascertained was the preparedness and intelligence of the candidates and teachers.

Dr. A. SMITH supported the motion. The information sought would be very valuable, and it would be still more so if they had a return of the subjects in which candidates continually failed. The highest percentage of marks was of very little importance.

Sir H. PITMAN thought that the addition suggested by Dr. A. Smith would give unnecessary trouble and complicate the returns.

Dr. HAUGHTON thought that the additional returns suggested would often be illusory, especially at the universities like his own, where examinations were held for purposes outside the objects of the Council, with a view of ascertaining whether the candidates had a sufficient knowledge of Greek and Latin, elementary English and mathematics, to continue a four years' course in Arts.

Mr. MACNAMARA said it would be inconvenient if it appeared that a university examination did not contain all the subjects required by the Council.

Dr. HAUGHTON said that his university examination contained all the subjects, and more. Mechanics, however, was not one of the subjects at the entrance examination, but was taken a year afterwards.

Mr. MACNAMARA sympathised with the desire of Dr. A. Smith to know the subjects in which candidates failed or were weak. Such information could be easily given in the returns of the College of Surgeons of Ireland, a record of such subjects being always kept.

After some further discussion on the precise wording of the resolution, and the desirability of the results of the examinations being uniformly stated, the motion was put and agreed to.

On the motion of Mr. PETTIGREW, seconded by Dr. HERON WATSON, it was resolved, "That the several examining bodies be requested to give the results of their examinations in question (written or oral) by means of percentages.

Dr. STORRAR moved, "That the words 'Executive Committee,' in line 8, clause 6, of chapter 13 of the Standing Orders, be inserted instead of the words 'Branch Council,' to which such applications may be made.'" He explained that the resolution referred to applications made for the registration of persons who had held appointments as surgeon or assistant-surgeon in the army, navy, or East India Service, or had acted as surgeon in the public service or in the service of any charitable institution on or before Oct. 1st, 1828. Such applications, he said, were now made to the Executive Committee, the Executive Committee referred them to the Branch Council, and the Branch Council referred them back to the Executive Committee. His proposal was that they should be dealt with at once by the Branch Councils, instead of by the present circuitous method, in order to save both time and expense.

Dr. STRUTHERS seconded the motion, which, after a brief discussion, was agreed to.

Dr. HUMPHRY moved, "That with a view of giving greater efficiency and continuity to the visitation of examinations, four persons in England, two in Scotland, and two in Ireland be appointed to visit examinations of the licensing bodies during the year." He said he had had experience both as a visitor appointed by the Council and also as an examiner at Cambridge and at the College of Surgeons, London, and had been one of those concerned in modifying the examinations at both those places, and he was of opinion that the power which the Council possessed of visiting examinations was one of the most effective and beneficial powers which it possessed. The result obtained by it was not only to be seen in connexion with the resolutions passed by the Council when the reports of the visitors were considered, but in the influence of the visitors upon the examiners with whom they had conferred, in the communications of the visitors with one another, and, last but not least, in the communications which the visitors had made to their own bodies on their return. By these various means a quiet but most important influence had been going on affecting almost all the examinations in the United Kingdom, but the licensing bodies had no doubt often been quite unconscious of the manner in which the influence had been exerted. Such quiet influence was the very best that the Council could bring to bear upon the licensing bodies, though it produced very little credit to the Council. His desire now was that it should be of a more efficient kind, and that it should be regular and systematic. Of course the bodies were informed that it was going to take place, and that afforded them the opportunity of preparing for it. It also led to a certain amount of nervousness and disturbance in the particular bodies as well as in the candidates. As an examiner he found that very slight things disturbed the candidates. He did not recommend that the reports of visitors should be so long as they had formerly been. If the visitations went on continuously the reports would be shorter, and it would become the regular work of the Council to receive information with respect to them. If his suggestion were carried out the visitors would know not only what was the exceptional manner of the examinations, but also what was regularly going on. It would not be necessary to incur any very great expense in carrying out the proposed plan, but that

Digitized by Google

would depend upon the arrangements made by the Executive Committee.

Dr. QUAIN seconded the motion, and said he thought that the question of expense ought not to be considered by the Council. They ought not to be accumulating money that should be appropriated to present purposes.

Dr. STRUTHERS supported the motion, and expressed an opinion that the visitors should, as far as possible, be experts in the subjects on which the candidates were examined, otherwise their reports would be of little value. A report from himself, for example, on an examination in midwifery or botany would be of little or no value to the Council, but if the subject was anatomy he should know whether it was a difficult examination or not. He thought that members of the Council had a right to be present at examinations, and it would be a good thing if they would occasionally "drop in" in a quiet way to see how they were being conducted. The Branch Councils also had the power of visitation if they chose to exercise it. Visitors, he thought, should be appointed to every examination. It was impossible that the same set of visitors could visit all.

Dr. PETTIGREW also thought that visitations, to be effectual, should be conducted by experts. This was not the case on the last occasion, and the report of the visitors, admirable as it was, had in consequence given rise to some criticism. If the visitations were more frequent and regular the examiners and the examined would be accustomed to them, and there would be no such inconvenience as sometimes arose from their occurrence.

Dr. HAUGHTON thought that the visitations should be confined to the final examinations.

Dr. QUAIN considered that the number of visitors should be left open, but that there should be a sufficient number appointed to visit the examinations during the year, the special arrangements being left with the Executive Committee.

Mr. SIMON thought it would be better to resolve, "That the Council resume its visitation of examinations, and instruct the Executive Committee to conduct the visitations continuously from year to year."

Sir H. PITMAN said that there was already a standing order to the effect that the visitations should be continued systematically.

Dr. BANKS supported the motion, and said that the visitations had been of inestimable value, and had had the effect of raising the character of the examinations. If the Council was fortunate enough to secure such men as were appointed on the last occasion, a great benefit would accrue to the profession.

Dr. HERON WATSON also bore testimony to the good effect produced by the visitations. The Council had hitherto made too little use of a most valuable instrument placed in its hands by Parliament. It would be a great advantage to have the examinations conducted continuously, so that the visitors might have the opportunity of correcting first impressions when necessary. During the last visitation at Edinburgh the visitors could only spend a few hours there, and therefore had no opportunity of knowing the general character of the examination as conducted from day to day during a period of three weeks.

The PRESIDENT desired to emphasise the remark of Dr. Struthers as to the power possessed by individual members of the Council to visit examinations, whether specially deputed or not. Since he had been President he had seriously asked himself whether they ought not to use that power—not in a critical, unfriendly way, but for the purpose of informing themselves of what was going on. He had himself gone to one of the chief examining bodies and asked permission to attend, and he had been received in the most kind and courteous manner, and every information was afforded him, all the more readily perhaps because the visit was not an official one. If they desired they could in that way inform themselves as to any examination going on in the country. They also had the power of deputing other persons than themselves to perform that duty officially.

Dr. HAUGHTON said he had afforded every facility to the visitors at Trinity College, Dublin, but he had been instructed not to part with the custody of the papers, and not to allow any interference with the examination.

Mr. TEALE said that the partial character of the visitation at Edinburgh was owing to the difficulty of fitting in the various visitations, and to the large number of examiners among whom the examinations were distributed. The whole visitation was made under peculiar circumstances, the visitors having been asked to do what had never before been attempted, to visit all the examinations, which necessarily involved an immense amount of work. He did not suppose that such an attempt would be made again. The value of the report was that it contained a comparative statement of the methods employed. The visitations were commenced with the idea that some of the bodies were considerably below the mark in their examinations, and also with the idea of spurring them on and of finding out defects. They had now got much beyond that stage and entering on a new development. The visitors should be selected, not to take, as before, a general view, but to act as experts in the various subjects of examination. They should, he thought, as a rule, be younger men, busily engaged in teaching, and knowing the work of all the schools, so that they could keep the Council in touch with modern education in its various aspects, and enable it with advantage to revise its general curriculum.

Dr. STRUTHERS suggested that the number of examiners should not be less than four for the primary and not less than six for the final examination.

Dr. LYONS, in supporting the principle of the motion, said that the Council had been a little tardy in discharging the obligation imposed upon it; and it would be guilty of a dereliction of duty if it did not, even at so late a period, initiate a satisfactory system of visitations.

The motion was then put and agreed to.

A communication was received from certain dentists at Nottingham with reference to an alleged improper assumption of the name of "Eskell" by a practitioner in that town, an assistant of Messrs. Clifford of London, who, it was suggested, had been guilty of professional misconduct, and were liable to have their names erased from the Medical Register. The Council resolved that it saw no reason for taking any action in the matter.

A communication was received from the Preston Medico-Ethical Society requesting the Council to obtain a parliamentary enactment rendering penal all advertisements offering medical and surgical advice by unqualified persons. The communication was ordered to be entered on the minutes.

A communication was received from the Irish Branch Council expressing its opinion that the General Medical Council "ought at its forthcoming meeting to lay down the general principles upon which an amendment of the Medical Act of 1858 should be constructed."

The Council then adjourned.

MONDAY, OCT. 13TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

Mr. SIMON moved: "That the Council will, at its next ordinary session, reconsider the 'Recommendations' which it at present has in force ('Recommendations,' Chapters III., IV., V.) on the subject of the age for licence for practice, and of professional education and examination; and that, with a view to such reconsideration, the Council now request the three Branch Councils respectively to enter upon a review of the present 'Recommendations,' each Branch Council conferring, so far as it may find desirable, with the several licensing authorities of its division; and that the Branch Councils be requested to communicate to the President, not later than the last day of January next, any suggestions which they respectively may have to make for amendment of the present 'Recommendations.'" He said he proposed the resolution almost as a matter of routine, and not with any prejudice in a revolutionary, or even a mutational sense. A good many years had passed since the last revision of the Recommendations, and it seemed to him essential that the Council should look over them again with such new lights as had been obtained in the interval. There were several points in connexion with the Recommendations about which his opinions were unsettled, and he would be reluctant to form a new opinion without consultation with others, and especially without taking the advice of the local authorities in the different divisions of the kingdom. His proposal was that next session the Council should go into the matter of professional examination systematically. He believed there was a pretty general consensus of opinion against raising the age, but there was a much less decided opinion on the subject of whether or not the curriculum should be extended. As preparatory to the discussion on the matter, it would be well that the Branch Councils should confer with the licensing

Digitized by Google

authorities, and therefore he did not consider that his motion went beyond the necessities of the case.

Dr. BANKS seconded the motion, and said that it covered in a far better way the ground of the resolution which he himself had previously brought forward. His own motion was fragmentary and partial, Mr. Simon's was comprehensive and complete. It was chiefly with a view to the extension of the curriculum that he introduced the subject of the age for licence to practise, and he thought it quite right that the opinions of the Branch Councils and the authorities should be obtained with regard to the matter.

Mr. MARSHALL was in favour of the motion, because it did not bind the Council to any particular line.

Dr. STRUTHERS supported the motion. He would very much like to see the Branch Councils have something to do. A great deal had recently been said about divisional boards, but the Branch Councils would be divisional boards if they only had something to do, and clause 6 of the Act of 1858 enabled the Council to delegate to the Branch Councils everything except representations to the Privy Council. Medical education varied in the three divisions of the kingdom, and there was no reason why all medical men should be passed through the same mould. The only part of the resolution about which he had any doubt was the date by which the suggestions must be sent to the President. He considered that February or March would be quite early enough.

Dr. LYONS drew attention to the last words of Clause 6 of the Act of 1858, which said, "The President shall be a member of all the Branch Councils." He thought that the exercise of the power there given would be attended with very important results. It would give new life and great interest to the meetings of the Branch Councils if the President attended them. Ireland was not favoured with the shadow of great persons, and he hoped that in future the President would not be such an absentee from the meetings of the Irish Branch Council as he had been in the past.

Dr. HALDANE, while concurring in the motion, suggested that it would have more effect if the request were made direct to the licensing bodies instead of leaving it to the Branch Councils.

Mr. TEALE considered the motion was an extremely important one, as it would institute between the three Branch Councils and the General Council a much more intimate consultation than had previously existed. The present was a very important epoch in reference to the revision of the curriculum and the Recommendations. Assuming that the time for medical education was years ago just enough for the subjects that had to be taught, it was clear that for the present extended curriculum longer time was required, and if the subjects were added to materially without extending the time harm must be done somewhere.

Dr. PETTIGREW also supported the motion, considering that the time had come when it was absolutely necessary to reconsider the age for licence to practise. He wished especially to press upon the Council the necessity of allowing the Branch Councils to do a proper share of the work. Everything that could be done by the Branch Councils should be done by them. In each division of the kingdom there were peculiarities of education, and the Branch Councils were specially fitted for dealing with them.

Sir HENRY PITMAN did not desire to offer any opposition to the motion, but it appeared to him to be somewhat imperfect. He would have preferred to see the entire Recommendations, embracing the preliminary as well as the professional examinations, included. The resolution proposed "that the Branch Councils be requested to communicate with the President." No doubt common sense would say that the President would deal with them in any way he though t proper, but it would be better to add words giving power to the Executive Committee to deal with them, and it possible to consolidate them. If similar suggestions, varying perhaps in form, were received from two or more Branch Councils, the Executive Committee might frame them so that they might be brought before the Council in a form in which they could be readily dealt with.

Mr. SIMON said he was very much gratified at the kind manner in which his suggestion had been received. His feelings were entirely in sympathy with what had been said by Dr. Struthers and Dr. Pettigrew as to the desirability of giving greater occupation and a larger sphere of activity to the Branch Councils, and to look upon them, in fact, as divisional boards. A little timidity might be felt lest, if the Scottish Branch Council had too much power, it would excommunicate some of those who lived further south, but within reasonable limits it was desirable to develop the Branch Councils in relation to the General Council and to the licensing authorities. He approved of Dr. Haldane's suggestion, and perhaps words might be added to the resolution to the effect that a copy of the resolution be forwarded to each of the licensing bodies with a request that they would communicate with the Branch Council. Dr. Struthers' suggestion that the date should be February instead of January paid too high a compliment to the Executive Committee at the expense of the Branch Councils.

The PRESIDENT said he had very little doubt that if the motion were carried it would prove to be one of the most important acts that had ever taken place since the formation of the Council. It would carry out the spirit of one of the most important recommendations of the Royal Commission which was introduced into the last Bill—namely, that a portion of the work of the Council should be done by the Branch Councils. Though this might appear to outsiders to be a retrograde step, it really was not so. When the Council first met, what was necessary was that the divers bodies representing different opinions and interests should unite together, but experience had shown that the difficulties of the Council were enormously increased, and that what was often called a waste of time was one of the necessities of the position. What was absolutely wanted for the work of the Council was some arrangement of procedure by which the views of the different bodies and the different nationalities might be brought forward in a state of preparation so that the endless details which arose when matters were brought before them in a crude condition might be avoided. He felt that the whole question of medical education in the near future turned upon some such change in procedure as was now proposed. Before sitting down he wished to thank his Irish friends for the manner in which they had invited him to cross the Channel, but upon that subject he had a revelation to make. Shortly after he became President, being in Scotland, he was invited to attend and preside at a Branch Council's meeting there, and he did so with great satisfaction to himself. He had never refused a similar invitation to Ireland. He had on three or four occasions gone to Ireland with the express hope that he might receive it, but he had not been invited, and he was afraid that if he had himself proposed to attend the Branch Council, it might have an injurious effect, and might not be acceptable. If he could do any good by attending any special meeting of a Branch Council he would consider it his duty to go, and nothing would prevent him accepting the invitation except a feeling that he was not representing the Council for that particular purpose, or that he was not worthy of the confidence of the Council, and in that case he should resign his functions.

The resolution was put to the Council and carried, as was also a motion to the effect that a copy of the resolution should be forwarded to each of the licensing authorities.

Sir HENRY PITMAN moved: "That the Council resolve itself into a committee of the whole Council to enter fully into the consideration of the subject of preliminary education." He said he had felt bound to put this motion upon the agenda in consequence of a report which was presented to the last session of the Council, which said: "Should the Bill now before Parliament become law during the present session the consideration of this subject (preliminary examination) will devolve upon another body; should it not do so it will be the duty of the Medical Council to lose no time in entering fully upon it." He understood from that that it was the feeling of the Council that at the earliest opportunity the subject should come before it; but there were other reasons for pressing it, based partly upon the report from the Royal College of Preceptors. That report showed that only four persons passed in mechanics out of 274 candidates who were examined. The Council must not suppose that those 274 candidates were all medical students, because he apprehended that the examination included men intended for other professions. The Council would also remember that an application was made by the School Boards of Cambridge representing that candidates who had passed what was called the lower examination were recognised, while those who passed a higher examination were not. The Council was asked to grant an exemption, so as to make those two examinations at Cambridge equal, but they had not taken the matter into consideration.

Dr. A. SMITH seconded the motion.

Dr. HAUGHTON held that the cause of preliminary education would be better served and more carefully considered

Digitized by Google

by the Council if it came, like a professional examination, through the Branch Councils. Without sufficient knowledge of the details of the various bodies the Council had yet made general recommendations about preliminary education. Take, for example, Trinity College. There they did not hold a preliminary examination in mechanics and hydrostatics; on the contrary, they required a year's teaching and study of those subjects, and never put them into a preliminary examination. Another year was spent in teaching heat, magnetism, and electricity. The idea of putting these extremely important subjects into a preliminary examination was not in accordance with their practice. He thought the Council had entered too much into small details, and that they should leave a body like that which he represented to teach mechanics and physics in its own way. Why not talk the matter over in the Branch Councils first and then consider it in the Council?

Dr. STRUTHERS was of opinion that it would be better for the Council to make some recommendations on preliminary examinations and then to place the subject in the hands of the Branch Councils.

Mr. MACNAMARA said that if ever there was a subject which the Council ought to discuss it was one which was now before them. If it was shunted, by being referred to Branch Councils, there would be a great difference of opinion in the separate branches as to the amount of preliminary education necessary, and then the matter would have to come back to the Council. Unless some general principle, which would be applicable to the three divisions of the kingdom, was laid down by the Council they would simply be putting off the evil day, for they would have to come to a decision eventually, when the reports came up from the Branch Councils. Let them proceed to the work for which they were summoned and not retreat from a difficulty which they ought boldly to face. He should vote against the suggestion to refer it to the Branch Councils.

Dr. HAUGHTON said he was quite ready to go on if it was the wish of the Council.

The resolution was then agreed to, and the Council thereupon resolved itself into committee.

Dr. HUMPHRY moved—"That, with the view of lessening the area and improving the quality of the preliminary examination, the subjects be as follows:—(*a*) Latin, including translation and grammar, the candidate to have the option of translating a portion from an author previously specified, or easy passages not taken from such author, or both; (*b*) arithmetic, including vulgar and decimal fractions; (*c*) geometry, including the first book of Euclid, with easy questions on the subject-matter of the same; (*d*) elementary mechanics of solids and fluids, meaning thereby mechanics, hydraulics, and pneumatics. The candidate to be required to answer the questions in such a manner as to satisfy the examiners that he has an adequate knowledge of English grammar and orthography." He said that good preliminary education was the corner-stone of their work, while the question of lengthening the curriculum or fixing a period at which a person might become a member of their profession was really of secondary importance compared with the ascertaining whether those who entered it were qualified to commence its study. The proposals he made were four, and he had limited them intentionally to that number in order to diminish the area. It might be said that he had reduced the examinations rather too much, but he would ask the Council to consider that any improvement in quality of a kind which he suggested was equivalent to a considerable diminution of the area. "Latin" was the first part of the motion, his desire being that that tongue should be one of the subjects, and that care should be taken to ensure that the candidate had, through Latin, acquired a thorough knowledge of language. The student, he thought, should have a specified subject. The old plan requiring translations from passages not previously seen, would, in the opinion of many persons, exclude a large number of those who would prove very good members.

Mr. TEALE seconded the motion.

After some further discussion,

Dr. HAUGHTON moved, "That the requirements of the preliminary examination in regard to the subject of Latin be as follows. Translation from two specified authors, one prose and one verse, and easy passages from another author, at the discretion of the examiner."

Dr. HALDANE seconded the amendment.

A discussion ensued with reference to the precise course to be adopted in further considering the question, and the result was that both the motion and the amendment were withdrawn, on the understanding that Dr. Humphry should be allowed on the following day to substitute another motion.

The Council then adjourned.

TUESDAY, OCT. 14TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

The Council went into committee on the subject of Dr. Humphry's motion with regard to preliminary examination.

Dr. HUMPHRY, by permission, withdrew his motion, and substituted the following:—(*A*) "That the motion in Clause 1 of this programme be withdrawn, and that in place thereof the following be substituted: 'That the subjects now exacted for the preliminary examination, as set forth hereunder, be considered *seriatim*—viz., (1) English language, including grammar and composition; (2) English history; (3) modern geography; (4) Latin, including translation from the original, and grammar; (5) elements of mathematics, comprising (*a*) arithmetic, including vulgar and decimal fractions, (*b*) algebra, including simple equations, (*c*) geometry, including the first two books of Euclid or the subjects thereof; (6) elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics;[1] (7) one of the following optional subjects—(*a*) Greek, (*b*) French, (*c*) German, (*d*) Italian, (*e*) any other modern language, (*f*) logic, (*g*) botany, (*h*) elementary chemistry.'—(*B*) That the subjects be modified as follows: '(1) That the candidate be required to answer the questions in such a manner as to satisfy the examiners that he has an adequate knowledge of English grammar and orthography; (2) that English history be omitted; (3) that modern geography be omitted; (4) that Latin include translation from selected authors, and translation of easy passages not taken from such authors; (5) that instead of two books of Euclid there be the first book of Euclid, with easy questions on the subject matter of the same; (6) elementary mechanics, to be passed before registration; (7) that these optional subjects be omitted altogether.'" In regard to his proposal with reference to English, he said he thought the method he proposed for testing the candidate's knowledge was much better than that of a special examination. That method was adopted at Oxford and Cambridge, and by the most recently constituted examining boards. If a person could write English correctly he gave the best evidence of his knowledge of the language.

Mr. SIMON seconded the motion with regard to English.

Dr. STORRAR, in opposing the motion, said he knew that many schoolmasters regarded English as in no respect inferior to Latin or Greek as a means of mental discipline. He would suggest that the Council should go over the list of examinations conducted by universities and other bodies, and see whether any, and, if any, which of them should be eliminated and which should be retained, and then proceed to consider what would be done with those candidates who did not present themselves at the examinations that were retained. He should prefer that all the preliminary examinations be conducted by independent bodies like the universities, but the question was what was to be done for the residuum who went elsewhere.

Mr. MACNAMARA contended that English should be maintained in the curriculum. In Ireland English received great attention as a subject of education. If it were shunted by the Council the schools would take the hint, and English would in future be neglected.

Mr. TEALE said the question was not whether the student should be properly educated to write English correctly, but whether English should be the language on which the educational training should be based.

Mr. SIMON said the object to secure was that a candidate should have a good practical young man's knowledge of English, and that, in his opinion, was best tested in the practical way proposed—by seeing, for example, whether the candidate translated his Latin into well-spelled and properly constructed sentences. The Latin examiners might, indeed, be invited to give special attention to that point.

Dr. DUNCAN supported the motion on the ground that it was sufficient to test the student in one language. He had always understood that English was the worst subject to take for a grammatical examination, and that Latin was the best.

Dr. HALDANE, while objecting to a knowledge of English

[1] "This subject may be passed either before registration or before or at the first professional examination."

Digitized by Google

grammar being made essential, thought that at the same time every student should be tested in his practical knowledge of the language, and that should be done by means of composition and writing from dictation.

Dr. BANKS said that English was lamentably neglected in the schools in the country in which he had the misfortune to live. He considered that such a knowledge of English as every respectably educated person should possess was one of the great essentials for a man commencing the study of medicine.

Dr. HERON WATSON said he should regret exceedingly if Dr. Humphry's resolution was passed by the Council. The object of a preliminary examination was not simply to test the amount of knowledge that an individual had at a given moment on a particular subject—that was only a means to an end; the object they really had in view was to determine whether a young man had really had an opportunity afforded him of having such a liberal education as would fit him for the commencement of his medical education.

Dr. HAUGHTON thought too much importance could not be attached to English. It was the finest language that any man ever spoke; it had the power of expressing any conceivable quantity of ideas and emotions; and in his opinion it would be a shameful thing if the educated classes left its study to School Board scholars.

Sir H. PITMAN was afraid the Council was very likely to fall into an error in this matter. He believed that for years past they had done very well with regard to the matter of English. The purport of the foot-note was to tell the educating bodies the way in which they were to ascertain how a candidate knew the subject on which he was examined. The result was that the Council was dictating to the examining bodies of the great universities of the country, who gave their lives to education, and to that great body to whom they entrusted the conduct of their common examination—the College of Preceptors; they were assuming that those bodies did not know how to conduct an examination in English. Surely, when the Council said that it required a knowledge of English grammar and composition, that was as much as it ought to say, and it should then leave it to the examining bodies to decide how the possession of that knowledge was to be ascertained.

Mr. MACNAMARA said that, while Sir H. Pitman told them they were not to dictate to the examiners, the Council, if it accepted Dr. Humphry's motion, would in fact be dictating in the most absolute way how the examiners were to proceed—namely, not by examination in the English language, but by an examination in other subjects.

Dr. HUMPHRY said his object was that the student should have a better knowledge of English, and he maintained that the mode to obtain that was to give the students a deeper and more careful instruction in one language, that language being Latin.

Dr. QUAIN said if there was to be no examination in English the result would be, that English would not be taught.

Dr. STRUTHERS congratulated the Council on the improvement that had resulted in preliminary education owing to its regulations. He said that before the Medical Act existed some of the examining bodies required no preliminary education whatever. He altogether dissented from the idea that the Council had in any way failed in the matter. He drew attention to the preliminary examinations required from students before entering upon medical studies in Germany and France as showing that those countries were a long way in advance of this country. He was surprised to hear what had been said with regard to this examination in English, for if he were tied down to have one subject only and put out all the others he would retain English composition and German.

Mr. MARSHALL thought that it should be left to the educational bodies themselves to settle the controversy that had arisen. The great object to be secured in future was the introduction of a preliminary scientific education between the early one and the strictly professional course. In the present state of things, however, he could not hold up his hand for the exclusion of English as a special subject for examination. The Council would be backsliding in the matter of education if it adopted Dr. Humphry's proposal.

The PRESIDENT, in putting the motion, said that the study of English had of late assumed an entirely different shape, and if he voted he should do so in such a way as to show his desire to do nothing that would disparage the cultivation of the language.

The proposal was then put, and rejected by sixteen votes against seven.

The Council then sat for some time in private, and documents were read in regard to a registered practitioner against whom a complaint had been forwarded by the Branch Council for Scotland. It was, after some discussion, resolved to leave it to the Executive Committee to take such steps as it might, under legal advice, deem proper for bringing the case before the Council at its next meeting.

Strangers having been readmitted,

Sir HENRY PITMAN said it seemed to him to be impossible to deal with the subject of Preliminary Examinations at the present sitting of the Council. He therefore moved, "That the Executive Committee be requested to consider what changes, if any, are required in the present regulations of preliminary education and examinations, and to communicate with the several Branch Councils on the subject, if deemed advisable, and to report to the next session of Council." He thought it would be far better to leave the matter undisturbed until it could be carefully and properly considered. The Executive Committee might meanwhile gather the combined opinions of the Branch Councils, and then bring up a report to the next meeting of the Council.

Dr. AQUILLA SMITH seconded the motion.

Mr. SIMON thought Sir Henry Pitman had put the Council in rather a false position. They had resolved on his motion to go into committee on the details of the Recommendations; they had been discussing it for some hours; their minds were full of the subject; and now they were asked not to proceed further. He (Mr. Simon) would prefer to proceed, and he thought the Council might make some progress in the matter.

Mr. MACNAMARA and Dr. PETTIGREW having expressed similar opinions,

Dr. STORRAR said his own personal feeling was that the Council was somewhat premature in going into this question at all. It was no very distant period since they had the whole of this preliminary examination under their consideration, and now they were setting to work to alter it again. Such a proceeding would unsettle the public mind, and he should advocate letting things remain as they were.

Sir HENRY PITMAN asked permission of the Council to withdraw his motion, and it was accordingly withdrawn.

A petition was then read from Mr. A. A. Sadgrove, asking that his name might be restored to the Register. He stated that he had been deprived of the privilege of practising for more than eighteen months, which meant a loss of £528 according to the position he previously held. He had since been obliged to refuse some very liberal offers, owing to his name not appearing on the Register. He enclosed a testimonial signed by the medical officers of the Paddington Provident Dispensary.

Strangers were then directed to withdraw; and on the motion of Dr. STORRAR, seconded by Dr. HAUGHTON, it was resolved, "That the Council see no ground for restoring the name of Arthur Augustus Sadgrove to the Medical Register."

It was also moved by Dr. FERGUS, seconded by Dr. SCOTT ORR, and resolved: "(*a*) That information be sent to all the licensing bodies that forged diplomas are in existence, and that this Council recommends the various bodies to be careful as to the recognition of foreign diplomas as admitting to final examinations. (*b*) That in all cases of doubt, or when the person presenting such diploma is not well known, the secretary of the licensing body should communicate with the university by which the diploma is said to have been granted."

The Council then adjourned.

WEDNESDAY, OCT. 15TH.

SIR H. ACLAND, PRESIDENT, IN THE CHAIR.

The Council went into committee for the adjourned consideration of the subject of preliminary examination of medical students.

On the motion of Dr. HUMPHRY, it was resolved, without discussion, that English history should be omitted from the subjects required for the preliminary examination.

Dr. HUMPHRY then moved, and Dr. STRUTHERS seconded, that modern geography be omitted.

Dr. STORRAR protested against the proposed omission, believing that geography was a necessary part of a medical student's education.

Dr. LYONS also objected to the proposal, and said that

Digitized by Google

the subject was peculiarly important to medical men in connexion with the subject of the geographical distribution of disease, and the localities whence drugs are obtained.

Dr. CHAMBERS supported the motion.

Dr. HAUGHTON also spoke in favour of the motion, which was put and carried.

Dr. HUMPHRY moved: "That Latin include translation from specified authors, and translation of easy passages not taken from such authors." He said he did not suggest that the subjects whose omission he proposed were not unimportant ones in the way of mental culture, but what they had to determine was the selection of such subjects as would afford the best means of education. Hitherto the curriculum had been greatly overloaded, and the country was under the curse of the system of cramming a number of subjects into the heads of the poor students.

Mr. MARSHALL seconded the motion.

Dr. STRUTHERS objected to increasing the burden of Latin by adding passages from unspecified authors. He did not believe in Latin as the best subject for mental training. He had had large doses of Latin and Greek in his younger days, and had done his best to forget them, in which he had succeeded pretty well, except in regard to nomenclature. A minimum of Latin should alone be required, including a little translation and a little grammar.

Dr. PETTIGREW agreed with the remarks of Dr. Struthers, and hoped that the Latin examination would remain unaltered. A student might be much better employed than in studying ancient languages, which were inferior in utility to modern languages.

Mr. SIMON supported the motion, and said that the line had hitherto been drawn ludicrously low in regard to Latin, so that it could hardly be called a Latin examination at all. Now that two subjects had been withdrawn, he thought that some of the remaining subjects might be strengthened.

Dr. HERON WATSON supported the motion.

Mr. MACNAMARA said that as the curriculum had been lightened, it was only right that something should be done to render the examination in the remaining subjects more effective.

The motion was put and carried.

Dr. LYONS moved that Greek be inserted in the programme.

Dr. BANKS, in seconding the motion, said he was astonished at the remarks of Dr. Struthers, who, although coming from Scotland, had said that he would be satisfied with a minimum education in the dead languages. It was a strange way of raising the preliminary education to exclude Greek from the list of subjects of examination. He feared that it would be introducing the thin edge of the wedge.

Dr. HAUGHTON was satisfied to allow Greek to remain an optional subject, but strongly opposed its entire exclusion. The compromise formerly effected on the subject was, he believed, a wise one.

Dr. STORRAR, while highly appreciating Greek, and desiring it to be a necessary part of the training of a medical student, said it was impossible to secure that object, seeing that so many boys were not taught Greek at school. All that could be done was to retain it as an optional subject.

Dr. A. SMITH opposed the motion, which he contended was an impracticable one.

The motion was put and rejected.

Dr. HUMPHRY moved: "That instead of two books of Euclid, geometry comprise the first book of Euclid, with easy questions on the subject matter of the same."

Dr. HAUGHTON seconded the motion, which was carried without opposition.

Dr. HUMPHRY moved his next proposed modification—viz., "Elementary mechanics, to be passed before registration." He said it might not be possible to include the subject in one preliminary examination, but it might be passed separately before registration as a medical student.

Mr. MACNAMARA said that the proposal was a vital one for the Royal College of Surgeons of Ireland, where a preliminary examination was passed not including mechanics. If the proposed alteration were made the student would have to go through one year of professional study for which he would get no credit, as he could not be registered as a medical student.

Mr. MARSHALL thought the difficulty would be got over by allowing the student to pass the examinations at two different periods.

Dr. HAUGHTON said that Trinity College, Dublin, could not alter its regulations to suit the interests of one profession. The public entrance examination to that College did not include mechanics, but the subject was well taught in the Arts course. Their entrance examination was not intended for the medical profession alone, but for every profession. If the alteration were made the students who passed the entrance examination could not be registered as medical students. Indeed, only a degree in Arts would qualify the candidate for registration.

Mr. SIMON thought that the case of Trinity College, Dublin, could be provided for by a special clause.

Dr. STRUTHERS said that the examinations at the universities should be made to bend to the rules of the Council. Students might, he thought, take mechanics in the first instance, by a three months' course, before entering upon the other subjects. The subject was of great importance to the young medical student.

The motion was put and agreed to.

Sir H. PITMAN moved the following "foot-note" in substitution of the existing one: "This subject may be passed apart from other subjects at an examination conducted by any one of the recognised examining bodies."

Mr. E. MARSHALL seconded the motion.

Sir H. PITMAN, in reply to Mr. Macnamara, said that the object sought was that every candidate before being registered as a student should pass in all the subjects of preliminary education, but not necessarily at one and the same examination. At present there were many who did not pass in mechanics at all. The option was given them to pass at a subsequent professional examination, but there was no guarantee that they ever did so. When a candidate presented his certificate of registration, it was assumed that he had complied with all the requirements of the Council. The examining bodies could not be expected to act as policemen to see that the regulations were carried out. At the College of Physicians the registration certificate was accepted as a sufficient indication that those regulations had been complied with.

Mr. MACNAMARA suggested that a special entry might be made, in a space left for the purpose, as to whether the candidate had passed an examination in physics.

The REGISTRAR said that that was done at the office.

Mr. MACNAMARA said it would be the fault of the bodies themselves if students were allowed to evade the examination. The regulations of the Royal College of Surgeons of Ireland had received the sanction of the Secretary of State, and it would necessarily come into collision with the Council under its new Recommendation.

The motion was put and carried.

Dr. HAUGHTON moved, and Mr. SIMON seconded, the following "note": "Such (university) candidate shall be entitled to registration if the regulations of their universities necessarily involve a higher training and examination in mechanics than the preliminary examination in mechanics contemplated by the General Medical Council."

Mr. MACNAMARA pointed out that a student of Trinity College might pass the entrance examination (which did not include mechanics), and then, after being registered as a medical student, might leave the College altogether, and go through a medical course without taking mechanics at all.

Dr. HERON WATSON said he believed the medical studies at Trinity College, Dublin, overlapped the preliminary studies; whereas the desire of the Council was that the student in his medical course should be untrammelled by preliminary subjects.

Sir H. PITMAN called attention to a resolution passed by the Council in 1881, when the subject was fully considered: "That the examiners in general education conducted by the universities be accepted as heretofore, but that if in any of these examinations the subjects of elementary mechanics, solids and fluids, are not included, a knowledge of those subjects should be required at a subsequent examination."

Dr. HAUGHTON thought it would perhaps be better to leave out the "foot-note" with regard to the universities altogether, leaving Trinity College, Dublin, to deal with the situation as it best could.

Dr. Haughton then withdrew his proposal; and the "foot-note" No. 1 was also withdrawn.

Dr. HUMPHRY moved: "That the optional subjects be omitted altogether." His object, he said, was not to cast a slur upon the subjects in question, but to carry out the principle of diminishing the number of subjects required.

Mr. MACNAMARA, in seconding the motion, said he had voted for raising the Latin examination with the hope that some of the optional subjects would be thrown over. A man might be examined in Greek if he liked; but as to the

Digitized by Google

other optional subjects, it was most desirable to lighten the ship of every one of them.

Dr. PETTIGREW was in favour of retaining the optional Council subjects, and thought the Council would err if it tied the student down to Latin.

Dr. BANKS spoke in favour of retaining the modern languages as optional subjects.

Dr. STRUTHERS thought that Greek must be recognised as one of the optional subjects. As to modern languages, the Council, in dealing with a profession which was essentially modern, ought not to refuse to encourage the study of French and German, and also Italian. He should not shed tears if logic were omitted; and elementary chemistry might with advantage share a like fate, because it was in all the professional examinations. He would, however, move that the subject of zoology be added to the list.

Dr. PYLE seconded the addition of zoology.

Mr. SIMON said he would gladly vote for Professor Humphry's resolution, which he considered an essential part of the reform which the Council was contemplating. The list of "optional subjects" represented to a great extent the crotchets or idiosyncrasies of individual members of the Council. Professor Struthers wished to add zoology, but why not add "things in general"? If the object were to give marks to any kind of knowledge—and it really came pretty nearly to that—why not say that a man who should pass an examination in Shakespeare or Milton should gain something? The purpose of the Council was that no man should be admitted to begin his medical studies without certain definite knowledge, and not to put after that requirement *plus* half a score of other accomplishments, many of which had been got more or less by chance.

Mr. MARSHALL dissented from the idea that the optional subjects represented the crotchets of the Council. He should like to see the profession joined by men of varied abilities; and if a candidate were an able French scholar he ought to be given due credit for it.

Dr. HAUGHTON thought it would be impossible for the Council, without committing a breach of faith, to remove Greek from the list, but elementary chemistry and logic might be excluded.

The motion for the omission of the optional subjects was then negatived, fourteen voting against it and seven in its support. The motion of Dr. Struthers, that zoology should be included in the list, was then put to the Council and agreed to.

Mr. MACNAMARA moved the omission of logic, but after a short discussion the motion was withdrawn.

The Council then adjourned.

THURSDAY, OCT. 16TH.

At the sitting of the Council in committee to-day, a resolution proposed by Dr. Struthers, "That the subjects of the preliminary examination for the registration of medical students be allowed to be passed at one or more examinations," was carried, after debate, by 10 votes to 8. The Council having resumed, considered and adopted the report brought up by the committee on the subject of preliminary education. It was also resolved that the amended regulations upon preliminary examinations should be communicated to those examining bodies whose examinations are recognised by the Council, but that they shall not come into effect until October 1st, 1885. Notices of motions by Dr. Haughton and Dr. Lyons were withdrawn, and on the motion of Dr. Lyons a committee was appointed to consider the question of a more suitable place of meeting for the Council.

This brought the business of the Council to a conclusion, and the session accordingly terminated.

THE WESTERN DISTRICT FEVER HOSPITAL.

FROM the annual report of the Medical Superintendent, Mr. R. D. R. Sweeting, we learn that during the year 1883 236 cases were admitted, 197 of these being scarlet fever, 18 enteric fever, and 13 typhus fever cases, the remaining 8 suffering from other diseases. The total number of deaths was 21, 15 of these being due to scarlet fever, 2 to intercurrent measles in scarlet fever cases, 3 to enteric fever, and 1 to inflammation of the kidney (tubal nephritis). The total mortality per cent., calculated by the Registrar-General's formula, was 7·92. That from scarlet fever was 6·77, and from enteric fever 14·63. Of the 8 cases admitted suffering from diseases other than scarlet, enteric, or typhus fever, 3 were cases of German measles, 2 of measles, 1 of tubal nephritis, 1 of diarrhœa, and 1 of gonorrhœal ovaritis; the cases of German measles, measles, and nephritis were sent in as being scarlet fever, those of diarrhœa and ovaritis as being enteric fever cases. Six cases of scarlet fever, also, developed eruptions of German measles in their course, the infection being started either directly from one of the cases admitted with the disease, or being due to the concurrent infection of one or more outside. Two cases, also, of chicken-pox coexisting with scarlet fever were noticed, in one of which the eruption of the former was just showing, in the other it was in a more advanced stage. These cases infected a scarlet fever convalescent. Five of the nursing staff and one kitchenmaid were attacked with scarlet fever, but none died; all were first attacks. An assistant nurse contracted typhus fever and died. Two others caught measles and enteric fever respectively, and recovered. Seventy-eight visitors paid altogether 258 visits to patients. None of the visitors were subsequently admitted with fever. Eight tables of statistics are appended to the report, which show that 83 per cent. of the admissions were scarlet fever cases, and 71 per cent. of the deaths were from that disease. September was the most active month in the point of admissions, which came to 41; of these 40 were scarlet fever cases. The mean total quarterly admissions were 59, and this was exceeded both in the third quarter (72) and the fourth (62). Kensington contributed 44 per cent. of the total admissions, Fulham 30 per cent. Of the total admissions of scarlet fever, 58 per cent. were under ten years. The mortality was greater amongst males, and heaviest in those under five years; the deaths from enteric fever were all male cases; no deaths from typhus fever occurred, 5 only as a matter of fact being treated, the others being transferred. Table 8 comprises (1) a list of complications and sequelæ observed in completed cases of scarlet fever; (2) a list of complications and sequelæ observed in completed cases of enteric fever. Amongst the kidney affections noted as complications and sequelæ of scarlet fever, acute desquamative nephritis and simple albuminuria hold equal positions, being equal to a percentage of about 12 on the total of completed cases; ascites was only present in one case. The cervical glands were enlarged in 105 cases; purulent otorrhœa was present in 33, and purulent nasal catarrh in 17. Uræmic convulsions were noted in 8 cases, and a true relapse in 10. Acute rheumatism figured as a complication four times, and there were three cases of retro-pharyngeal abscess.

DESTRUCTION OF THE CHRISTIANSBORG PALACE: ADDRESS TO THE KING OF DENMARK.

THE following is the text of an address presented to the King of Denmark by the English, Scotch, and Irish members of the International Medical Congress which met in Copenhagen last August. The destruction by fire of the beautiful palace, where the members of the Congress were so royally entertained, awakened general sympathy, which finds fitting expression in the terms of the address. The exact number of signatures appended to the address is sixty-three, every endeavour having been made to secure the signature of those who were actually present. The signatures were obtained by letter, and copied in facsimile on the vellum containing the address.

To His Majesty Christian IX., King of Denmark.

May it please your Majesty,—We, the undersigned English, Scottish, and Irish Members of the International Medical Congress lately held in Copenhagen, desire, very respectfully, to offer to your Majesty the expression of our profound regret at the destruction of the grand and beautiful Palace of Christiansborg. We very gratefully remember the honour conferred on us in that palace, where we were received and entertained with splendid and graceful hospitality by your Majesty and the members of your Royal Family. The recollection of that reception and of all the proofs of welcome which were shown to us in the City of Copenhagen impels us to offer, and to hope that your Majesty will graciously accept, this assurance of our sorrow for the loss which your Majesty and Denmark have sustained.

THE LANCET.

LONDON: SATURDAY, OCTOBER 18, 1884.

THE greatest apologists of the Medical Council would scarcely deny that the Council never appeared to greater disadvantage than it has done during the present sitting. We gave some illustrations last week of the questions on which members thought fit to spend hours and days of the Council's time. Since we last wrote, one or two questions of a graver and more practical kind have engaged the attention of the Council. But, for the most part, the order of business has been bad, indications of the sense of proportion have been slight, most of the questions that have been discussed had better have been left alone, and on the one subject of importance that has come before the Council a gravely wrong conclusion has been reached.

Whenever the Council does not know what else to do, or how otherwise to occupy its time, it falls back upon the subject of Preliminary Education. This is a theme that never fails. Fully a day or two is occupied in determining the shape that the discussion shall take, and the subject is one on which no two educationists are agreed. The rival claims of Latin and Greek, of modern and ancient languages, of literature and physics, of botany and zoology, of geography and history, are the questions on which the Council can always spend the best part of a week. It would matter less if its Recommendations were acted on. But they are not. And the Council is constantly laying itself open to uncomplimentary intimations from the universities and other bodies that they cannot adapt their examinations to the constant and capricious changes of the Council's regulations. There seems some fatal defect of memory on this subject in the most reasonable members of the Council. One such member said in the course of the present discussion, in reply to Dr. STORRAR, who urged that this subject was too often tampered with, that it had not been discussed for seven years. Turning to the minutes of the Council, we find it was most exhaustively discussed no further back than July, 1880. No less than four or five days were spent then in revising the regulations in regard to preliminary examinations. Here in 1884—actually only two years after the regulations then agreed to have come into operation—the Council deliberately opens up the whole subject, spends about three days and nearly six hundred pounds in going over the very same arguments and proposals, and in arriving at almost the identical results that were reached in 1880. Can it be wondered at that the universities are contemptuous of the Council and its Recommendations, and that school teachers and students are kept in perpetual and perplexing uncertainty? The actual changes made as the result of all this labour are the omission of English history and modern geography from the list of compulsory subjects and the inclusion of zoology among optional ones. One of the most curious facts in regard to this indefensible waste of time over an exhausted subject was that its discussion was initiated by Professor HUMPHRY, who ought to have remembered the rebuke administered by the chairman of the Board of Medical Studies of his university and the vice-chancellor of the University of Oxford to the Medical Council for not leaving such subjects, in accordance with its own expressed views, to the National Educational Bodies.

There are two subjects on which the Council will perhaps stake its reputation, and think that it has given a respectable judgment. The one of these was a motion by Dr. HUMPHRY, carried by all but three of the Council, "That no person shall be granted a degree, diploma, or licence to practise, registrable under the Medical Act, unless he has proved his competency in medicine, surgery, and midwifery, by passing examinations, in those subjects at one or more of the licensing bodies." The Council must really be very easily thrown into a state of self-complacency if it can be proud of itself for passing a resolution of this kind. *Cui bono?* Nearly every existing body does already examine in all the three branches of medicine. Probably only the Apothecaries' Societies do not. But even so, with one exception, their diplomas are not diplomas in medicine, surgery, and midwifery, but in one or other only of these branches. However complete the examination, in the existing state of the law the diploma is one-sided, and the student compelled to take two.

Another act of the Council, which many of its members seem to regard as a great feat, was the sanction of the conjoint scheme of the London Colleges, leaving out the Apothecaries' Company, on which we have already expressed an unfavourable opinion, and on which we shall next week have to say much more. The Scotch members to a man supported this resolution, but no less than ten members of the Council did not vote on the question. The vote, indeed, at the last was taken in a somewhat stormy Council, most of the members objecting to closing the discussion, desiring either to spend more time over the motion or to compel the co-operating Colleges to take in the Apothecaries' Society, which is left out in the cold to do an independent business, and which indeed has a good chance of doing a good business, giving a diploma which will cost but six guineas and will entitle men to registration and qualify them for five-sixths of the work of medical practice. It is intelligible enough that the Scotch members should unanimously have sanctioned a scheme which seems so well calculated to drive men for degrees and diplomas to Scotland. But how a General Medical Council could be found to sanction a scheme so unjust, so extortionate, and so impolitic we are at a loss to understand. We do not believe that even the Medical Council and the corporations can always resist the effects of such bad work as they have been doing of late. For the time being, with a demoralised and incompetent Legislature, such things may go on. But the day of reckoning will come.

THE Army Circular of October 1st contains a Royal Warrant, based on the report of Lord MORLEY'S Committee, amalgamating the Medical Department and the Army Hospital Corps. The Medical Officers and Quartermasters are in future to be designated "the Medical Staff"; and the Warrant Officers, Non-commissioned Officers, and men of the Army Hospital Corps, "the Medical Staff Corps." Besides this change of title, the Warrant makes a very

Digitized by Google

important addition to that of June 10th in the following two clauses: (1) "The officers of the Medical Staff shall be the officers of, and shall command, the Medical Staff Corps, as well as all patients in military hospitals, and such officers, non-commissioned officers, and men as may be attached for duty to the Medical Staff Corps; but they shall not hold any military command outside the corps." (2) "An officer of the Medical Staff, selected by the Director-General and approved by our Commander-in-Chief, shall be appointed staff officer of the Medical Staff Corps." The Warrant gives medical officers the power, "when non-commissioned officers or men are guilty of misconduct, or show themselves negligent or indifferent while in the performance of departmental duty," to stop the whole or a portion of their departmental pay for the day. They have also the power to reduce first or second class orderlies to a lower rank, subject to the confirmation of the principal medical officer of the district or command. It must be very satisfactory to the army medical officers to have their position with reference to the men employed in hospital duties thus clearly defined, and the control of the establishments for which they are responsible entrusted to them, subject only to the administrative officers of their own service and the generals commanding districts at home or commands abroad.

Simultaneously with the promulgation of this Warrant, a General Order has been issued from the Horse Guards directing the establishment, in connexion with a general hospital at the base of operations in time of war, of a depôt, under the command of an experienced officer, for the reception and accommodation of men when discharged from the hospital. The duties of this officer will include the charge of the arms, equipment, &c., of the men, the settlement of their accounts, the issue of routes, the conduct of all correspondence not of a professional character, the interment of the dead and the disposal of their effects, and the report to their corps of the arrival and departure of sick and invalids and of deaths occurring in the hospital. "The depôt will be considered a necessary part of general hospital organisation, and will accompany a hospital on active service when and where it may be moved or established." It is distinctly laid down in the Order that the officer commanding the depôt "will have no authority over the hospital or its staff, and is not to interfere in any way with the discipline, order, or arrangement of the hospital, or its staff, or inmates, the whole of whom are subject only to the orders and control of the principal medical officer, under the general officer commanding at the base or in the district in which the hospital is established."

YEAR by year the importance of the duties performed by the Port Sanitary Authority of London, especially in so far as these relate to the protection of the health and sanitary interests of the metropolis, increase in importance, and the report which has just been issued by that authority and their medical officer of health, Dr. COLLINGRIDGE, for the first six months of the present year, deals with matters deserving considerable prominence. The limits of the port district have now been definitely defined, and the jurisdiction of the authority extends to Port Victoria, Sheerness, Queenborough, and to a portion of the Medway, in addition to the Thames and its banks as far as the Nore. The sanitary control of such a district, if efficiently carried out, must constitute one of the principal safeguards to the metropolis and to the country generally, with regard to the importation of infectious diseases and other matters, and it is evident that the existing administration leaves but little to be desired in point of efficiency. The river and its shipping are subject to constant inspection, a special steam launch is maintained to aid in this work, a deputy medical officer of health is available for the Gravesend portion of the river, an excellent infectious hospital has been erected in a suitable position on the banks of the stream, arrangements are in force for obtaining the earliest possible information as to the existence of infectious disease, means for the disinfection of clothing and other articles are available, and the whole system of work is under efficient supervision. The existence of cholera at Toulon and Marseilles, and later on at Naples and Genoa, would in years gone by have been a source of great alarm in connexion with the shipping coming from the Mediterranean ports to London; but this year, although the occurrence has necessitated much increase of vigilance and of work on the part of the port officers, yet the state of preparedness which had been attained enabled them to face the danger with a degree of confidence which has never yet before been possible, and the country itself, knowing all that has been done, cannot but share in the trust which may be placed in the organisation now established. Had it been necessary, the staff for inspection purposes would have been materially increased, the means of isolation were already available, and the system of protection against cholera importation on which we rely in this country would have been fully carried out. As it was, rigid inspection was made of ships and, where necessary, of crews and passengers, the utmost cleanliness as to water bilges, and all matters affecting the sailor was insisted on, and a notice was freely distributed as to the need for cleanliness and the early treatment of diarrhœa. A system of notification of infectious diseases has also been brought into operation. From the commencement of this year it became necessary that every master or person in charge of a vessel should report the existence of any case of certain specified infectious diseases not more than two hours after reaching either Gravesend or Greenwich, and since the issue of the necessary notices, wilful concealment of disease which was formerly practised has come to an end. Were any such organisation and appliances in actual working in foreign ports, the days for rigid quarantine measures would probably be nearing their end. But the work of the port officers is in no way limited to the protection of the country against infection. Our food supplies are subjected to a rigid inspection when arriving through the port of London, and owing to the imperfections still attaching to the methods for freezing meat and canning articles of food, it has been found necessary, after careful examination, to condemn large quantities of such articles. The labour involved in this is very great; it generally necessitates the examination of the whole consignment, and when unsound articles such as meat are discovered they are disinfected before removal so as to avoid nuisance, and then they are destroyed at certain depôts under the supervision of one of the port inspectors, the owner or consignee paying all expenses. The polluted condition of the Thames has also been a matter of continued concern to the authority, whose labours in the

Digitized by Google

interest of maintaining our great watercourse in a reasonably wholesome state deserve the recognition of the whole public. During the past half year the state of the river has been worse than ever, and its fetid filthiness, previously somewhat obscured under the cold summers we have experienced, has been revealed in all its loathsome nakedness. The area of pollution seems also to be increasing as the metropolis becomes more populous, and Dr. COLLINGRIDGE reports that the whole river from Purfleet to Limehouse is of a dark colour, with blacker patches here and there, and has a most disgusting smell. The action of the Metropolitan Board of Works, in so far as they affect to deodorise the vast mass of sewage, is condemned as unsatisfactory, and it is difficult to conceive that it could be otherwise regarded.

DR. CRICHTON BROWNE is mercilessly vivisecting Mr. FITCH, so far as that gentleman may be embodied in his memorandum. In a series of lengthy but singularly lucid and, if we may say so, amusing letters in *The Times* the author of the report is administering a "policy of reprisals," of which the author of the memorandum forms the victim. We do not envy Mr. FITCH or his chief. They did not form an adequate estimate of the "knee-jerk" in Dr. CRICHTON BROWNE when they tried to sclerose him in the proliferating fashion of the great educational department presided over by Mr. MUNDELLA. Entirely in consequence of the tests applied it has come out reflexly that Dr. CRICHTON BROWNE was not a volunteer inquirer, as alleged for parliamentary purposes; that he did not take the first step in the matter, but was actually "sent for" and "asked" to investigate the subject of "over-pressure"; that Mr. FITCH was not less ill-informed than ill-mannered when he affirmed that Dr. CRICHTON BROWNE was unqualified by experience for the task he had undertaken. Nothing can be more destructive than Dr. CRICHTON BROWNE'S scathing though courteous rejoinder to Mr. FITCH; and the question at issue may now be lifted out of the region of departmental and personal strife, and placed on the basis of ascertained fact. There *is* over-pressure in elementary schools, let who will or may deny the fact and affirm its contradiction.

Moreover, the pressure proved to exist is very great and mischief-working. The undeveloped brains of half-starved children, in whom heredity, adverse surroundings, and too often actual disease combine to handicap energy, are strained and irritated by the application of a code framed in ignorance of the first principles of brain-life and function, and administered in an offhand and indiscriminate fashion. The results are damage and wreckage; and for every case that is brought under public observation there are many that pass unnoticed. Mr. MUNDELLA and his subordinate may deny or question these facts as they please. It is an all-sufficient answer that they *are* facts, and no amount of ingenuity can ignore them. The time has come to speak plainly on this subject. The moment Mr. FITCH was commissioned to annotate Dr. CRICHTON BROWNE'S report—a non-medical man to criticise and contradict the expressed opinion of a physician who is almost a specialist on the physiological aspects of the educational question—the Education Department of the Privy Council placed itself wholly and irretrievably in the wrong. It was only necessary to wait until the author of the report had published his rejoinder before taking up a formal position in the controversy. Dr. CRICHTON BROWNE has now disposed of the personal question, and we are free to speak.

In the name of common sense we ask, What does the Vice-President mean by such trifling with a grave question as that in which he has indulged with the aid of his inspector? When Mr. MUNDELLA sent for Dr. CRICHTON BROWNE, he must have had one or the other of two purposes in his mind, either to make evidence to bolster up his department, or to obtain an honest opinion on its administration. If Mr. MUNDELLA claims to have sought only a good professional judgment, why does he complain because it is against him; and, above all, why does he charge or allow a non-medical inspector to assail and insult the very physician selected by the Vice-President for the investigation?

When first we commented on this topic, we likened Mr. MUNDELLA'S commission to Mr. FITCH to that of the defendant who, having no case, instructed his counsel to abuse the plaintiff's attorney. The matter turns out to be one of far greater gravity than this comparison would serve to indicate. Mr. MUNDELLA has allowed his attorney to abuse the Judge—the Judge, be it observed, of his own selection, and to whom he deliberately appealed. This being so, we have no words strong enough to mark our sense of the insult Mr. MUNDELLA has by his agent offered to the medical profession, as represented by Dr. CRICHTON BROWNE. The strait in which the Department found itself cannot for one moment be accepted as an excuse for the offence committed. The facts have proved to be against the policy pursued, and a deliberate attempt has been made to deny or misconstrue them. It only remains to say that the allegations of Dr. CRICHTON BROWNE'S report are abundantly supported by independent evidence; and now that the bad faith of the Department stands confessed, the appeal must lie to the common sense of the community. It is intolerable that the policy of over-pressure should be pursued, and, with Dr. CRICHTON BROWNE, we say it must cease.

Annotations.

"Ne quid nimis."

HOSPITAL SUNDAY FUND.

THE Council of the Hospital Sunday Fund met on the 10th inst., to discharge a pleasant duty—viz., to dispose of £4500 which had been sent by His Royal Highness the Prince of Wales as the result of the recent hospital fête. In addition to this sum, £713, which had been paid into the fund since the last meeting, had to be distributed. The Council determined wisely to divide the money *pro rata* among the various hospitals and dispensaries which had recently received the bulk of the fund. One interesting feature of this incident is the proof which it affords of the confidence of the Prince and the public, which he so well represents, in the judgment of the Council of the Hospital Sunday Fund. This sum had of course no connexion with Sunday or any religious denomination, but yet was forwarded for distribution to the Hospital Sunday Fund. Dr. Glover argued that such proofs of public confidence made it incumbent on the Fund to consider whether in any other or further way they could promote the public support of hospitals. Referring to the recent discussion in *The Times*, in which

Digitized by Google

Mr. Burdett ably shows that the income *from all sources* of all the hospitals has not fallen off since the institution of Hospital Sunday, but has, on the contrary, increased by 8·9 per cent., Dr. Glover maintained that hospitals had not suffered from, but had benefited by, the Fund, and that the treasurers of hospitals would be very sorry indeed to be deprived of the assistance of the Fund, and urged that the authorities of individual hospitals should increase their energy and inventiveness in devising new sources of support. His resolution, unanimously agreed to, was as follows: "That it be an instruction to the General Purposes Committee and the Distribution Committee to consider whether any, and what, means could be recommended for adoption by the Council for increasing the power of the Hospital Sunday Fund in its efforts to develop and extend the public support of the medical charities of the metropolis." Sir Sidney Waterlow expressed very powerfully an obvious objection to giving a "district" or localised character to the Sunday collection. This would debar the inhabitants of the rich districts from the pleasure of helping hospitals in poor districts, and it would tend to belittle and parochialise a great metropolitan movement. But this and all other suggestions, we may be sure, will be fully considered by the committees to which the instruction expressed in Dr. Glover's resolution has been referred.

PRECAUTIONS AGAINST CHOLERA.

THE War Office has just issued, in the October *Army Circular*, a new code of instructions to commanding, medical, and other officers of the army for "guidance at a time when there is reason to anticipate an outbreak of cholera, or when it is actually prevalent among the troops." They are divided into three sections, the first being the precautions to be adopted in anticipation of an epidemic; the second, additional measures when it has broken out among the troops or the surrounding population; and the third, the instructions respecting disinfection. The measures to be adopted when an epidemic of cholera is expected may be summarised as follows: great attention to the sanitary condition of barracks and camps, and the removal of nuisances in the neighbourhood; avoidance of crowding in barracks; attention to ventilation, cleaning and lime-washing of walls and ceilings, regular emptying of ashpits and cesspits, and flushing of latrines, sinks, and drains; examination of traps, ventilating shafts, and valves connected with sewers and drains; particular attention to the water-supply, and inspection of the rations and other supplies for the use of the troops. The night duties of the soldiers are to be reduced as much as possible, and arrangements made for speedily changing wet articles of clothing. A small body of men are to be exclusively employed in carrying out conservancy duties in barracks. The additional measures when cholera has broken out among the civil population are the prevention, as far as possible, of soldiers going into affected districts, the camping out of a portion of the troops if the barracks are overcrowded, the issue of tea or coffee to the men before going on early morning or night duties, the issue of two flannel belts to each soldier and the use of flannel shirts, and a careful watch for men suffering from looseness of the bowels. When a case occurs in barracks, the room is to be vacated, fumigated, and cleaned, and if the disease spreads, the troops are, on the advice of the principal medical officer, to be camped out when practicable, and the site of the camp changed if necessary. The evacuations of the cholera patients are to be "passed into vessels supplied with chloride of lime, cupralum, or carbolic acid powder, and thereafter buried in some place or disposed of in a drain set apart for the purpose." Under the third head—"Disinfecting Agents"—chloride of lime or quicklime is to be used when a considerable space and bulk of material are to be dealt with; cupralum is especially applicable for bed-pans, closets, &c., and carbolic acid powder for urinals, privies, dust-heaps, &c., as well as for bed-pans, and closets. For the purposes of fumigation, chlorine gas, nitrous acid gas, or sulphurous acid gas may be used, and detailed instructions are given as to the quantities required for the disinfection of 1000 cubic feet of space, and the mode in which these gases are to be prepared and employed. The instructions appear to us to have been carefully drawn up, to be very practical, and to be likely to prove useful in preventing the spread of the disease should it unfortunately break out among our troops or the civil population.

MEDICAL EDUCATION IN AMERICA.

THE current number of *Le Progrès Médical* contains a letter—the first of a series—from M. L. Thaon, giving an account of medical education in the United States. He has visited several of the leading schools on the route from San Francisco to New York, and his description will be read with interest. He points out that, unlike France and Germany, but like England, medical education in the States receives no support from Government, which is so prolific in its favours to primary education. The American is, he believes, the outcome of the English system, which "leaves medical instruction in the hands of a dozen free and independent corporations, who teach and confer diplomas without any Government interference"; but he points to the projected Medical Act as an indication of the desire on the part of the English profession to adopt the continental plan. There are "three medical schools in New York, besides the Women's College; two in Philadelphia, and one for women; two in Boston; three in San Francisco; one in Denver—a town which did not exist twenty-four years ago; and there is one in another small town in Colorado of only 6000 inhabitants." In addition to the regular schools there are the *irregular*—viz., homœopathic, eclectic, and physio-medical, which last defies definition. Altogether there are 139 medical schools in the United States and Canada, containing about 12,000 students—viz., 10,000 regular, 1200 homœopathic, 750 eclectic, and 50 physio-medical students. The total number of doctors is about 100,000, or on an average one to every 500 inhabitants. M. Thaon goes on to describe how easily such schools are founded, and how they are maintained occasionally by public liberality, of which the Johns Hopkins University and the recent gift of 250,000 francs of Mr. Andrew Carnegie to the Bellevue College of New York, to provide histological and pathological laboratories, are striking instances. The maintenance of most of the schools depends on the students' fees; and an institution with fewer than 400 or 500 students can only be maintained at a sacrifice, or with inadequate remuneration of its teachers.

INSURANCE OF INFANT LIVES.

MUCH attention has recently been drawn to the evil effects which result from the insurance of the lives of infants. In Burnley, according to a report by Dr. Airy of the Local Government Board, the deaths of infants under one year of age is excessively high, the average rate being 20 per cent. of the births registered. This result is in part due to the practice of mothers employed in mills leaving their infants with old women who profess to look after them. But, adds Dr. Airy, it is strongly suspected that the very general practice among the poor in Burnley of insuring the lives of infants results in many cases in the death, on which it puts a premium. This is what numerous medical officers of health have long maintained, and it is to be hoped that some statutory restriction will soon be put upon a practice which is reprehensible in the extreme, and to which it is to be feared that many infant lives in this country have been sacrificed.

ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

WE believe that the sub-committee which was appointed shortly before the long vacation to prepare a scheme of reform has completed its labours, and that its report will be presented to the committee of the Association next Thursday. When the scheme has received the approval of the committee, it is contemplated to circulate a draft of it among the Fellows and Members of the College in order to secure the interest and co-operation of the whole of the members of the corporation. The details of the plan of reform have not yet transpired, but we are assured that when they are made known they will be found to aim at increasing the political and academic importance of the Fellows and Members, at the same time that they will add to the usefulness, influence, and dignity of the College.

INFLUENCE OF LIGHT ON THE DISSOCIATION OF OXYGEN BY PLANTS.

A CHEMICAL study, which may be mathematically investigated, is the question of the influence of light in disengaging oxygen from plants. The subject is one which has frequently received attention, but by no one more thoroughly than by Prof. Reinke. The method adopted by this observer was to calculate the number of bubbles of oxygen liberated by a given surface of a leaf, under the influence of varying intensity of light. The intensity of the light was obtained so as to be capable of exact measurement by means of a convex lens which transmitted light into a darkened chamber from a heliostat, which reflected the light of the sun. The intensity of light to which the leaf is subjected then varies according to its position in the double cone of rays formed by the lens. Working in this way, the author finds that the separation of oxygen obtains its maximum with light of normal intensity (i.e., at twice the focal distance of the lens, where the diameter of the cone of rays is the same as at the lens), that it rapidly diminishes with intensities of one-fourth, one-eighth, and one-sixteenth; but, on the other hand, remains almost constant when the intensity is two, four, and eight times the normal. The study of the influence of light of different colours on the disengagement of oxygen by plants has been investigated in a similar manner. The maximum disengagement of oxygen corresponds with the maximum absorption of the green colouring matter of plants, and is situated in the red, not far from the line B; the curve representing the degree of separation of oxygen descends rapidly towards the ultra red, more slowly towards the ultra violet; but, contrary to the experiments of Engelmann, there is no augmentation in the dissociation of oxygen corresponding with the absorption band, commencing between the lines *b* and F, and extending over the whole of the right side of the spectrum.

THE WIDTH OF STREETS.

MUCH advance has been made during recent years in securing increased space about inhabited dwellings, and modern regulations require that a certain minimum of space shall be given in the rear of houses, and also to the front, the width of the street being taken into account as regards the latter space. But in the State of Illinois the excessive width of the streets is reported as having of itself become a source of nuisance and of danger to health. Sixty feet and more are ordinarily given to new streets, even in the smaller towns; eight feet on either side are paved and devoted to pedestrians; and the remaining space, varying usually from forty-four to fifty-four feet, is devoted to carriage traffic. The result is that this wide carriage road, so often in excess of the requirements of the vehicles that have to travel over it, becomes a source of such expense as to forbid its being properly paved, cleansed, and channelled. The street consequently is soon turned into a vast surface of dirt mixed with filth, horse droppings, and other refuse, and when the weather is so dry that dust is formed, the air which is inhaled as the dust flies about is calculated to bring about disease as well as discomfort, instead of promoting the health of pedestrians. Dr. Gregory in bringing forward this subject fully concurs in the great importance of providing wide thoroughfares, and of keeping the number of inhabitants to each acre down to a proper maximum, and hence he declares that he would not on any consideration diminish by a single foot the width of the streets. But he would curtail the actual roadway, so that it shall only suffice for the proper demands of the carriage traffic, and between that limited space, which could then be properly kept at a reasonable cost, and the foot-paths, he would plant trees and lay down grass, so as really to provide in towns and cities such freshness and greenness as would go far to induce people to take that form of exercise which is most conducive to health. The hints given are as well worthy of attention in this country as on the other side of the Atlantic. Something has been done in this direction both in the metropolis and in other towns within the past few years, but there is still room for much that would help to render our town thoroughfares both more healthful and more attractive.

MIGRAINE AND TABES.

AMONGST the various prodromata of tabes dorsalis, attention was drawn by Duchenne, and later by Pierret, to the occurrence of neuralgic seizures closely simulating hemicrania; and the recent brochure of Berger, to which we have previously referred, mentioned this fact as a novel observation. Dr. H. Oppenheim of La Charité, Berlin, points out (*Berl. Klin. Wochenschr.*, 1884, No. 38) the priority of the French authors, and supplies some interesting details of twelve cases, from a total of eighty-five tabetics, who either were at the time of observation or had previously been subject to migraine, ten of the patients being females. The study of these cases leads him to conclude that hemicrania is far too frequent a feature in the history of tabes dorsalis to be considered an accidental event, and that it is far more common among tabetic women—e.g., ten times in thirty-two cases—than among men. The relations which the hemicrania bears to tabes are various. Generally it has been present many years before the initial symptoms of tabes; and the hemicranial attacks increase in frequency, intensity, and duration as the disease advances. Or the migraine may coincide with the onset of declared tabetic symptoms, or be associated with vomiting and gastric crises. In rare cases the hemicrania does not appear until tabes is developed. On these grounds, Oppenheim thinks it the duty of the physician, especially in migraine of increasing severity, to be on the alert for the recognised early symptoms of tabes—especially the absence of knee-jerk.

MEDICAL REGISTRATION.

WE publish this week, in our advertisement columns, a notice by the Registrar of the Medical Council calling attention to the importance of every registered medical practitioner sending information to the branch registrar of the division of the kingdom in which he may be practising of any change in his address or of the acquirement of any additional qualification, in order that such change or addition may be included in the forthcoming Medical Register; also of replying at once to any letter of inquiry that may have been sent in regard thereto. Carelessness in the above matter has frequently been followed by great trouble and inconvenience.

HÆMOGLOBINURIA.

A PAPER on the above subject was read by M. Henrot at the recent meeting of the French Association for the Advancement of Science, and gave rise to an interesting discussion. (*Progrès Médical*, Oct. 4th.) Two cases were recorded in the paper. The first was that of a man aged thirty-two, with phthisical consolidation at one apex; he was also syphilitic. Occasionally, and as a rule after exposure to cold or muscular fatigue, he passed coffee-coloured urine. Before the attack, which was always pyrexial, the urine was clear and free from albumen; after the attack it contained albumen, but no blood-corpuscles. At the end of two years the hæmoglobinuria disappeared, but the urine became albuminous, and the patient eventually died of tuberculosis. The second case was that of a man thirty-five years of age, who had had four attacks, during which he passed characteristic urine containing albumen after the attack; urobilin was found in this urine. M. Henrot suggested that the dissolution of the blood-corpuscles in these cases was due to the presence in the blood of biliary acids. As to the treatment of hæmoglobinuria, he raised the question whether inhalations of oxygen might not be of use by increasing the resisting power of the corpuscles. In the cachectic period transfusion of blood might be resorted to. In reply to M. Maurel, he said that neither of the patients had shown any malarial symptoms; one had lived in Africa for some time. M. Hayem thought the rarity of icterus associated with hæmoglobinuria a forcible objection to M. Henrot's view. Another objection lay in the fact that for hæmoglobin to escape there should be a large quantity of it in the serum. In some experiments he made on this subject, he attempted to set the hæmoglobin free by injecting water into the blood, and found that it was not until a quantity of water equivalent to one-half the mass of blood in the animal was so injected that hæmoglobinuria (and then only transitorily) occurred. Yet the serum of the blood in cases of hæmoglobinuria is barely more coloured than normal, and the plasma contains about as much hæmoglobin as in health. Therefore, M. Hayem thinks, there is every probability that in this affection the hæmoglobin is altered, acting as if it were introduced from another species of animal, an experiment which immediately excites hæmoglobinuria.

ADJOURNED INQUESTS.

DR. DIPLOCK, coroner for West Middlesex, held an inquest at the Vestry Hall, Church-end, Willesden, touching the death of the Rev. William Spencer Edwards, who died suddenly at the residence of Dr. Keele, Cricklewood, Willesden. The evidence went to show that the deceased's health was greatly shattered, and that he suffered from great nervous prostration with excitement, which rendered advisable his removal from town to a quiet country place. The post-mortem examination was made by the divisional surgeon of police, who concluded that the fatal issue was from syncope consequent on cardiac disease. The jury, influenced, no doubt, by the facts disclosed during the hearing, considered themselves not justified in returning a verdict without further medical evidence. We do not wish to intervene between the jury and their verdict by discussing the merits of the case, but we cannot help thinking that when a dispute is likely to arise at the hearing it is well either that the coroner should appoint some medical expert approved by all the parties, or that each one should send its representative to witness the autopsy. In this way an adjourned inquest would in many cases be unnecessary, expense to the ratepayer would be saved, and what is of far higher importance, there would be less chance of the evidence as to the cause of death being destroyed by exposure and putrefaction of the body. We wish it clearly to be understood that we do not cast the slightest aspersion on the gentleman who conducted the post-mortem examination in this particular case, as we have no reason to doubt his probity and skill, but the event thus far shows the reasonableness of our suggestion.

VEGETARIANISM.

DR. B. W. RICHARDSON'S address, delivered at the dinner recently given by the Vegetarian Society at the Health Exhibition, was calculated in some measure to raise the hopes of those who look upon the flesh-pots as an abomination, and the consumers of animal food as guilty of depraved habits. Yet, although the speaker inveighed against the prevailing custom of a too exclusive indulgence in the carnivorous instinct, he discounted much that might have been taken as an advocacy of strict vegetarianism. There were, he said, vast social and commercial problems involved in the question that was now moving a section of the community to effect what they believed to be a reform in our national dietary. We have only to consider for a moment the utter confusion in the order of nature that would ensue on our refusing to resort to the animal world for a part of our sustenance. We are not of those who hold that the length of the intestinal canal is proof that man was never intended to regale himself with the luscious bivalve, or with well-seasoned game. Science teaches that structure and function are very closely connected, and a study of the doctrine of evolution reveals the fact that the anatomy of individual organs is largely dependent upon the work those organs have to perform. John Hunter showed this to be the case by the experimental feeding to which he submitted his tame gull. That the resources of the vegetable world are not drawn upon to anything like the extent that they should be we freely admit. Moreover, there can be little doubt that partial abstinence from, or in other words moderate ingestion of, animal food checks the craving for alcoholic stimulants, and thus proves itself a very desirable condition of life. But to declaim against the abuse of a particular viand is quite consistent with admitting its use. The members of the Vegetarian Society are to be congratulated upon the good they have already done and are still doing, but they must not be disappointed if they find that their arguments do not carry conviction to the minds of all those whom they address, or at any rate to the full extent of their desires.

THE METROPOLITAN ASYLUMS BOARD.

AT an ordinary meeting of the managers of the Metropolitan Asylums District on the 11th inst., the General Purposes Committee reported that one of the small-pox camps at Darenth had been disestablished and one of the hospital ships closed. The committee were of opinion that the time had now arrived when the several infectious hospitals under the control of the Board should be designated "fever hospitals," upon the understanding that at each of such hospitals isolation wards were to be set apart for the reception and treatment of small-pox or other patients, and the remainder of the hospital appropriated exclusively to the treatment of fever patients. The Board endorsed this opinion, and the hospitals will in future be described as fever hospitals. At the same meeting a letter was read from the Local Government Board authorising the managers to raise on loan an additional sum of £1630 for the adaptation of the *Castalia* as a floating hospital, and the finance committee was requested to prepare a return showing in detail the expenditure in the various asylums, hospitals, and camps during the year ended Michaelmas last, together with the daily number of patients and staff maintained, also the cost of maintaining them, the wards, steamers, and ambulance stations during the same period.

THE COSTLINESS OF THE MEDICAL COUNCIL.

IT is always well, in stating the weak points of individuals or bodies, to err in the way of understating rather than of exaggeration. It has been pointed out to us that, in our leading article last week, we have understated the costliness of the Medical Council. We had good authority for our estimate, but we have still higher for the following, which shows that the

Cost per day, on an average, is	£191	14	0
Cost per hour ,, ...	48	0	0
Cost per minute ,, ...	0	16	0

This estimate is taken from a paper of the Registrar, Mr. W. J. C. Miller, published in the Report of the Select Committee. It is calculated from the actual cost of three specified sessions. Thus—

(1) Session of thirteen days (1877) ...	£2204	4	11
(2) Session of three days (1870)	640	0	0
(3) Session of one day (on various occasions)	414	15	0

The cost (3) of one day's sitting includes not only fees for attendance, but travelling expenses, hotel expenses for members not residing in London, &c., which have to be paid, whether the session lasts one day or thirteen.

CARIES OF BASILAR APOPHYSIS.

THE diagnosis of the seat of a coarse lesion of the brain does not give any definite information of the pathological nature of the lesion. In actual practice rare pathological states can hardly be taken into account in considering the probable nature of any case of cerebral disease. M. Suzanne has given a careful account of a case of caries at the basilar apophysis which led to nervous symptoms as the result of compression of the pons Varolii by some inspissated pus, the product of the osseous ulceration. The main symptoms were paralysis of the left side of the face and of both arms and legs. Caries of the basilar apophysis is an unfrequent affection, which is generally attributed to syphilitic disease. The indications of syphilis in the case above referred to were by no means clear. The paralytic symptoms were probably due to combined compression and inflammation, the result of extension, of the pons.

DEVELOPMENT OF SPINAL NERVE CELLS.

AN interesting essay on the formation and development of the nerve cells of the spinal cord of mammals has recently been read by M. Vignal at the Académie des Sciences. The nerve cells begin to make their appearance in the spinal cord of the embryo of a sheep at the period corresponding to the tenth week of intra-uterine life of the human embryo; they are formed by a transformation of the cells which compose the embryonic grey matter. The nerve cells appear simultaneously in this substance in two principal groups; the first is situated at the inner part of the anterior horn, the second at the external margin of the anterior horn. The two groups correspond respectively, in the dorsal part of the cord, to the anterior group and to the lateral group; some other cells may be seen to be irregularly scattered through the anterior horn. At first the shape of the newly formed cells is irregular and variable; they possess long slender processes, which are sometimes bifurcated; their nucleus is large, has a clear well-defined outline, and contains one or two distinct nucleoli. All degrees of change may be met with between the embryonic cell and those just described. At the period corresponding to the fourth month of human fœtal life the cells in the anterior horns are much more numerous; the embryo of the sheep measures ·10 metre in length at this period. The cells of Clarke's vesicular column make their appearance when the embryo of the sheep is ·17 metre in length. A vague striation may be seen in the protoplasm of the cells at the age corresponding to the sixth month of human intra-uterine life; previous to this time the protoplasm has a homogeneous aspect. The striation appears to be due to the granules in the protoplasm having become finer, and arranged in a linear series. Corresponding to the seventh month the striation is more extensive, and becomes so pronounced that excessively fine fibrillæ may be said to exist. The fibrillation is universal in the cells of the anterior horn, and also in their ramifications at the period corresponding to the ninth month; the changes occur at a later period in the posterior horn. At birth the nerve-cells are practically finished in every respect except size, and they never contain pigment granules, which absence would seem to show that pigmentation is a product of degeneration.

ROYAL VICTORIA HOSPITAL, NETLEY.

CONSEQUENT upon the abolition of the appointment of a Military Commandant at Netley, the Horse Guards have issued an addition to the "Queen's Regulations and Orders for the Army" on the subject of the duties connected with the administration of the hospital. The first regulation laid down is that "the Principal Medical Officer, Netley, will be entirely responsible for the discipline and for the general management of the hospital." An Assistant Adjutant- and Quartermaster-General is to be stationed at Netley as representative of the General Commanding the district. His duty will be to report to the corps to which they belong, the arrival and departure of invalids, and all deaths occurring in the hospital, to see that all discharge documents are completed, and to forward them to the proper authorities, to settle all claims, to issue all routes, and to conduct all correspondence with corps not relating to medical subjects. He will be required to visit the hospital frequently, but at such hours as do not interfere with the medical officers, and to report to the General and to the Principal Medical Officer any irregularities he may observe and any complaints made to him which he may not have been able to adjust. "He will, however, never interfere in any way with the arrangements nor give any orders to the orderlies or others employed in the hospital." He is also to be responsible for the military police, for the discipline of all officers and men not patients in hospital or belonging to the Army Staff Corps or nursing establishment, for all military clothing the property of Government, and for the disposal of the effects of soldiers who die in hospital, which are to be handed over to him by the hospital authorities. These regulations appear to provide sufficiently for the military requirements in connexion with the invalids, while they leave the management of the hospital free from non-professional interference.

ALCOHOLIC DRINKS.

OUR contemporary *The Times* has done its best to make amends for the recent publication of an article in which the evils of drinking were extenuated and the uses of alcohol were drawn very large. It has allowed Dr. Alfred Carpenter to contradict it point by point by reporting his paper, delivered at a meeting of the Society for the Study and Cure of Inebriety. Cardinal Manning has been speaking on intemperance at Sheffield with the force which characterises all his public speeches. His address was interesting from a medical point of view, as containing quotations from the sayings of Sir Andrew Clark and Sir Henry Thompson on the immense harm done by drink. Sir Andrew had told the cardinal that in seven out of ten of his hospital patients disease was caused by drink, and in the three others was often aggravated by it. "At last," added Sir Andrew, "I have sometimes said to myself, Shall I not do more for the health of man if I give up the practice of

Digitized by Google

medicine and go about the country in a crusade to prevent the use of intoxicating drinks?" We trust Sir Andrew will stick to Cavendish-square, and from that pleasant vantage ground continue to "reason of temperance," like a favourite author of his, until a luxurious age begins to be convinced of its errors and to abandon its vices.

POLITICS AND SANITATION IN BELGIUM.

THE constitutional crisis which is disturbing the peace of Belgium gives special interest to the communal elections that are to take place throughout the country on the 19th of this month. Of course it is not our mission to interfere with the political points at issue; but, seeing how the whole national system of education has been disturbed and experienced teachers driven from their posts because they belonged to the opposition, we cannot but view the forthcoming elections with some anxiety. The municipal services in Belgium, but especially in Brussels, are admirably organised so far as the preservation of public health is concerned. In this Brussels is at least fifty years ahead of Paris; and, in some respects, in advance of the best organised towns in England. The *Service d'Hygiène* of Brussels, under the able directorship of Dr. E. Janssens, is a model institution, constantly visited by sanitary reformers from all parts of Europe, and serving as an example in all countries. The mortality tables, the system of disinfection, the methods of superintending, improving and controlling house drainage, the care of sickly children at primary schools, the organisation of the public vaccination office—in all these and many other services the most advanced methods have been employed and excellent results attained. Whatever, therefore, may be the issue of the present political struggle, we trust that the sanitary services will escape all disturbing influence.

YOUNG GIRLS IN LONDON.

SIR ANDREW LUSK spoke a few kind and sensible words in Islington on the 7th inst. in support of the Islington Young Women's Club and Institute. Sir Andrew said there were about 300,000 young women and girls in the warehouses and factories of the metropolis who had few comforts at home and few friends to advise them well and kindly. The young women of the metropolis with questionable taste are showing a tendency to prefer warehouse and factory work to domestic service. They have more liberty in such a career, but less of that discipline and duty of home life which is so good for human nature, especially in its female form. There is all the more need therefore of such institutes as that over which the worthy baronet presided.

THE TREATMENT OF TYPHOID FEVER.

AT the meeting of the German Scientific Association at Magdeburg a paper on the treatment of typhoid fever, based on an experience of seven and a half years—viz., from March, 1877, to September, 1884—was contributed by Professor Ebstein. The total number of cases was 235, and they were treated in the medical clinic at Holstein. The mortality was only 5·5 per cent., reduced to 2·5 per cent. by the exclusion of inevitably fatal cases. The author concludes that the so-called "abortive treatment" with calomel is useful and to be recommended. In the absence of any causal treatment, this can only be symptomatic—i.e., measures based on a consideration of the morbid phenomena and individual conditions. Above all, attention must be paid to judicious dietetic treatment and the maintenance of the nutrition of the patient. The control of high temperatures, even if of long duration, is only called for when they are associated with severe cardiac or nerve symptoms, or when the temperature attains such a height as to threaten life. The principles of treatment enunciated are, says Ebstein, far more satisfactory in practice and in their results than an exclusive adoption of "bath treatment" or other methods of strict antipyresis. Baths he regards as of value for their powerful stimulant action, and he would employ them where other methods seem to be insufficient.

THE HEALTH OF PROFESSOR HUXLEY.

MUCH regret will have been felt in many quarters at the announcement that Professor Huxley has been recommended to leave England for some months of perfect quiet and freedom from work. The position to which Professor Huxley has attained amongst scientific men is the result of severe and long-continued toil, taxing the powers of both mind and body to a very large extent. The preparation and delivery of lectures and addresses, the composition of memoirs to be read before learned societies, the writing of systematic treatises, the supervision of classes pursuing dissections, microscopic work, and physiological investigation, are duties that not only require a very active and versatile mind, but which cannot be discharged by any one man without a very severe strain on his powers of endurance. But Professor Huxley has done much more than this. As the champion of science and a strong advocate of its introduction into schools as a part of the mental discipline of the young, he has had a hard battle to fight with those who cling to ancient modes of thought, and who are unwilling to launch themselves into a surging sea of doubt and difficulty. For some years he was a member of the London School Board, where his knowledge, his earnestness, and the excellence of the objects he had in view, no less than the keenness of his intellect and his ready mother wit, soon taught his antagonists—and they were many at first—that he was a dangerous opponent. Still more recently the duties of President of the Royal Society and Inspector of her Majesty's Fisheries have been added to his other labours. He is about, we believe, to start for Venice, and we are sure the good wishes of our readers will go with him, that he may thoroughly enjoy his well-earned rest, and return perfectly restored to health.

DEATH OF PROFESSOR SOMMA.

To all who have watched the development of pædiatric studies in Italy, the sad intelligence of the death of Professor Luigi Somma of Naples, the founder and director of the recently established periodical devoted to the study of diseases of children, and entitled "Archivio di Patologia Infantile," will bring feelings of sincere regret and sympathy. A victim to cholera, the scourge which has so devastated the beautiful city in which he lived and laboured, he fell at the post of duty and of honour on Sept. 19th last, in the flower of his age, and in the midst of his philanthropic work.

NOTIFICATION OF DISEASE IN SUNDERLAND.

THE question of Notification of Infectious Disease is being discussed in Sunderland as part of a local Bill. So far as we can gather from the incomplete reports in the local papers, the profession in Sunderland is quite willing that the medical man should act in concert with the responsible householder, and at his request, but is much dissatisfied that the clause of the Bill should have been altered, as it has been, so as to allow anyone, even in a tenemented house, to require the medical attendant to act. We think that the medical men have shown great public spirit in agreeing to act with the householder in a matter in which the latter alone should be held responsible. But it will be intolerable to allow more than one person in the house to claim the action of the medical man. We trust the Town Council will see

Digitized by Google

the reasonableness of consulting the feelings of medical men in this matter, and will not strain their good nature too far when they show so much disposition, as in Sunderland, to co-operate with the public sanitary authorities. Are we right in gathering from the reports that the Town Council is proposing either to give them no fee, or to cut them off with a shilling fee, for one of the most responsible and troublesome duties that can devolve on liberal-minded men. Surely great communities in using medical men to save them from infection ought to pay a fee which the medical man can accept with self-respect.

THE PAYMENT OF MEDICAL WITNESSES.

THERE can be no doubt that the law regulating the attendance of medical men and the payment of their fees for giving evidence in the courts is exceedingly vexatious. A short time since we drew attention to the anomalous state of affairs as regards the remuneration that a qualified man can claim for the aid he renders to the administration of justice. There is, however, a very distinct principle recognised by the highest legal authorities—viz., that a medical man is compelled under subpœna to testify to facts within his knowledge. Nor does this apply alone to our own profession. Even the Lord Chancellor could be summoned under such circumstances. It is certainly hard that a medical man should be compelled to leave his bed during the small hours of the morning to dress perhaps a cut head received in a common street quarrel, and then because he has given timely succour—it may be without compensation—that advantage should be taken of the knowledge of which he has become unwillingly possessed to compel his attendance as a witness in a county court or before a magistrate. We hold that the courts should have power not only to order a reasonable fee for the witness, but also to enforce the payment of such fee.

MEDICAL AND PHARMACEUTICAL EXHIBITION.

ON Monday last a Medical, Pharmaceutical, and Kindred Professions and Trades' Exhibition was opened at Humphrey's Hall, Knightsbridge. The Exhibition is said to be held in aid of the funds of University College Hospital; and its aim is to bring before the professions and trades concerned, as well as the public, the specialities of each particular class of exhibitors. The exhibit of leading interest was a portable iron hospital, erected by Mr. J. C. Humphreys, of Albert-gate, S.W. The model building is constructed externally of corrugated iron and is lined with wood. It contains a male ward and a female or children's ward; each would accommodate four patients. There are also a matron's room, a kitchen and scullery, with other offices. The cost of the whole would be about £300. Such a building can be constructed in a very short space of time, and there is a corresponding facility in moving it from site to site. We shall on another occasion devote a special article to the various exhibits at this Exhibition, which will remain open till Nov. 12th.

STATISTICS OF CHOLERA IN ITALY.

CONSIDERING the brevity of its duration, according to *La Gazzetta degli Ospitali*, the present epidemic of cholera in Naples has exceeded in severity all previous invasions, including the terrible one of 1837. That was the cause of 13,800 deaths in five months. The first death from cholera in Naples this year occurred on the 21st of August. From that day to midnight, Sept. 30th, the cases numbered 10,957, and 5778 deaths. In the hospitals the recoveries were 1121, the deaths 787. The actual population of Naples is 500,000. At Torre Annunziata 137 deaths occurred in 234 cases. From the 1st to the 30th of September 294 soldiers of the Naples garrison were attacked with cholera, 134 of them fatally. The mean mortality was 42 per cent. In the aristocratic quarter of Chiaja, during the whole of September 162 deaths occurred amongst 252 cases of cholera. By far the greatest number of victims were women. The municipality distributed 12,573 shirts, 14,505 sheets, 5484 blankets, and 1109 mattresses. The money contributions to the City relief fund amounted to £22,010, and to the White Cross Society £4822.

THE ALBERT MEDAL.

THE Albert Medal of the Second Class has been conferred on William Macgregor, M.D., C.M.G., chief medical officer and receiver general, Fiji, for having at the imminent risk of his own life rescued from drowning the captain and a passenger of the emigrant ship *Syria*, which on May 11th was stranded upon the Nasalai reef, some twenty-three miles to the eastward of Suva, Fiji. It is stated that but for the energetic, able, and cool way in which Dr. Macgregor led the relieving party, the loss of life, which was great—fifty-nine in all—must have been appalling.

M. GAVOY'S STETHOSCOPE.

AT a recent meeting of the Académie de Médecine, M. le Baron Larrey gave in a sealed letter containing a detailed description of a new form of stethoscope invented by M. Gavoy. The instrument is stated to be a telephone in miniature. The thoracic sounds, pulmonary or cardiac, are said to be amplified without being exaggerated by its means; the quality of the auscultatory signs is also believed to be unaltered.

MICRO-ORGANISMS AND DISEASE.

WE are pleased to find that Dr. Klein has published in book form the chapters on micro-organisms and disease which for the past few months have formed so attractive a feature of our contemporary, the *Practitioner*. The book ("Micro-organisms and Disease," Macmillan and Co, 1884) is very handy and compact, and abounds in illustrations, nearly all of which are original.

"GAYTHORNE HALL" is the title of a novel lately issued. It is the product of the fertile pen of a London physician, whose medical writings are well known for their original and vivacious character. The novel is a political one, dealing with the times of the Chartists, and the scene is laid in the North Country, where its author was, we believe, born and bred. The story told is not wanting in elements of sensation, but the author is to be commended for the care with which he has adhered to the historical facts that give the book a value and interest often lacking in fiction. It is dedicated to Oliver Wendell Holmes, of all medical men the foremost amongst those who have enriched general literature.

A DINNER for the reunion of old past students of the Meath Hospital and County Dublin Infirmary will be held on Monday, November 3rd, at the Shelbourne Hotel, at seven o'clock; William Moore, M.D., President of the King and Queen's College of Physicians, will preside. Mr. L. Hepenstal Ormsby, F.R.C.S., 4, Merrion-square West, Dublin, is honorary secretary.

THE American Academy of Medicine will hold its ninth annual meeting on the 28th and 29th inst. at the Johns Hopkins University, Baltimore, under the presidency of Dr. Benjamin Lee. The list of papers to be read include subjects of great practical interest to the medical profession throughout the world.

Digitized by Google

DURING the past fortnight over one hundred cases of typhoid fever have been reported at Derby. The fever ward at the infirmary is full, but it is stated that during the past few days the outbreak has slightly abated.

DR. WILSON FOX read a most interesting and practical paper on the treatment of pneumonia at the annual meeting of the University College Medical Society on Wednesday night last.

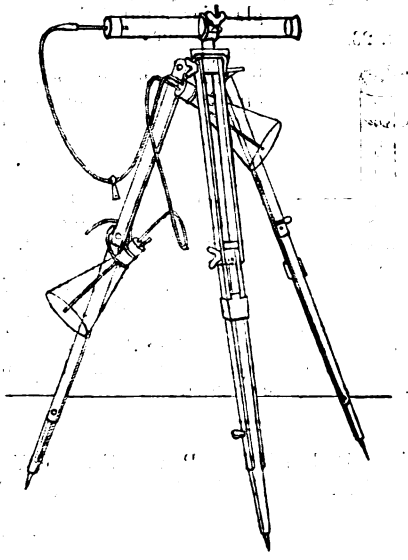
DR. PARSONS, on behalf of the Local Government Board, has paid a second visit to Kidderminster for the purpose of thoroughly investigating the cause of the recent epidemic of enteric fever.

THE Gulstonian Lectures for 1885 will be delivered at the College of Physicians by Dr. Osler of Philadelphia; the Croonian by Dr. Herman Weber; and the Lumleian by Sir Andrew Clark.

SIR JOSEPH LISTER, Bart., is announced to read a paper at the opening meeting of the session of the Medical Society of London on Monday next.

THE BIOLOGICAL LABORATORY AT THE HEALTH EXHIBITION.

No. VI.



CULTIVATING MEDIA—(*continued*).

Gelatinised Meat Infusion may be used in a variety of ways. The modes of preparing test-tube cultivations and slide cultivations are described in the footnote on pp. 251 and 252 in THE LANCET of Aug. 9th. It may also be used for obtaining pure cultivations of different kinds of bacteria occurring in a fluid.

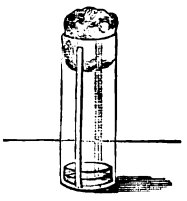
The way in which this is done may be illustrated by the method of *testing water*. The contents of a tube of the infusion which has been rendered sterile by steaming are gently heated to the melting-point. Some of the water to be tested is then drawn up into a pipette which has been sterilised by heat, and a drop is allowed to fall into the test-tube, the cotton-wool plug being removed for the purpose. (It is important in estimating the number of organisms in different specimens of water to use the same pipette throughout, or to measure the volume of the drop, in order that the amount of water added may be the same in each case.) When the drop has been added the tube is briskly shaken, so that the water may be thoroughly mixed with the infusion, and the contents are then poured out on the surface of a sterilised glass plate[1] (about 5 in. by 6 in. in area), which has been previously placed at the bottom of one of the flat glass dishes described above. In order that the liquid may not run off the plate it is made level by means of a levelling stand, on which the dish is supported, and a spirit level. When the infusion has been poured on the plate the cover of the dish is replaced, and the whole is allowed to stand. In the course of a day or two, the period varying with the temperature, there appear dotted about in the thin layer of solid gelatinised infusion the colonies formed by the multiplication of the organisms which were contained in the drop of water. These may be recognised by their naked-eye characters, assisted if necessary by microscopical examination and further cultivation. In this way the number and nature of the organisms present in a sample of water may be estimated and ascertained. In order to obtain a pure cultivation of an organism occurring among a number of others, the method is exactly the same, cultivations being made from the colonies which appear. Each of these consists of only one form, as the organisms are separated from one another when the drop is shaken up with the gelatinised infusion to which it is added.

The gelatinised meat infusion is also employed in the methods of testing air. With Dr. Hesse's apparatus (Fig. 25) the bacteria contained in a measured quantity of

FIG. 25.

Dr. Hesse's apparatus for testing air.

air are examined. It consists of a wide glass tube, which is supported on a portable stand, and an apparatus for sucking air through the tube. One end of the tube is closed by two indiarubber caps. The inner cap is perforated in the centre by a hole about three-eighths of an inch in diameter. The outer cap is not perforated, and covers the inner one. Into the other end fits a caoutchouc stopper, which is pierced by a piece of glass tubing, and this is connected by an indiarubber pipe with the upper of two flasks, which are attached to the stand, and constitute the apparatus by means of which air is sucked through the tube. The flasks are similar to one another. They are of one litre contents, and the mouths are closed by caoutchouc stoppers perforated by two glass tubes. One of these tubes is short, and the other reaches to the bottom of the flask. The indiarubber pipe mentioned above passes to the shorter of the tubes, piercing the stopper of the upper flask. Another pipe connects the long tube of the upper with the long one of the lower flask. In preparing the apparatus for testing air the wide glass tube is removed from the stand and the indiarubber pipe is disconnected from it, the tubing piercing the stopper being plugged with cotton-wool. A quantity of gelatinised meat infusion is then introduced into the tube and made to flow about until the whole of the interior is wetted by it. When this has been done the tube, with both the caps adjusted, is placed in the steaming box and steamed for half an hour on three days in succession, in order to sterilise it. As the infusion is solidifying after the third steaming, the tube is rotated about its long axis, so as to line the interior with a layer of the infusion. In using the apparatus the tube is placed on its stand, the cotton-wool plug withdrawn from the glass tubing, and the indiarubber pipe fixed thereon. The upper flask is then filled with water till it contains one litre. The apparatus having been placed in the air to be tested, the outer of the two caps closing one end of the wide tube is removed, and the upper flask is tilted until the water flows into the lower one. When once the flow has commenced the syphon arrangement of the tubes causes it to be continued, and air is by this means drawn through the tube to replace the water in the upper flask. Any bacteria in the air are carried against the gelatinised infusion on the sides of the tube, and there stick. When the upper flask is empty, the flow may be re-established by reversing the position of the flasks. The rate of the flow may be regulated by a screw-clamp attached to the indiarubber pipe between the tube and the upper flask. In this way any quantity of air may be made to pass through the



[1] The glass plates for this purpose are placed in a sheet-iron box and then heated for three hours to 150° C. They are kept in the box until they are used.

Digitized by Google

tube. When sufficient air has passed the outer cap is replaced, and the tube may be dismounted and set aside. In the course of a few days colonies of different kinds of organisms spring up in the gelatinised infusion, resulting from the multiplication of those contained in the air. These may then be counted and recognised.

A simpler but less accurate method is to expose a dish of gelatinised infusion to the air for a measured length of time, so as to allow the falling dust to settle on it. The apparatus is represented in Fig. 26. It consists of a tall glass jar, a flat dish, which can lie at the bottom of the jar, and a brass lifter, by means of which the dish can be raised and lowered. The whole apparatus is first plugged with cotton-wool and then heated to 150° C. for three hours. The cotton-wool is then removed, and the dish having been raised to the mouth of the jar, the contents of a sterilised test-tube of gelatinised meat infusion, liquefied by heat, is poured into it. The dish is then carefully lowered and the plug reinserted. When the infusion has become solid, the jar is placed in the air to be examined, and the cotton-wool plug removed from the mouth for a measured length of time, and then replaced. In the course of a few days the organisms develop and form colonies, which may be counted and recognised.

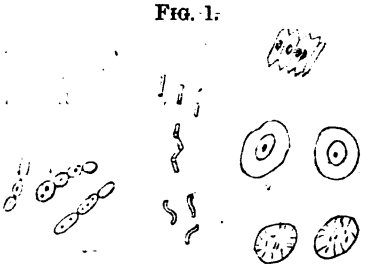
FIG. 26.

Apparatus for testing air.

PROFESSOR FILIPPO PACINI'S NEW MICROSCOPICAL OBSERVATIONS ON CHOLERA.

UNDER the above title Dr. Aurelio Bianchi of Florence has just collected and published some manuscript observations made by his late teacher during the cholera epidemic which prevailed in Florence in 1855. The editor claims that Pacini was the first who instituted microscopic researches with a view to discover the nature of the Asiatic plague, and that he described with much precision and truth, under the generic name of vibrio, the organisms now known as microbes.

The discoverer of the Pacinian bodies deservedly established such a reputation amongst the original observers of his age, that special interest must be felt in Dr. Bianchi's small volume just issued (with the imprint 1885), by Vallardi of Milan. Having been favoured with an early copy, we purpose giving a summary of its contents, with a reproduction of some of the illustrations, so that our readers may form a just idea of the author's descriptions.



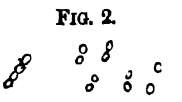
In a prefatory letter which Pacini addressed Sept. 12th, 1855, to Professor G. B. Ercolani of Bologna, he insists that it is no use searching for the specific cause of cholera in the excreta; but it must first be sought in the mucous membrane, the superficial destruction of which is the *pathological condition* of cholera. After the mucous membrane observations may be profitably instituted in the excreta, in the air, and in potable waters.

The first observations were made on the cadaver of M. G——, aged sixty, who died of Asiatic cholera in Florence, Feb. 12th, 1855. The attack lasted nineteen hours. The body was greatly emaciated and slightly cyanotic towards the extremities and the head. The right ventricle of the heart contained a loose fibrinous clot, with some black and almost pitchy blood. The stomach was nearly empty, but the small quantity of fluid which it contained was preserved. The intestines presented a livid red colour; the liver was greatly enlarged. The small intestines were almost completely empty, their inner surface almost wholly covered with mucus, but here and there could be seen the villi, of a scarlet-red colour and denuded of epithelium. The colon also was nearly empty. The parts submitted to the microscope were a small quantity of blood, the fluid from the stomach, and the small and large intestines, a piece of the anterior wall of the stomach, a portion of the small intestine about its middle, also its inferior extremity, the cæcum and its appendix.

These parts were placed in the following preserving solutions:—The blood in acetic acid 1, sublimate 2, glycerine 34, water 792·6; the fluid of the stomach, the small and large intestine in sublimate 1, salt 5, water 300; a part of the fluid of the colon in acetic acid 1, sublimate 2, glycerine 34, water 1000; another part of the fluid of the colon in sublimate 1, acetic acid 2, glycerine 17, water 500. Finally, pieces of stomach, small and large intestine, in sublimate 1, salt 5, water 300; and a small portion of the small intestine in sublimate 1, acetic acid 2, glycerine 17, water 500

On comparing the blood with healthy blood treated in the same manner, the microscopic appearances were not different. In the fluid from the stomach were (1) a large number of torula cerevisiæ; (2) in the mucus attached to the walls of the stomach were small masses of sarcina ventriculi, but none were found free in the fluid; (3) an immense quantity of vibrios, also found in the small and large intestines (fig. 1 represents the three appearances just referred to);

FIG. 1.



(4) small needle-formed bodies or spiculæ, like small elongated naviculæ, which were perfectly rectilinear and pointed; they strongly reflected light, but their motility could not be certified; in length they varied from 0·030 to 0·040 mm.; (5) epithelial cells from the stomach, in small quantity and much altered; (6) some epithelial cells from the mouth or œsophagus, with vibrios attached to them. In the mucus from the stomach the microscope displayed granular globules and cylindrical cells; also some masses of sarcina and a very large number of vibrios. A large quantity of vibrios was also found in a portion of the mucous membrane.

Of the vibrios met with in the fluids of cholera subjects Pacini gives (pp. 18, 19) the following description:—"Under a strong magnifying power (800 to 1000 diameters) these vibrios closely resemble a fragment of a fibril of a striated muscular fibre. In fact, every vibrio is represented by a series of exceedingly small globules, almost always perfectly distinct under that magnifying power, but sometimes a little less distinct. The smallest of these vibrios are formed of two or three globules; those of only one globule cannot be distinguished from other molecules of equal size. I have also found some formed of more globules, even as many as twelve or eighteen. When they are formed of six or seven globules they are not perfectly rectilinear, but slightly curved. Those formed of ten or twelve globules are, as a rule, slightly bent, in S or other shape.

Vibrios in which the globules are not very distinct are almost perfectly rectilinear. Perhaps the formation in globules and flexion is a commencement of division. One of these vibrios of four globules was 0·005 mm. long, and the diameter of these globules was a little less than 0·001 mm. The granular masses which are found in the ejecta, if transparent, may be recognised as masses of vibrios."

In order to examine with more accuracy the finest vibrios, Pacini caused the liquid to evaporate after it had been obtained from the mucous membrane. The vibrios were then specially evident, but they presented the following varieties, being all of the same diameter:—From 0·0005 to $\frac{1}{2000}$ mm. in length. The greater part, however, seemed formed of two slightly lengthened globules, and which sometimes were a little pyriform—that is, a little thicker at one end than the other. Of these also he saw a chain of four, as in Fig. 2, but the greater part were simply coupled, and thus united had a length of a little less than 0·002 mm. There were also an infinity of small isolated globules, which probably resulted from the division of the preceding. Sometimes the division of two globules was indistinct, and only indicated by a slight constriction, so as to give the appearance of a fine

FIG. 2.

Digitized by Google

about 0·002 mm., and slightly narrowed in the middle and swollen at the ends. At other times these small globules were round rather than pyriform, and either isolated or united in twos and threes. Usually in the latter case the middle one was the smallest. At other times Pacini has seen some of these molecules which were lengthened and cylindrical and about 0·0015 mm. in length, but with a very slight indication of division in the middle. It is probable that all these varieties were only differences in development. When dried, the larger and more refracting globules referred to above disappeared.

FIG. 3.

In the vomit of another cholera victim were found an immense quantity of vibrios, which resembled the *vibrio rugula*. Some filaments had the appearance of an alga. (Fig. 3.) The detailed clinical and microscopical observations which constitute the remainder of the monograph are substantially confirmatory of the preceding ones.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

During the week ending the 11th inst., 5322 births and 3319 deaths were registered in twenty-eight of the largest English towns. The annual rate of mortality in these towns, which had been 19·1 and 20·1 per 1000 in the two preceding weeks, declined to 19·8 last week. During the thirteen weeks of last quarter the death-rate in these towns averaged 22·8 per 1000, against 20·6 and 19·9 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 10·9 in Halifax, 14·9 in Birkenhead, 16·2 in Bradford, and 16·5 in Portsmouth. In the other towns the rates ranged upwards to 26·0 in Leeds, 26·2 in Preston, 30·9 in Sunderland, and 31·6 in Blackburn. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which in the seven preceding weeks had declined from 1311 to 548, further fell to 477 last week; of these, 222 resulted from diarrhœa, 76 from "fever" (principally enteric), 54 from scarlet fever, 47 from whooping-cough, 38 from measles, 31 from diphtheria, and 9 from small-pox. These diseases caused the lowest death-rates in Halifax and Birkenhead, and the highest in Derby, Newcastle-upon-Tyne, and Leeds. The highest rates of mortality from scarlet fever were recorded in Newcastle-upon-Tyne and Cardiff; from measles in Bolton and Preston; from whooping-cough in Sunderland; from "fever" in Salford and Derby; and from diarrhœa in Birmingham, Sunderland, and Hull. The 31 fatal cases of diphtheria in the twenty-eight towns included 16 in London, 3 in Liverpool, and 3 in Leeds. Small-pox caused 9 deaths in London (excluding 2 London cases registered outside Registration London). The number of small-pox cases in the metropolitan asylum hospitals situated in and around London, which at the end of the two preceding weeks had been 536 and 533, further declined to 504 on Saturday last; the new cases admitted were 68, against 129 and 106 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 162 and 182 in the two preceding weeks, further rose to 227 last week, but were 54 below the average. The causes of 71, or 2·1 per cent., of the 3319 deaths registered last week in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Leicester, Oldham, and in eight smaller towns. The largest proportions of uncertified deaths were recorded in Wolverhampton, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·0 and 21·1 in the two preceding weeks, rose to 22·8 in the week ending the 11th inst., and exceeded by 3·0 per 1000 the mean rate during the same period in the twenty-eight large English towns. In the Scotch towns the rates last week ranged from 13·3 and 18·3 in Leith and Dundee to 25·9 in Paisley and 27·8 in Glasgow. The 551 deaths in the Scotch towns included 32 which resulted from diarrhœal diseases, 21 from "fever," 20 from measles, 20 from whooping-cough, 15 from diphtheria, 12 from scarlet fever, and not one from small-pox; in all, 120 deaths were referred to these principal zymotic diseases, against 131 and 137 in the two previous weeks. These 120 deaths were equal to an annual rate of 5·0 per 1000, which exceeded by 2·2 the average rate from the same diseases last week in the twenty-eight towns. The deaths referred to diarrhœa, which in the two previous weeks had been 52 and 56, declined last week to 32, of which 15 occurred in Glasgow and 6 in Edinburgh. The 21 fatal cases of "fever" exceeded by 7 the number in the preceding week, and included 16 in Glasgow. The 20 deaths from measles showed a further increase upon those returned in the two previous weeks; 11 occurred in Aberdeen and 8 in Glasgow. The 20 fatal cases of whooping-cough showed a slight increase, and included 13 in Glasgow. Of the 15 deaths from diphtheria, 8 were returned in Glasgow and 3 in Aberdeen. The 12 fatal cases of scarlet fever all occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight Scotch towns showed an increase, but were considerably below those returned in the corresponding week of last year. The causes of 100, or more than 18 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which in the two preceding weeks had been 30·2 and 26·3 per 1000, rose to 28·8 in the week ending the 11th inst. During the thirteen weeks of last quarter the death-rate in the city averaged 25·4 per 1000, the rate during the same period being 20·9 in London and 17·0 in Edinburgh. The 194 deaths in Dublin last week included 32 which resulted from the principal zymotic diseases, against 36 and 49 in the two previous weeks; of these, 15 were referred to diarrhœal diseases, 11 to scarlet fever, 4 to "fever," and 2 to whooping-cough. These 32 deaths were equal to an annual rate of 4·8 per 1000, the rate from the same diseases being 1·9 in London and 2·3 in Edinburgh. The fatal cases of scarlet fever, which had been 11 and 7 in the two previous weeks, rose again last week to 11. The deaths from "fever," which had increased from 1 to 8 in the three preceding weeks, declined to 4 last week. Eleven inquest cases and 5 deaths from violence were registered in the city during the week, and 43 deaths occurred in public institutions. The deaths of infants showed a slight decline, while those of elderly persons considerably exceeded the numbers in recent weeks. The causes of 31, or nearly 16 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ADMIRALTY.—The following appointments have been made:—Staff Surgeon John Kelly Conway, to the *Himalaya;* Surgeon Thomas Lyle Horner, to the *Dreadnought;* Surgeon Geo. Despard Twigg, to the *Mallard;* Surgeon Alex. John J. Johnston, to the *Dreadnought;* Staff Surgeon Richard W. Coppinger, M.D., to the *Nelson;* Staff Surgeon Horace E. Y. Cross, to the *Diamond;* Staff Surgeon Valentine Duke, M.B., to the *Vernon;* Staff Surgeon Robert W. Biddulph, M.B., to the *Duncan;* Surgeon James L. Smith, M.B., to the *Starling;* Surgeon William W. Jacobs, to the *Asia;* Surgeon Henry G. Strickland, M.B., to Plymouth Hospital; Surgeon George Y. Dean, M.B., to the *Achilles;* Surgeon John P. J. Coolican, to the *Minotaur;* Surgeons Robert A. Simpson and Francis J. Lea, to the *Nelson;* Surgeon Edgar Ralph Disney, to the *Diamond;* Charles Dundee to be Surgeon and Agent at Whitehead and Hillsport; William Stewart, M.B., to be Surgeon and Agent at Kirkwall, N.B.; John W. Wood to be Surgeon and Agent at Ramsey, Isle of Man.

ARTILLERY VOLUNTEERS.—1st Lancashire: Surgeon and Honorary Surgeon-Major Henry Hulme has resigned his commission.—1st Caithness: William John Henderson-Sinclair, Gent., M.B., to be Lieutenant.

RIFLE VOLUNTEERS.—1st Isle of Man: Albert Primrose Wells, Gent., M.A., to be Acting Surgeon.—2nd Volunteer Battalion (the York and Lancaster Regiment): Acting Surgeon William Makeig Jones resigns his appointment.

"Audi alteram partem."

SMALL-POX AND BLINDNESS.

To the Editor of THE LANCET.

SIR,—Within a month I have seen at University College Hospital, and at the Moorfields Eye Hospital, three cases in which, in addition to very deep scarring of the face, the sight of both eyes has been completely and irretrievably lost from recent attacks of small-pox. In two of the cases vaccination had not been performed, and in the third there were only three slight, almost inappreciable, vaccination marks on the arm. The unvaccinated cases were children about eleven years of age; the other case was a man aged twenty-nine years. Each case has its own peculiar lesson, but taken as a group the three cases are very significant and instructive. In only one was non-vaccination deliberate and culpable; in the other vaccination had been attempted but did not "take," and was not repeated. The circumstances of the case in which vaccination was wilfully omitted are noteworthy, and afford a striking proof of the malignancy of small-pox uninfluenced by vaccination, of the modifying influence of vaccination, even where it fails to afford complete protection, and, lastly, of the necessity of revaccination. The victim was a boy aged eleven years, the second of four children, and the only one in the family who had not been vaccinated. The other children had all been vaccinated in infancy, but in the case of this boy "the father objected" for some unexplained reason. Both parents were vaccinated in childhood and have not had small-pox. Last June the eldest child, aged about thirteen years, took small-pox, but "had it very slight; only queer about a week"; then the third child was seized, "it was only a bit queer for about a week," and then the second child (my patient) took it and was very ill and is now totally blind from collapsed and shrunken globes. The youngest child, aged seven, and therefore vaccinated within seven years, escaped altogether though exposed to the contagion for a period of many weeks. These "facts" speak for themselves. As showing the kind of mind that has an affinity for anti-vaccination arguments, I may state that the father of the child subsequently called at the hospital to tell me that he had "great hopes of his boy's sight even yet," and in reply to a question said "that some women were curing him by bathing the eyes."

I am, Sir, yours truly,

Harley-street, W., Oct., 1884. JOHN TWEEDY.

"BICYCLE RIDING AND PERINEAL PRESSURE: THEIR EFFECT ON THE YOUNG."

To the Editor of THE LANCET.

SIR,—Dr. Allbutt in his letter of September 27th says, "There are many men who have been great cycle riders from the times of the old 'dandy horse' to the present period, and are in the enjoyment of remarkably good health, both of mind and body." To this there are two answers—viz., that given by Dr. Strahan in his letter of Oct. 4th: that those in question commenced riding the modern machines at an adult age, and it was chiefly to the growing youth that our theories applied; and my own answer, that it is logically impossible to prove a universal rule by adducing particular instances.

Dr. Boothroyd says: "With regard to the spinal shocks made much of by Dr. Strahan, their influence is of a still more hypothetical nature." It is only quite recently that we have begun to study and understand the true nature of functional nervous diseases, yet it is already a fact well established and known to those who have much experience in the treatment of nerve-troubles that continued longitudinal vibrations communicated to the spinal cord are very injurious, and frequently set up a peculiar condition termed neurasthenia. In fact, so well is this a recognised fact that a special name has been coined, and these cases are commonly called "railway spine," particularly in America, from excessive travelling being the most frequent cause. Up to quite recently these cases were entirely misunderstood and classed as cases of dyspepsia, hypochondria, hysteria, &c. I have no hesitation in saying that in these days of competition for a livelihood and of competitive examinations, neurasthenia is really one of the commonest and most important complaints that we have to treat. Important, because a functional nerve trouble so frequently precedes an organic lesion, and if recognised in the first stage can so often be cured. These cases of railway spine—or as we shall, I am afraid, soon have to call them cyclist's spine—can be easily diagnosed by attention to the following points. In nearly every case you will find an increase in the quantity of urea excreted; sometimes as much as twenty grains per ounce is present. In most cases the secondary rise in the pulse trace as shown by the sphygmograph is nearly or quite absent, showing want of tone of the vaso-motor system of nerves, and other symptoms are generally present, such as flatulence; sometimes the stomach becomes enormously distended with wind, probably from some impairment of the functions of the vagus nerve, gastralgia, melancholy, feeling of "clutching" at the throat, with occasionally agarophobia and claustrophobia. No doubt dyspepsia is always present, but it is secondary, and caused by the nerve trouble. These cases recover readily by the use of nerve tonics, such as valerianate of soda, hypophosphite of soda, &c. Such being the case, and seeing how easily this disease may be referred to some cause other than cycling, when the physician has never dreamt that the latter was even capable of producing such a state, and consequently never thought of asking the patient whether he rode a machine, can we logically say that because up to the present time not many cases have been observed and traced to their true source, they are really very few in number? On the contrary, I believe that now the attention of medical men has been directed to the subject, and they know what to look for, we shall hear of many cases of neurasthenic dyspepsia among cyclists.

But however badly the present machines may vibrate, we are threatened with a great aggravation of the evil in the immediate future. The tricycle, like other things, arrives at its final form by a process of evolution. Its wheels are becoming smaller, but are made to revolve faster by a method of chain gearing. This is called, technically, "gearing up." Of course, the smaller a wheel is, the greater number of shocks are given in travelling a given distance at the same speed. This principle has been this year applied to bicycles, and one called a "safety" produced. Owing to the successful result of a race recently run on the latest of these, there is every probability of the market being inundated with several makes of these early next year, in some of which, I am informed, the principle has been carried to a very great excess, and the wheels made extremely small, with the effect of enormously increasing the number of shocks per second. If the makers ever succeed in producing a saddle and spring which will minimise the vibrations reaching the trunk, there will be still left those proceeding from the steering-handle of the machine to the hands and arms of the rider, and which I am inclined to think may be found to be even more disastrous in their results than the former. I have been informed by cyclists, and have myself observed, that in riding rough roads the vibration of the handle-bar has produced sensations like slight electric shocks in the hands and forearms. Now, although there may not have been much damage done by the comparatively slow vibrations of the present machines, yet when we come to the universal use of the small-wheeled "safety," doing one hundred miles in a little over seven hours, over rough roads, with its enormously quicker rate of vibrations, we may expect to see soon some tangible results.—Yours faithfully,

GEORGE HERSCHELL, M.D. Lond.

Moorgate-street, Oct. 6th, 1884.

To the Editor of THE LANCET.

SIR,—Will you allow me, as a practical bicyclist with considerable experience both of cycles and cyclists, to make a few remarks on the letters of Dr. Strahan, and others, on this subject. I quite agree with Dr. Strahan that attention requires to be drawn to the excessive use of bicycles by young growing boys, so many of whom ride bicycles too big for them, and with improperly constructed saddles. I beg, however, to entirely disagree with his opinions on the ordinary bicycle saddle, the manner in which it is sat upon, and the pressure it exerts on the perineum. He says, "The

Digitized by Google

bicycle saddle is reduced to the smallest possible limit," that "it is just wide enough posteriorly to cover the ischial tuberosities, and it tapers off quickly to a long narrow horn in front on which the perineum rests;" but I hold, on which the perineum ought not to, and in the majority of bicycle saddles does not, rest. I maintain that a properly constructed bicycle saddle is an ideal seat, there being just as much as is necessary to sit comfortably upon, and no more. The anterior horn might be done away with if it were not for its use in fastening the saddle to the machine and keeping it steady in its place. In a properly constructed saddle the posterior part on which the ischial tuberosities rest ought to be as high as, or a little higher than, the level of the anterior narrow part. It should not, however, be carved up so much behind as to cause the tuberosities to slip forwards, such as is the case in some saddles on light racing machines. The anterior narrow part should rest on, and be closely applied to, the spring of the bicycle, and should not project or turn upwards at all. These conditions are fulfilled in the well-known and widely used "suspension saddles," and in the majority of saddles supplied with good class machines. Now, as to the manner a bicycle saddle is sat upon, I find by testing it when riding that when in an upright position there is a space of nearly two fingers' breadth between any part of my saddle and my perineum, and when leaning forwards going up hill there is still over one finger's breadth between. When leaning forwards the ischial tuberosities are not, as Dr. Strahan says, raised from the saddle at all, but a portion of the tuberosities, slightly more anterior than when in the upright position, is pressed upon. The only exception to this is when, by pulling on the handles, the whole body is raised up off the saddle and the whole body weight thrown on the descending pedal—standing on the pedals in fact, a method adopted by many good bicyclists when riding up a long incline, in order to save by the use of the weight an unnecessary expenditure of muscular energy. I find that when sitting on the saddle the tip of the anterior horn of the saddle is 4 in. in front of the origins of my long adductor muscles, and that therefore the anterior horn, which is only 3½ in. long, is entirely untouched by me.

Dr. Strahan imagines the leg is vertical when extended, and that therefore a properly made saddle, as suggested by Dr. Herschell, is impossible. Now, although it may be the case on some tricycles, yet the leg cannot be quite vertical when extended on the pedal, as the portion of the saddle sat upon is at least nine inches behind a vertical line drawn from the centre of the wheel.

With regard to Dr. Herschell's two cases, I would suggest that the stricture in the youth was due to an injury caused by slipping when getting on, or to his racing machine being too big for him; and that the stricture in the middle-aged man had some predisposing cause, or was due to his riding with his tricycle saddle raised too high or improperly inclined back.

I quite agree with Drs. Allbutt and Boothroyd that the healthy, vigorous out-door exercise of cycling acts as an anaphrodisiac, which more than counteracts the effects of any local excitation, if there be any, which I doubt. The influence of the "spinal shocks," so often talked about, is quite theoretical. On an ordinary road these shocks do not have any effect; if they did, they would cause nervous exhaustion on a long ride, which we find is not caused. The jolts, although perhaps more numerous, are much less than on horseback. What horseman, even with a change of horses, could ride a hundred miles a day for several consecutive days, a comparatively common feat on a bicycle—as, for instance, the distance of 930 miles, from Land's end to John-o'-Groat's, ridden by two bicyclists, one doing it in 6 days 23 hours, the other in 6 days 21 hours?

I am, Sir, yours truly,

GEORGE B. BATTEN, M.B., C.M.,
Late Sub-Captain, Edinburgh University Cycling Club.
Fife and Kinross District Asylum, Cupar, Oct. 6th, 1884.

"THE EXAMINATION OF SURGEONS-MAJOR."

To the Editor of THE LANCET.

SIR,—Almost invariably I allow anonymous communications to pass unnoticed, for the reason that I consider a writer who lacks the courage of his opinions sufficient to permit of his putting his name to his writings is beneath the notice of ordinary straightforward men. To this rule I am now reluctantly constrained to make an exception, as some unknown quantity, behind a shield of "X. Y. Z." has written to you in your issue of the 4th his views and opinions of my letter to you upon the subject of the examination of surgeons-major. Those views and opinions might be silently ignored in consideration of their innocuous imbecility, were it not that, in addition to his own ideas, "X. Y. Z." attributes to me criticisms upon the *Army Circular* of August 1st, 1884, to which I desire emphatically to disclaim any authority. I am supposed by your correspondent to look upon the knowledge of operative surgery and the practice of medicine in the minds of surgeons-major as parallel with the knowledge on the part of lieutenant-colonels of the goose-step. I expressed myself to the effect that questioning the knowledge of surgeons-major in operative surgery and practical medicine was parallel with questioning the knowledge of lieutenant-colonels of the goose-step. The fact of examining men in a subject implies a doubt as to their knowledge of the same; it is against this doubt that I protested. "X. Y. Z." is erratic in his mention of promoting surgeons-major from "executive to administrative rank," the rank of brigade surgeon being strictly speaking executive. He is also erratic in suggesting that surgeons-major should follow my example by taking the F.R.C.S.I., as no such suggestion or option appears in the circular connected with surgeons-major over twenty years' service. Your correspondent remarks that "it seems to be intended," &c. He can form his own opinions as to what "seems to be intended," without very materially altering those of many who are interested in the design and purport of the circular. Again, "X. Y. Z." informs us that "the Director-General does not seem," &c., and that "the Director-General appears to be perfectly satisfied with the qualifications to be obtained from any of the recognised colleges." If so, somebody ought to mention the fact, as it no where appears in the circular. Is there a germ of the mushroom growth, of which I have already spoken in this sudden inspiration, of what "seems" and "appears" to take place in the minds of those occupying "high places" in the department? I am perfectly aware of the circumstance to which "X. Y. Z." alludes with regard to medical officers of the German Army, although I am at a loss to understand what "middle-aged German medical officers" have to do with my previous letter to you. I could congratulate your correspondent upon his great-mindedness, evinced by his facility for being "amused," were it not that his hilarity has, unfortunately for me, enticed him into wandering far from the meaning and expressions of my letter, and towards the apparently very cloudy regions of his own inventions. His letter, however, satisfactorily elicits one fact—viz., that an examination in the goose-step would be superfluous, at all events for him, so far as a doubt could be entertained of his capacity for treading in those steps. I do not intend to take further notice of anonymous communications, but should "X. Y. Z." be desirous of addressing me, and if he will do so above his name, I shall have much pleasure then in endeavouring to reduce my phraseology commensurate with his capacity.

I am, Sir, yours, &c.,

Oct. 6th, 1884. W. J. WHEELER.

*** This letter was unavoidably crowded out of our last issue.—ED. L.

"THE BEQUEST OF SIR ERASMUS WILSON."

To the Editor of THE LANCET.

SIR,—Just before reading Dr. Wilks' letter relative to Sir Erasmus Wilson's legacy to the College of Surgeons of England, I had been reading Sir Charles Bell's letters published in 1870. From one dated Jan. 1831, I send you the following quotation:—"I told you, I think, of my election into the Council of the College of Surgeons (1830). There have been three meetings since I was a member, but I restrained myself for two that I might not be too forward, and that I might comprehend fully what the College was about and how situated. Yesterday I opened upon them, and drew a picture of their situation, their array of talent, their museum, their library, then declared their inattention in not demanding a control over these institutions. I showed what these institutions were, and how they would encroach on their ancient establishment, and concluded with a hope that they would institute such courses of lectures as would extend their influence and maintain their preponderance."

I am, Sir, yours obediently,

Oct. 1884. SPES.

NEWCASTLE-ON-TYNE.

(From our own Correspondent.)

NEWCASTLE HOSPITAL SUNDAY FUND.

THE annual meeting of our Hospital Sunday Fund having been held here on Tuesday last enables me to send you further and more exact particulars as to the work of this now well-established effort for the past year. The collections were: churches and chapels, £2172 1*s.* 10*d.*; factories and workshops, £1953 18*s.* 11*d.*; the total showing an increase of £294 4*s.* 3*d.* over the collections of the previous year. It was mentioned with satisfaction by the committee and some of the speakers, that for the first time in the history of the fund the collection had passed £4000, while the total amount collected for the fund since its establishment in 1870 was £44,000. The trade depression at present prevalent in Newcastle would, it was to be feared, increase the demands on our medical charities; but it was hoped, on the other hand, that a corresponding amount of support would be given in other quarters.

THE WATER-SUPPLY AT MORPETH.

The water-supply at Morpeth for the last two months has been in a very unsatisfactory condition and deficient, the upper portion of the town having to be supplied with barrels filled at a private well. Latterly the local Board of Health has been carrying on boring operations near the Tranwell reservoirs, which only yielded enough water for one day in seven. After many disappointments water has been at last "struck," and the supply is now sufficient to dispense with the carriage by barrels. In Newcastle the water-supply has given some uneasiness lately, as it was said to be only sufficient for a month. Our gathering grounds, however, on the Northumbrian hills are so good that the copious rainfall of the last few days must have considerably replenished our supply.

MUNIFICENT GIFT TO THE DURHAM COUNTY HOSPITAL.

Mr. John Eden Beamish, hearing that the committee had resolved to increase the accommodation of the Durham County Hospital by erecting a new wing, which would cost about £2000, has, in a most generous manner, intimated his intention of placing that amount at their disposal.

NORTH OF ENGLAND MICROSCOPICAL SOCIETY.

At the opening meeting held last week a discussion took place on micro organisms, particularly bacilli and cholera microbes. As to the former, some good observers stated their ability to demonstrate their existence in the secretions of healthy persons. The whole feeling of the meeting inclined to the view that too much was attempted to be proved in late discussions, and that with the light we had many were attempting to lead in a degree it would be scarcely safe to follow. I might mention, while alluding to microscopical matters, that at a late meeting of the Berwickshire Naturalists' Club the retiring President read a paper on Salmon Disease. He (Captain Norman, R.A.) held that the burial of fish affected by the fungus at or near the banks of the Tweed was not likely to eradicate the disease, but rather to spread it, because the characteristics of the spores of Saprolegnia ferox were similar in number and vitality. They would not be destroyed, and rains were likely to wash them back into the river. He suggested "cremating stations along the banks of the river, where the affected fish might be burnt." The subject is one of very great importance, for, as is well known, the destruction of food by this disease has of late years become very serious. It has been noticed here and elsewhere by some observers that since the more general use of artificial manures in farms the salmon disease has become more prevalent, but still it is a moot point whether these facts can yet be regarded as in the relation of cause and effect. There can be no doubt, however, that the surplus moisture in land near the banks of rivers must find its way to the streams, and thus carry with it possible germs of contagion.

THE NEWCASTLE EYE INFIRMARY.

On the 13th inst., favoured by the brightest of October weather, the foundation stone of our new Eye Infirmary was laid by the Duke of Northumberland, supported by Earl Percy and the Mayor and Corporation of our City. Before the ceremony a luncheon was served in St. George's Hall, which was well attended by the public and the representatives of Law, Physic, and the Church, including two bishops, and other dignitaries I have called it the new Eye Infirmary, but the institution itself came into existence as far back as 1822, and with it are associated the names of several prominent citizens as patrons or members of the staff. During the year just ended no fewer than 4854 persons received the benefits of the charity, yet the Eye Infirmary has never yet had a house or home of its own; it has frequently shifted its quarters, but always as a tenant paying rent. The necessity of providing suitable and permanent premises has been forced on the governors by the ever-increasing demands for accommodation for their patients. The building commenced to-day is on the most complete plan of a modern ophthalmic hospital. The present medical officers are Dr. G. Y. Heath and Mr. C. S. Jeaffreson, and it is a good deal owing to their exertions and interests in the work of the charity that the foundation stone of the new building has been laid.

Newcastle-on-Tyne, Oct. 13th.

IRELAND.

(From our own Correspondent.)

THE ROYAL UNIVERSITY.

THE President of the Queen's College, Belfast, in his recent annual report draws attention to the reluctance with which the students attending his College enter for the examinations of the Royal University. One of the reasons he states is an impression, which largely prevails, that the examinations are not in all cases perfectly fair. It is said that occasionally the papers set are not entirely within the scope of the prescribed course, or free from such questions as can be answered only by those who have been specially trained in the school or class of the examiner. Another reason is that not a few of the examiners continue to teach candidates long after their examination papers have been prepared—indeed, up to the very date of examination. This is considered unfair by the students of the Belfast College, who leave that institution in June, while most of the examinations are held in September. Yet another reason is the allegation that as there are many examiners, and as their papers are prepared and printed weeks before the date of examination, the subject-matter of the papers becomes known to certain candidates, and grave injustice is thereby done to others. Whether the foregoing allegations be true or false, the President states as a positive fact that they have given rise to much dissatisfaction among candidates from the north of Ireland, and many have thereby been prevented from entering for examination. It is worthy of remark that up to the present no authentic denial of the alleged acts has been made by the authorities of the Royal University. A good many are of opinion that no examiner should lecture or give instruction in the subject he examines in; in the Royal College of Surgeons of Ireland no examiner is permitted to be a lecturer or expected to "grind" pupils for the examinations of that College, and it would be more satisfactory if these conditions were imposed on all examiners in the Royal University, at all events for the medical portion of the curriculum. The degrees of the University obtained at the recent examinations will be conferred on the 22nd inst. at the University Buildings.

QUEEN'S COLLEGE, GALWAY.

The President, in his annual report, states that the students attending the College during the session 1883-84 numbered 103, being a decrease of 41 as contrasted with that of 1882-83. For this diminution it is easy to find an adequate cause in the dissolution of the Queen's University, of which the Galway College formed a part. In the last session the students numbered 103, of whom 41 were in the Faculty of Medicine; in the session preceding 144, of whom 70 were in medicine; and in the session 1881-82 they numbered 201, of whom 122 were in medicine. The decline is almost exclusively confined to the Faculty of Medicine, that department of the College which it was foreseen would be particularly affected by the reversal of the university system. The President trusts,

Digitized by Google

however, that the depression will be but temporary, and he is slow to relinquish the hope that the College will yet regain and even surpass its former position.

THE BELFAST ROYAL HOSPITAL.

A bazaar and fancy fair will shortly be held in aid of the funds of this institution. On the last occasion a very considerable sum was obtained. It is satisfactory to find that the working classes in Belfast have during the past year contributed liberally to this hospital, and that its claims to their support are thoroughly recognised. A pleasing example of this took place recently, when at a meeting of the assistant-managers, overlookers, and operatives in the weaving factory of the York-street Spinning Company it was decided to contribute a donation of £50, thus rendering the manager eligible as a life governor of the hospital.

BELFAST HOSPITAL SATURDAY.

A meeting of the Hospital Saturday Committee and of the collectors was recently held to receive the report of the Committee. The total receipts amounted to £564 7*s.* 1*d.*, the expenditure to £33 6*s.* 3*d.* The subject of a Hospital Saturday first came before the Belfast Royal Hospital Committee, next the co-operation of the Trades Council was obtained, and ultimately the movement was successful. Arrangements will be made to hold a Hospital Saturday collection next year.

Dublin, Oct. 14th.

PARIS.

(From our own Correspondent.)

FRENCH VIEWS OF CHOLERA.

AT the discussion at the meeting of the Academy of Medicine last week on Cholera, M. Ricord made a few remarks on the disease in question, which, although not in his specialty, he had an opportunity of studying in 1832 while surgeon to the Hôpital du Midi. The number of cases daily occurring in Paris was so great that it was found necessary to send out of the hospitals all the patients who were able to walk, to make room for those affected with cholera. In this way M. Ricord remarked that, notwithstanding the excessive mortality, not one of the patients who were retained in the hospital became affected with the disease, nor did any of the medical staff or *employés* of the hospital. Moreover, M. Ricord was at the time engaged in giving lectures on operative surgery, when the bodies of the patients dying from cholera were used for the purpose, and yet none of the students contracted the disease. From these circumstances M. Ricord concluded that cholera was not contagious, and that it originated spontaneously under the influence of some cause the nature of which has as yet not been determined. M. Ricord, on the ground of the non-contagiousness of the disease, condemned quarantine as being useless, delusive, and dangerous, at least so far as it concerned persons in health who were flying from infected quarters. At a previous meeting of the Academy Professor Bouchardat remarked that the cholerigenetic bacillus was never produced spontaneously in Europe, but was always imported, and that the contagiousness of cholera being incontestable, the disease is necessarily of parasitic origin. But he does not admit that the cholerigenetic parasite is the comma bacillus of Dr. Koch. M. Jules Guérin said that he had no confidence in the comma bacillus as a specific cause of the cholera, nor could he have more in the creature imagined by M. Bouchardat. He (M. Jules Guérin) never believed in the contagiousness of cholera, except under certain circumstances, or that it was ever imported, but that it was always produced spontaneously under the influence of local causes. Consequently, sanitary cordons and quarantines, whether by land or sea, are perfectly useless. This theory, and that of the identity of sporadic with Asiatic cholera, the learned Academician has maintained unshaken for the last fifty years.

Dr. Maurin of Marseilles delivered a public lecture on Monday last on the Etiology of Cholera. He began by stating it to be his firm belief that the outbreak of the disease was caused, not by importation as was supposed, but by the development of cholera germs that were buried with the patients who died from the disease during the epidemic in 1865 and 1866. A short time before the recent outbreak some of the streets of Toulon were macadamised with earth brought from the burial-ground where cholera patients were interred, and Dr. Maurin thought that the setting in of the disease about the time was something more than a simple coincidence, and if the theory of the parasitic origin of the disease was correct, there was here sufficient evidence of the two circumstances standing in the relation of cause and effect. Dr. Maurin, in conjunction with Dr. Lange, in their investigations on the subject, had discovered a substance which they believed to be the pathogenetic agent of the disease, and to which they have given the name of "le mucor cholerifé e." This substance is described as being a species of mushroom, of the class of "mucorinées," which is developed on the fourth or fifth day in the dejections of cholera patients. This mucor has an extraordinary power of vegetation. It lives in a 10 per cent. solution of carbolic acid, salicylic acid, and the strong acids. It continues its evolution in a 20 per cent. solution of corrosive sublimate or of chloride of zinc. It survives a temperature of 120° C. But its vegetation is arrested by a solution containing $\frac{1}{1000000}$th part of iodine in the cultures, and $\frac{1}{10}$th when the plant is developed. It is composed of a mycelium, from which start filaments which terminate in "sporanges" or bulbs containing a quantity of spores in a state of maturity. The sporanges open, and their spores, whose dimensions are only the hundredth part of a millimetre, fly about in all directions. The practical consequences of this discovery are, according to MM. Maurin and Lange, very important. It is evident from what has been said that the rational prophylaxis of cholera consists in treating the choleraic dejections with tincture of iodine, and submitting all the articles that have been in contact with cholera dejections to steam above 200° C. Dr. Maurin states that under the above notions as to the nature of cholera, one might understand the futility of quarantines, and the conveyance of the malady by air, by human beings, or by articles worn by them. It will also be understood why cholera is not immediately contagious. When the mucor cholérifère has found a favourable medium for its propagation it develops, and its spores are launched into the air and water. Every person then comes under the morbid influence during an epidemic, because these spores are more or less ingested by the healthy stomach; a very few only are developed into germ-ferments in the intestine. But if the stomach is weak or diseased, the spores are not digested, the ferment plants are developed, they extract oxygen and heat from the blood, and from the parietes of the stomach and intestines, whence all the phenomena of cholera which terminate by a general interstitial asphyxia, and death consequent on the deficiency of water and of chloride of sodium in the blood. Dr. Maurin does not believe in the comma bacillus of Dr. Koch, at least so far as regards the *rôle* assigned it by the German biologist in the etiology of cholera, Dr. Maurin considering that the bacillus stands in the same relation to the production of the cholera fermentation as the spirillum does to the acetious fermentation; consequently the bacillus is the result or product of the disease, and not its cause.

M. Arousshon, professor of chemistry, has been deputed by the Minister of Public Instruction to proceed to Italy to study the etiological aspects of cholera, and the effects upon it of applied therapeutics.

Paris, Oct. 15th, 1884.

ROYAL COLLEGE OF PHYSICIANS.

AT a special Comitia of the Royal College of Physicians on Thursday last (16th inst.), Sir W. Jenner, Bart., President, in the chair, a report was read from the representative of the College in the General Medical Council.

The College then proceeded to consider the question of the appointment of "representatives of the College on the Committee of Management for the Examining Board for England, constituted by the Royal College of Physicians and the Royal College of Surgeons." Dr. Quain moved that the question be postponed until the next meeting, and urged that the subject in all its bearings was not thoroughly understood by the Fellows. The motion was seconded by Dr. Braxton Hicks; but an amendment, proposed by Dr. Sieveking, and seconded by Dr. Bristowe, that

Digitized by Google

the nomination should be proceeded with, was carried almost unanimously. The following Fellows were nominated to serve on the Committee of Management: Sir H. Pitman, Dr. W. M. Ord, and Dr. Norman Moore.

ROYAL COLLEGE OF SURGEONS.

AT a quarterly meeting of the Council, held on Thursday, the 16th inst., the sanction of the General Medical Council was reported to the scheme for the conjunction of the Royal College of Physicians and the Royal College of Surgeons, under Section 19 of the Medical Act. Mr. Forster (the President) and Messrs. Marshall and Savory were appointed representatives of the College on the Committee of Management under this scheme. It was resolved that the regulations as to the curriculum of study should come into force from the 1st inst.

Mr. John Wood was re-elected a member of the Court of Examiners, and Mr. Henry Moon was elected a member of the Board of Examiners in Dental Surgery.

A committee of ten was appointed to consider and report to the Council what additional accommodation can be obtained for examinations and other purposes. It is desired to obviate the necessity of closing the library during the periods of examination.

The diploma of Member granted to Mr. Ebenezer Bryceson on April 26th, 1884, was recalled and declared to be void under Sect. 22 of the Charter of the 7th of Victoria.

A report was received that the College is the residuary legatee under the will of the late Sir Erasmus Wilson.

A letter from Mr. Wheelhouse relating to the uncertainty of the results of the examinations of the College was referred to the representatives of the College on the Committee of Management under the combination scheme.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on the 13th, 14th, and 15th inst.:—

Francis Pain, C. Stewart Pethick, W. Withers Ewbank, Percy H. V. Hammersley, Albert de Lisle, and Fred. R. Miller, St. Bartholomew's Hospital; J. Lorenzo Davison and Edw. Furrer, Toronto; Julius Z. Torres, Colombia; Fairlee R. Ozzard, Howell T. Evans, and Leonard Raby, London Hospital; Wm. H. Stevens and Arthur Leche, Bristol; George F. Johnston, John R. Davies, John T. Harvey, and William J. Morton, Edinburgh; Samuel H. Harrington, Liverpool; George W. Rowe and Edward T. Wynne, Cambridge; Jacob A. Nowell, Leeds; T. Alfred Robson, Andrew S. Brewis, Charles W. Steenberg, and Theodor Lund, Newcastle; William A. Loxton, Roger Bullock, and Alfred J. Bulger, Birmingham; William W. Paterson and John Huges, Glasgow; Edward H. Young, Edgar Jennings, and Lewis W. Pockett, University College; John H. E. Austin, Percy B. Mackay, and Harry R. Mansell, St. George's Hospital; Gerald C. Hayward, Middlesex Hospital; William F. W. Shells, Robert Thompson, and Joshua H. Harvey, Guy's Hospital.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on Oct. 9th the following degrees were conferred:—

DOCTOR OF MEDICINE.—William Edward Stevenson, Downing.

BACHELORS OF MEDICINE.—George Tucker Clapp, Charles Edward Henry Cotes, Gonville and Caius.

BACHELOR OF SURGERY.—Charles Edward Henry Cotes, Gonville and Caius.

The Examiners in State Medicine have issued the following list of those examined and approved for certificates in Sanitary Science:—

A. Allan, M.D. Edin.; C. J. Coverton, L.R.C.P. Edin.; John J. Eyre, L.K.Q.C.P. Ireland; D. A. Gresswell, M.B. Oxford; K. P. Ganta, F.R.C.S. Edin.; H. Handford, M.D. Edin.; J. B. Hurry, M.B. Cantab.; J. J. Macan, M.A., F.R.C.S.; T. J. M'Gann, F.R.C.S. Edin.; F. Marsh, F.R.C.S.; L. W. K. Phillips, F.R.C.S.; F. Welsh, F.R.C.S.; W. C. Wise, M.D. St. Andrews.

The Professor of Pathology (Dr. Roy) will deliver his introductory lecture on Monday, October 20th, in the lecture room of Comparative Anatomy, at two o'clock.

APOTHECARIES' HALL.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a certificate to practise, on Oct. 9th:—

John William Lynch, Commercial-road.

BY the agency of the Metropolitan Public Garden and Playground Association, eight open spaces have been obtained for public use during the past year.

THE sanitary authority of Canterbury have failed to obtain a magisterial order to enable them to close certain wells in the city which are believed to be contaminated.

ON the 15th inst. the Archbishop of Canterbury opened the Royal Alfred wing of the Croydon General Hospital, the foundation stone of which was eleven months since laid by the Duke of Edinburgh.

THE LATE DR. LESLIE OF ALTON.—A five-light stained-glass window of artistic design to the memory of the late Dr. Leslie has just been placed at the east end of the Alton parish church.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—An Entrance Science Scholarship of the value of £100 has been awarded to Francis Charles Abbott, and one of the value of £60 to Charles James Martin.

THE residuary estate of the late Mrs. Hatton, of Leeds, amounting to about £20,000, is to be divided amongst five local charities, amongst which are the Leeds Infirmary and the Cookridge Hospital.

ON the 15th inst. their Royal Highnesses the Prince and Princess of Wales paid a visit to the Norfolk and Norwich Hospital, the foundation stone of which was laid by the Prince in 1879, and expressed their great satisfaction at the efficient state of the institution.

PRESENTATION.—On the 4th inst., Dr. Lorimer was presented by the nurses and patients of the Devonshire Hospital, Buxton, with a valuable timepiece and an address, on his retirement from the post of resident medical officer to that institution, a position which he had held for many years.

FRIENDLY SOCIETIES AND HOSPITALS.—The sum of £100 has been handed over to the Great Northern Central Hospital authorities as the result of the demonstration of the Amalgamated Friendly, Temperance, and Trade Societies which was held on Sep. 7th.—A large temperance demonstration took place on Sunday afternoon at Brentford in aid of the London Temperance Hospital. It is estimated that between 3000 and 4000 members took part in the proceedings.

DEATH OF MR. WILLIAM EPPRETT.—Many of the numerous visitors to the Museum of the Royal College of Surgeons will be sorry to hear of the sudden death from angina pectoris, on the 9th inst., of this worthy and most zealous assistant in the Museum, who was an especial favourite of Professor Flower, as indeed he was with all the officers and servants of the College, some of whom testified by their attendance at Kensal-green the great respect in which they all held him.

GLASGOW SOUTHERN MEDICAL SOCIETY.—At the annual meeting of this Society, held in their rooms on the 9th inst., the following gentlemen were elected office bearers for the session 1884-85:—President: Dr. A. Napier; Vice-President: Mr. William Carr; Treasurer: Mr. E. Mac Millan; Secretary: Dr. David Tindall; Editorial Secretary: Mr. James Hamilton; Seal Keeper: Dr. Thomas Lapraik; Court Medical: Dr. Robert Park, Dr. A. Pearson, Dr. James Morton, Dr. James Barras, Dr. John White; Ordinary members to complete Council: Mr. John Glaister, Mr. W. J. Shaw, Mr. F. A. Freer.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The quarterly court of this Society was held in the room of the Royal Medical and Chirurgical Society on Oct. 8th; the President, Sir James Paget, F.R.S., in the chair. One new member was elected at the meeting, the election of a member was declared void, and the deaths of four were reported, including those of two vice-presidents—Mr. Cæsar Hawkins and Sir Erasmus Wilson. Dr. Quain moved, and Sir H. Pitman seconded, that the President be requested to communicate to Mrs. Hawkins and Lady Wilson an expression of the sincere

Digitized by Google

sympathy of the Board of Directors of the Society on the occasion of their great loss, and to Lady Wilson their grateful appreciation of the munificent legacy of £5000 bequeathed by Sir Erasmus Wilson. On the recommendation of the acting treasurer, Mr. Fuller, it was agreed to give the usual present at Christmas to the widows and orphans receiving grants from the Society. Applications for grants were read from fifty-nine widows, five orphans, and three orphans on the Copeland Fund, and it was resolved that a sum of £1259 be distributed amongst them at the next court. Applications were read for the first time from two widows and five orphans, and grants were made subject to the approval of the Committee of Visitors. Another application of a widow for herself and child was referred to the visitors to report on at the next court.

FIFESHIRE MEDICAL ASSOCIATION.—At the third annual meeting of this Association, held at St. Andrews on the 30th ultimo, the President, Dr. Archibald, read an address relative to the history of St. Andrews and her University. In it he dwelt upon the antiquity and long-standing importance of them both, and urged that, rather than let the old University perish, steps should be taken to bring its teaching possibilities fully up to the level of the times. He considered that, in the Medical Faculty, the addition of a chair, say of botany or materia medica, would allow of students taking out two *qui medici*, and would also tend to the strengthening of the Faculty as a centre for the teaching of science. Dr. Dow exhibited the skull and gave a short account of Lilias Adie, Torryburn, witch, with extracts from the Kirk-Session records relative to her trial and death, which was listened to with much interest. The following were elected as office-bearers for the ensuing year: Dr. Dow (Dunfermline), President; Dr. K. Macdonald (Cupar), Vice-President and Treasurer; Dr. Douglas (Cupar), Secretary; Drs. Archibald (St. Andrews) and Whitelaw (Cupar), Members of Council. The members afterwards adjourned to an hotel, where dinner was served and a most enjoyable evening spent.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—At the annual meeting of this College, held on the 15th inst., the following office-bearers were elected for the ensuing year:—President: John Smith, M.D., LL.D. Vice-President: William Turner, M.B. Secretary and Treasurer: Joseph Bell. Librarian: Archibald Dickson, M.D. President's Council: Henry Duncan Littlejohn, M.D.; Patrick Heron Watson, M.D.; David Wilson, M.D.; Francis Brodie Imlach; Douglas Argyll Robertson, M.D.; John Duncan, M.D.; William Turner and Joseph Bell (*ex officio*). Representative in General Medical Council: Patrick Heron Watson, M.D., LL.D. Examiners: James D. Gillespie, M.D.; Henry D. Littlejohn, M.D.; Patrick H. Watson, M.D., LL.D; David Wilson, M.D.; John Smith, M.D., LL.D.; Joseph Bell; John Duncan, M.D.; Robert J. Blair Cunningham, M.D.; Alexander G. Miller; Peter A. Maclaren, M.D.; Johnson Symington, M.B.; Francis Cadell; James Dunsmure (junior), M.D.; William Craig; Charles E. Underhill. Dental Examiners: Patrick H. Watson, M.D., LL.D.; Henry D. Littlejohn, M.D.; David Wilson, M.D.; John Smith, M.D., LL.D.; Andrew Wilson, L.D.S.; George W. Watson, L.D.S. Assessors: William Brown; Archibald Inglis, M.D.; James Dunsmure, M.D.; William Walker. Conservator of Museum: Robert J. Blair Cunningham, M.D. Clerk: James Robertson, Solicitor. Officer: Colin Mackenzie. Assistant to Conservator: George Reid.

Medical Appointments.

N.B.—This column must be sent DIRECT *to the Office of The Lancet before 9 o'clock on Thursday Morning at the latest.*

[illegible] has been appointed Assistant Medical [illegible] Old Town Infirmary, vice Beattie, re[illegible]

[illegible], L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer to the Buckingham Palace-road Workhouse, St. George's (Hanover-square) Union.

BRUCE, J. MITCHELL, M.D., F.R.C.P.I., has been appointed Consulting Physician to the Royal Caledonian Asylum, vice Dr. A. Wood, deceased.

CHADWICK, CHARLES M., M.A., M.B.Oxon., M.R.C.P.Lond., has been appointed Physician to the Leeds Public Dispensary, vice Thomas Courton, M.D., resigned.

CREAGH, WM., L.R.C.S.I., L.S.A.Lond., has been reappointed Medical Officer to the Lullington and Rosliston District of the Burton-upon-Trent Union.

FRASER, JAMES A., M.R.C.S., L.R.C.P.Lond., has been appointed Surgeon to the Romford Union House.

GIBSON, CHARLES JOHN, M.B., C.M.Ed., has been appointed Medical Officer for the Stone District and Workhouse, Stone Union, vice Hopkins.

HALL, B., M.B.Lond., M.R.C.S., has been appointed Second Assistant Medical Officer to the Middlesex County Asylum, Banstead.

HARTRIDGE, GUSTAVUS, F.R.C.S., has been appointed Consulting Ophthalmic Surgeon to St. Bartholomew's Hospital, Chatham, vice Henry Power, F.R.C.S., resigned.

HARVEY, FRED. GEORGE, M.R.C.S., has been appointed Medical Officer for the Acton Burnel District of the Atcham Union, vice Glover.

INGOLDBY, FREDERICK J., M.R.C.S., has been appointed Assistant Medical Officer and Dispenser to the Infirmary, Fulham Union.

JOHNSON, SAMUEL EBENEZER, L.S.A.Lond., has been appointed Medical Officer for the Balsall Heath District of the King's Norton Union.

MURDOCH, J. WM. A., M.B., C.M., has been appointed Resident Medical Officer to the Riccartsbar Asylum, Paisley, vice Dr. Park, resigned.

NUGENT, G. P. L'ESTRANGE, M.B., B.Ch.Dub., has been appointed Assistant-Physician and Pathologist to the House of Industry Hospitals, Dublin.

PIGEON, W. H., M.A., M.B., B.C.Camb., M.R.C.S., has been appointed Resident Surgical Officer to the Royal Infirmary, Manchester, vice Bilton Pollard, M.D. &c., resigned.

ROBINS, GEORGE NORMAN, M.R.C.S., L.R.C.P., has been appointed Medical Officer to the Rippingale District of the Bourne Union, vice Adams, resigned.

WILLIAMS, DAVID JOHN, M.D. St. And., F.R.C.S.E., has been appointed Acting Health Officer for the Port of Port Philip, vice Bulmer, resigned.

WILSON, FRANK, M.B., C.M., has been appointed Medical Practitioner to the Paisley Infirmary, vice Dr. Dickson, resigned.

Births, Marriages, and Deaths.

BIRTHS.

BENNETT.—On the 8th inst., at Upper Berkeley-street, Portman-square, the wife of H. Selfe Bennett, M.B., of a son.

BRUNTON.—On the 11th inst., at Welbeck-street, the wife of T. Lauder Brunton, M.D., of a son.

HIND.—On the 11th inst., at Whitehall-place, Stockton-on-Tees, the wife of Henry Hind, F.R.C.S., of a daughter.

TUKE.—On the 20th ult., at Ranelagh House, Chiswick, the wife of Charles Molesworth Tuke, M.R.C.S., of a daughter.

WHITTINGTON-LOWE.—On the 10th inst., at Marine-parade, Brighton, the wife of R. Whittington-Lowe, M.D., Staff-Surgeon, of a daughter.

MARRIAGES.

BRYCESON—LAWSON.—On the 2nd inst., at Rectory-place Church, Woolwich, Ebenezer Bryceson, M.A., M.B.Camb., M.R.C.S., and L.S.A.Lond., second son of George Bryceson, Esq., of Shooter's-hill, Kent, to Jessie Ellen, second daughter of James Lawson, Esq., of Tilbury Villa, Fox-hill, Plumstead.

BUTTON—GARRARD.—On the 1st inst., at Tickenhall, Derbyshire, Henry Herbert Walter Button, L.R.C.P.Ed., L.F.P.S.Glasg., to Kate Garrard, second daughter of the late William Garrard, Esq., of Tickenhall, Derby.

JAMES—PERKINSON.—On the 7th inst., at the Parish Church, Bradford, Yorkshire, by the Rev. Canon Bardsley, D.D., Vicar of Bradford, assisted by the Rev. Knight Gale, Vicar of St. Andrew's, Bradford, the Rev. Gilbert Leny James, Vicar of Gresley, Derbyshire, to Mary Elizabeth, eldest daughter of the late William Parkinson, Esq., M.R.C.S. Eng., L.S.A.Lond., of Bradford.

JOHNSTONE—VAWDREY.—On the 7th inst., at St. Mary's, Handsworth, William Johnstone, L.R.C.S., L.S.A.Lond., of Smethwick, to Mary Leah, youngest daughter of the late Thomas G. Vawdrey, M.R.C.S., L.S.A.Lond., of St. Austell.

MILLAR—LIBERTY.—On the 7th inst., at St. Andrew's Church, Nottingham, by the Rev. Canon Morse, M.A., assisted by the Rev. Frederick Hart, B.A., James Millar, M.D., of Sowerby Bridge, Yorkshire (late of Asbroath, N.B.), to Kate, eldest daughter of Arthur Liberty, of Nottingham.

SMITH—RUSSELL.—On the 7th inst., at St. Luke's, West Holloway, T. F. Hugh Smith, F.R.C.S., eldest son of Henry Smith, F.R.C.S., of 82, Wimpole-street and the Orchard, Swanley, to Florence Mary, elder daughter of the late James Russell, of Charton, Faringham.

DEATHS.

BURNETT.—On the 9th inst., at Dover, Ferdinand Burnett, M.D., in his 81st year.

GUISE.—On the 4th inst., at The Knoll, Clifton, Surgeon-General Guise, late of Bengal, aged 68.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, October 20.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Address by the President. Paper by Sir Joseph Lister, Bart.—At 8 P.M. a New Invalid Bed-lift will be shown by Mr. Newham.

Tuesday, October 21.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Charlewood Turner and Dr. Carrington: Dysenteric Abscesses in Liver.—Dr. Wickham Legg and Dr. Theodore Acland: Cases of Hæmophilia and Purpura.—Mr. Pepper and Dr. Silcock: Tabes Dorsalis, with Perforating Ulcer of the Foot.—Dr. Hadden: Two Fatal Cases of Alcoholic Paralysis.—Dr. Hale White: Coarctation of the Aorta, Chronic Ulcer of the Stomach, with Secondary Changes in the Pancreas (card).—Dr. Ormerod: A Case of Scleroderma.—Dr. J. F. Payne and Dr. F. Semon: Rhino-Scleroma (living).

Wednesday, October 22.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays, at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.—Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department, 1.45 P.M., and on Saturday at 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

HUNTERIAN SOCIETY.—8 P.M. Dr. Thorowgood: Some forms of Irritable Heart.

Thursday, October 23.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

Friday, October 24.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

QUEKETT MICROSCOPICAL CLUB.—8 P.M. Dr. W. B. Carpenter, F.R.S. (President): The Relations of the Various Types of the Genus Orbitolites.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Golding-Bird: A Case of Dislocation of the Patella.—Dr. James Anderson: A Case of Myxœdema.—Dr. Carrington: A Case of Eruption probably due to Bromism.—Mr. Godlee: A Case of Nephrectomy for Tumour in an Infant.—Dr. J. K. Fowler: Pigmentation of Tongue (living specimen).

Saturday, October 25.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to the Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

"AN IMPUDENT DEFENCE OF CANNIBALISM."

THE writer in the *Catholic Times* seems aggrieved at our remarks on his annotation on the terrible incident in connexion with the loss of the *Mignonette*. We readily accept his entire disclaimer of any sympathy with those who are disposed to extenuate murder for the purposes of cannibalism. We must still, however, object with some indignation to his statement that "it is no uncommon thing for doctors to administer to persons who appear to be, and probably are, dying of painful diseases, such drugs as not only allay pain, but will also surely hasten their end." This is an unwarrantable statement. We reproduce some remarks of our contemporary of last week on this matter:—

"Our accuser is by far the leading medical journal in England, and has a world-wide circulation. We are therefore at a loss to understand how its acute editor could fail to see that our comments were at one with his own opinions on the subject of murder and human flesh-eating. We can only conceive that a correspondent sent the editor a copy of our paper with the article marked, and that, the name 'Catholic' recalling the false stories of his school-days, he merely glanced hastily over the lines, and, seeing that it was about cannibalism, took it for granted that it must have been a defence of the barbarous crime. To read a sentence at haphazard was, of course, sufficient. This random sentence happened to contain an allusion to the doctors, and this riveted his attention. In using the word 'doctors' we meant 'some doctors.' But he exaggerates our observations into a charge against the whole medical profession. Nothing, however, could have been further from our intention. We gladly recognise that, whatever the profession may be in foreign countries, its twenty thousand British members are a noble band, whose earnest and self-sacrificing efforts to stay the ravages of disease, drunkenness, and crime, merit for them the gratitude and esteem of the community. In daily intercourse they are kind and considerate to our poor; and they are ever courteous to our clergy."

RIDING *v.* DRIVING.

To the Editor of THE LANCET.

SIR,—I should be glad, with your permission, to obtain the opinions of my professional brethren engaged in rural practice as to the comparative advantages of riding or driving on their journeys. I formerly had a country practice, purely rural, in which my rounds were usually twenty, and sometimes thirty, miles a day, and I always drove. The most handy vehicle for such work is, in my experience, a square shooting-cart with adjusting seat. I also used a Stanhope gig; but it is decidedly less safe and not so comfortable. Four-wheels are safest of all; but everyone in country practice knows that they wear out the horse, and are less expeditious; and expedition, with due regard to the horse, must be the first consideration. Is riding safer; especially at night? And would it be safe for a man not much accustomed to the saddle of late years and rather past middle age? Driving is probably more comfortable in cold or wet weather. I may remark I never used a hooded gig, as it adds to the weight and catches the wind; they are more used by practitioners in towns, and for short journeys. Hansom cabs, *et hoc genus omne*, are not worth consideration for long distances and cross-country roads. Cobs of about fourteen hands are more useful than full-sized horses. I preferred having a light-weight groom to drive, as I always found it adds very much to the fatigue to drive oneself, though many I know do so; it is certainly safer, as all my accidents were the result of grooms' driving. Accidents are common to most practitioners who are out a good deal by day and night. I do not know if any difference exists in the risks of riding or driving. I have known many fatal accidents happen both ways. Perhaps some of your readers will kindly give their opinions on this point.

I am, Sir, yours truly,

Oct. 6th, 1884. ATRA CURA POST EQUITEM SEDET.

SUICIDES IN FRANCE.

OFFICIAL returns recently published show that in France the number of persons ending their lives by suicide is increasing in a remarkable manner. Five years ago the proportion of self-destroyers per 100,000 inhabitants was seventeen, now it is nineteen. Hanging and drowning appear most commonly resorted to, the modes of destruction next in favour being by firearms or charcoal fumes. The months of April, May, and June are those in which the highest number of suicides take place, there being, it is also remarked, generally fewer cases of self-inflicted death during the last than during the first three months of the year.

Mr. W. H. Bull.—References to cases in point will be found in THE LANCET of Feb. 16th, 1877, p. 223; Jan. 24th, 1880; Dec. 9th, 1882. But each case must, of course, stand on its own merits.

J. M. T. (Liverpool).—Yes. Dr. Fauvel, we believe, still holds to the view that the disease which has prevailed in France is different in kind from that which is witnessed in the East.

G. H. F.—The subject has already been thoroughly discussed in our columns.

J. H. R.—One swallow does not make a summer.

Devonian should consult his medical adviser. We do not prescribe.

A MODIFICATION OF DR. JUNKER'S INHALER.

To the Editor of THE LANCET.

SIR,—Dr. Buxton's paper on the above subject, which appeared in your issue of Oct. 4th, bears strong testimony in favour of this apparatus, which was first constructed by our firm in 1867, and has since been widely adopted by the medical profession in England and abroad, where it has been from that time in constant use in the principal hospitals and surgical clinics. This inhaler, it will be remembered, although originally designed for the administration of methylene—the use of which, however, has always been, at any rate on the Continent, very limited—owes the favour it has generally met with principally to its admirable efficacy and advantageousness for the administration of chloroform. One of its many advantages is that a much smaller quantity of the narcotic is required to produce and to keep up full narcosis than by other methods, but little more than one drop being the most which can be evaporated and administered with each compression of the bellows.

We admit that Dr. Buxton's modification of refilling the reservoir may have its advantage, provided the peg fit securely, which will not always be the case. If too tight, it will oppose great resistance at its removal; if too loose, it will be lifted and pushed out by the internal pressure of the air pumped into the receiver. Our screw-top obviates the latter accident, and its removal will barely cause more delay than that of a tight peg. The objection that the administrator has not a hand at liberty for any emergency will easily be overcome by a little skill and practice. We have repeatedly witnessed Dr. Junker's method, who manages, if necessary, with the same hand to hold the face-piece, to compress the bellows, and to feel the pulse of the maxillary artery, thus leaving the other hand free. The treadle for working the air-ball, instead of compressing it with the hand, has been introduced from the earliest date. Some administrators find it more convenient, while others return to the hand-bellows. The material of the face-piece is likewise a matter of individual preference; it has been made of leather, felt, flannel, and even of paste-board. We are, however, inclined to believe that a vulcanite face-piece is cleaner and more durable. The face-pieces we supplied to the Samaritan Hospital in 1867 are still in use, and are none the worse for wear. The face-piece should be held before, or but lightly against, the patient's face, when it will not leave any mark of pressure. The air-cushion adjustment around the rim of the face-piece has also had its trial; but it was quickly abandoned, and justly so, for the patient is not to breathe, and cannot breathe freely through the inhaler. Junker's inhaler appears to be misunderstood by many; for it seems not to be taken into account that by pressing the air-bellows the narcotic vapour is brought before the patient's face and nose in a concentrated condition, even if only two drachms of the anæsthetic be in the bottle, which must be diluted with not less than five times as much fresh atmospheric air, which should enter freely at the sides and valve of the face-piece. A closely fitting face-piece is therefore objectionable. A pocket-handkerchief folded lengthways and bound around the rim serves more efficiently; it does not prevent the easy breathing of the patient, is clean and safe, and does away with the necessity of a series of face-pieces. We are, Sir, yours obediently,

London, Oct. 13th, 1884. KRONNE & SESEMANN.

GLASGOW UNIVERSITY PROFESSIONAL EXAMINATIONS.

IN our Glasgow Correspondent's letter last week the number of candidates for professional examination at the University was accidentally misstated. The numbers should have been as follows: For the first examination, 156; for the second, 85; for the third, 62—numbers strongly suggestive of a weeding-out process.

A Student will find all the information he desires in our Students' Number, published on Sept. 13th.

Mr. Edward Lucas.—The matter is referred to in another column.

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE first Primary Examination for the Membership of the College for the present session was commenced on Friday, the 10th inst., when 136 candidates presented themselves, against ninety-four at the corresponding period of last year. The following were the questions on Anatomy, and the candidates were required to answer four, and no more, between the hours of 1 and 3 P.M.:—

1. Describe Hunter's canal; its boundaries and contents. Mention the parts in relation to it.
2. Give the dissection required to expose the suboccipital triangle.
3. Give the attachments and relations of the pronator radii teres.
4. Enumerate the sutures of the cranium. Give their course, the bones which respectively enter into their formation, and the class of suture to which they severally belong.
5. Describe the origin, course, and termination of the saphenous veins, and enumerate their chief tributaries.
6. Give the attachments and relations of the pharynx.

The following were the questions on Physiology, to be answered between the hours of 4 and 6 P.M.:—

1. Describe the structure and uses of the different forms of cartilage met with in the human body.
2. What is the pulse? Why is it in general confined to the arteries? Under what circumstances does it appear in the capillaries and veins?
3. Describe the nervous mechanism of respiration? By what conditions, and in what manner, may the rhythm of respiration be modified.
4. Describe the distribution of blood in the liver. By what forces is the movement of the blood through this organ maintained?
5. What gases are contained in the blood? State the average amount of these gases in arterial and venous blood? How may these quantities be determined?
6. Describe the structure of the cornea. Name the refractive media of the eye in the order of their relative importance.

Mr. J. M. Waters.—As a rule, the passing of an examination is required before permission is given to practise in the countries mentioned.

SCARLATINA LATENS.

To the Editor of THE LANCET.

SIR,—On Friday, Sept. 19th, I was summoned to see two children—Maggie B——, aged three years, and William B——, eight years—who had been ill since the 15th. On that day a swollen gland was observed in both at the angle of the jaw. On the 16th their faces appeared puffy, especially about the eyes, this gradually increasing till the morning of the 18th, when the parents saw that the ankles were increased in size. They also noticed that their children were passing very little urine. Matters got worse till the morning on which I was summoned (the 19th). On examination of the urine I found great abundance of albumen in that of the girl, but none in that of the boy. I prescribed a compound jalap powder and a diuretic mixture of digitalis, with potash and broom, and poultices to the loins. The boy got gradually better under this treatment, and so I shall only refer to the girl. On the 20th only an ounce of urine was passed in the morning, and none the rest of the day. In the evening the patient's temperature was 103·5°, and she was very drowsy. I ordered a leech over each kidney, which temporarily relieved them, and the patient passed urine three times between that and the forenoon of the next day.—21st: Evening temperature, 103·2°; pulse, 108; respiration, 106, and tubular in character. The patient had vomited twice in the afternoon. To relieve the dyspnœa I prescribed a leech over the top of the sternum, the bleeding to be encouraged by fomentations. This gave immediate relief.—22nd: Morning temperature normal; pulse, 104; respiration, 50. Evening temperature, 100°; respiration, 60. From this date the patient was convalescent.—Oct. 4th: The urine, when allowed to stand fifteen minutes after adding nitric acid, showed a faint ring of albumen.

In these cases there was no history of sore-throat or rash, and examination revealed no desquamation; but in both there was a swollen gland, renal dropsy, and diminished urine, with albumen in the one and none in the other, as we sometimes find in scarlatinal dropsy.

I am, Sir, yours truly,

Glasgow, Oct. 6th, 1884. JAMES WILSON, M.D., B.Sc., M.B.

CHECKING GROWTH OF THE HAIR.

To the Editor of THE LANCET.

SIR,—In answer to a correspondent who asks in your last issue if the growth of hair on different parts of the body can be stopped, I beg to observe that if ordinary depilatories will not destroy the hairs sufficiently, electrolysis should be employed. I have pursued this method for some time with much success. I am, Sir, your obedient servant,

Sackville-street, W., Oct. 13th, 1884. JAMES STARTIN.

To the Editor of THE LANCET.

SIR,—I would refer your correspondent to Section 21:2 of the Medical Digest, where, under the heading "Depilatories," will be found all the suggestions that have been made by different contributors to the medical papers during many years past.

I am, Sir, yours obediently,

South Hampstead, N.W., Oct. 14th, 1884. RICHARD NEALE, M.D.

ENGRAVINGS OF REMBRANDT'S PICTURES.

IN answer to several correspondents, we may say that copies of the engravings noticed by us last week may be obtained by order of Messrs. Williams and Norgate, Henrietta-street, Covent-garden, London, W.C.

Microbe.—See Dr. Timothy Lewis's letter in our issue of Sept. 20th, and our comments thereon in the same number.

Mr. Theodore Ewart (Salisbury).—The paper will appear shortly.

THE DEHYDRATION OF BODIES.

To the Editor of THE LANCET.

SIR,—You were kind enough in your last issue to notice my suggested process of dehydrating human bodies by a current of cool, dry, and germ-free air, and to express your opinion that it would afford one method of overcoming the disadvantage which cremation at present lies under of placing facilities in the way of poisoners. You naturally, however, reserve your opinion as to the practicability of the suggested process; and therefore I trust you will allow me space to point out that the process of mummification goes on spontaneously and successfully under conditions less favourable than those I recommend. The bodies buried in the vaults beneath the ancient church of St. Michan's in Dublin do not putrefy, but dry up to a species of mummy. This remarkable result is brought about, according to Drs. Cameron and Tichborne, who have investigated the matter independently, by the dryness of the air in the vaults and the absence of dust, and consequently of putrefactive bacteria. If this natural mummification is effected by dry germ-free air in the absence of antiseptics, it would seem to follow that a more perfect result would be obtained by the use of a current of air not merely dry in the popular sense, but chemically desiccated and freed from bacteria, especially as it would be easy to reduce the temperature to that indicated in the cold rooms of meat-carrying steamers traversing the tropical seas. As regards the production of the Egyptian mummies, I believe the function performed by the so-called antiseptics was much less important than is sometimes imagined. The molten asphalte or resin which was poured into the various cavities of the body was, I think, useful in filling them up, and so preventing them acting as reservoirs of air. The pickling process (for such it was), of course, tended to prevent immediate decay; but the efficacy of the process was for the most part due to the linen bandages which were so carefully and skilfully applied. The embalmers sometimes placed a thousand yards of linen upon a mummy, and they were very careful to avoid enclosing spaces of air. The linen, while not preventing the access of air and the consequent (perhaps slow) desiccation of the tissues, effectually filtered off the bacteria, and so prevented putrefactive change. In conclusion, I should like to say that the process I advocate is not really complicated. The owners of cargoes worth thousands of pounds constantly entrust them for months upon the ocean to the action of freezing machines, not furnished in duplicate, and the desiccation and filtration of air would offer no difficulty to the chemical engineer.

I am, Sir, yours faithfully,

Birmingham, Oct. 8th, 1884. THOMAS BAYLEY.

C. J. P.—We know nothing of the nostrum mentioned, and cannot undertake to warn the public against individual quack medicines.

Mr. Macdonald Brown (Edinburgh).—The lecture will appear in an early number.

Mr. W. H. Kesteven.—The article will be published shortly.

J. W.—Our correspondent, in our opinion, has no claim.

MANY communications are unavoidably held over till next week.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Box, Bristol; Mr. Watt; Mr. P. Ness, London; Mr. Elliott, Carlisle; Dr. Sexton, New York; Mr. Oakley, London; Mr. Macdonald Brown, Edinburgh; Mr. M. Martin, Glasgow; Mr. Perceval; Dr. Macalister, Cambridge; Mr. Knagga, Trinidad; Dr. Ormsby, Dublin; Mr. Ogier Ward, Tottenham; Mr. Headley Neale, Leicester; Mr. Henry Lee, London; Professor Wharton Jones; Dr. Crutchley, Holmcroft; Mr. H. Sewill, London; Dr. C. T. Ewart; Mr. Birchall, Liverpool; Mr. McGill, Leeds; Mr. Greenish, London; Mr. Taylor, Davos Platz; Dr. Marsden, London; Mr. Scott, Manchester; Mr. Percival, Leamington; Mr. Dority, Worcester; Mr. A. The Harveian Oration

DELIVERED AT THE

ROYAL COLLEGE OF PHYSICIANS,

October 17th,

BY J. RUSSELL REYNOLDS, M.D., F.R.C.P.,

FELLOW OF THE ROYAL SOCIETY,
PHYSICIAN IN ORDINARY TO H.M.'S HOUSEHOLD,
EMERITUS PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AT UNIVERSITY COLLEGE.

SIR WILLIAM JENNER, HONOURED PRESIDENT OF THIS LEARNED COLLEGE,—Before entering on the subject which now brings us here, I must ask you to accept my thanks for the distinction you have conferred on me in selecting me for the office I have the honour to fill to-day—an honour, allow me to add, which carries with it a special gratification to myself, inasmuch as among the many distinctions conferred by this College on my grandfather, the late Dr. Henry Revell Reynolds, there was not one he prized more highly than that of having delivered, as he did, before the President and Fellows of this College, one hundred and eight years ago, the Harveian Oration.

MR. PRESIDENT, FELLOWS OF THIS COLLEGE, AND GENTLEMEN,—Sir Thomas Browne has said, in one of his sadder moods, "Our fathers find their graves in our short memories, and sadly tell us how we may be buried in our survivors. ..... The greater part must be content to be as though they had not been—to be found in the register of God, not in the memory of man." This is without doubt true, as he said, of the "greater part," but it is not true of all; for our meeting here to-day is an assertion that there is, at least, one who has not yet found his grave in our vanishing powers of recollection, but whose life, unburied, still breathes in the lives of living acting men.

It is not of the sorrows and "unavailing tears" that were shed, nearly 230 years ago, over Harvey's grave, that it behoves me now to speak; but rather of the fact that although the knells of nearly three centuries have been tolled since he became a part of this College, yet that only last year, on Oct. 18th, our College repaired to his grave in Hempstead to do honour to his memory, and with gratitude and gladness to assert, as we do again to-day, that he still lives "in his survivors," and that, although 306 years have passed since Harvey's life began, he at the present hour is neither dead nor sleeping.
